This API is used for working with solution versions based on `ClassificationSolution` API objects in the `ClassificationSolution` store.

The system creates a solution version each time you train a solution definition. Most versions are created during scheduled solution training.

Methods in this API are accessible using the following `ClassificationSolution` methods:

- `getActiveVersion()`
- `getAllVersions()`
- `getLatestVersion()`
- `getVersion()`

### ClassificationSolutionVersion - getPredictionPerformance(Object options)

Calculates solution precision and coverage.

To use this method, you must first create settings using the `setPredictionSettings()` method.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Object</td>
<td>Selects a metric to retrieve within a span of dates. For more information, see <a href="#">Configuring target metrics</a>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{</td>
</tr>
</tbody>
</table>
|            |          |   "metricName" : "String",
|            |          |   "fromDate" : "String",
|            |          |   "toDate" : "String"
|            |          | }                                                                                                                                                                                                         |
| options.metricName | Name of the metric. Valid values: • precision • coverage |                                                                                                                                                                                                      |
| options(fromDate) | Optional. Start date from which to retrieve metrics in system date time format.                                                               |
| options(toDate)   | Optional. End date from which to retrieve metrics in system date time format.                                                                   |

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Parseable JavaScript object containing the results for the input metric.</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
</tbody>
</table>
|               |   "metricName" : "String",
|               |   "metricValue" : "String",
|               |   "numberOfPredictionsConsidered" : "String"
|               | }                                                                                                                                              |
| Object.metricName | Name of metric selected as input. Data type: String                                                                                         |
| Object.metricValue | Value of the selected metric. Data type: String                                                                                             |
| Object.numberOfRecordsConsidered | Number of records in the Predictor Results [ml_predictor_results] table considered for calculations.                                      |
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

The following example shows how to get a precision value from the active version of a solution.

```javascript
// Get precision value
var mlSolution = sn_ml.ClassificationSolutionStore.get('ml_incident_categorization');

gs.print(JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getPredictionPerformance({
  "metricName": "precision"})), null, 2));
```

Output:

```
{
  "metricName": "precision",
  "metricValue": "70.10",
  "numberOfPredictionsConsidered": "10"
}
```

**ClassificationSolutionVersion - getPredictionSettings()**

Gets estimated precision, estimated coverage, estimated recall values from the ML Solutions [ml_solution] table and records from the Class Confidence [ml_class] table.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Returns prediction settings for each class. Data includes precision, coverage, recall, and distribution values of all classes included in the trained model from the ML Solutions [ml_solution] table. For details, see Predictive model components.</td>
</tr>
</tbody>
</table>
## Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;Object&gt;.&lt;class name&gt;</code></td>
<td>Array of objects providing training statistics data from the Class Confidence [ml_class] table. For more information, see <a href="#">Configuring target metrics</a>.</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.&lt;class name&gt;.precision</code></td>
<td>Estimated solution precision metric for this class. Data type: String (numerical value)</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.&lt;class name&gt;.coverage</code></td>
<td>Estimated solution coverage metric for this class. Data type: String (numerical value)</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.&lt;class name&gt;.recall</code></td>
<td>Estimated solution recall metric for this class. Data type: String (numerical value)</td>
</tr>
</tbody>
</table>

The following example shows how to get prediction settings of an active solution version.

```javascript
var mlSolution = sn_ml.ClassificationSolutionStore.get('ml_incident_categorization');

gs.print(JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getPredictionSettings()), null, 2));
```

Output:

```json
{
  "solutionSettings": {
    "precision": "61.69",
    "coverage": "66.75",
    "recall": "57.54"
  },
  "classSettings": {
    "Approvals": {
      "precision": "100",
```
ClassificationSolutionVersion - getProperties()

Gets solution object properties and version number.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Contents of the Dataset and ClassificationSolution version details. Results vary by object property setup.</td>
</tr>
</tbody>
</table>

```json
{
    "algorithmConfig": {
        "algorithm": "String",
        "targetClassRecall": "String"
    },
    "datasetProperties": {Object},
    "domainName": "String",
    "encoder": {Object},
    "groupByFieldName": "String",
    "inputFieldNames": [Array],
    "isActive": "Boolean",
    "label": "String",
    "name": "String",
    "predictedFieldName": "String"
}
```
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returns (continued)</td>
<td></td>
</tr>
<tr>
<td><code>algorithmConfig</code></td>
<td>Method for encoding the solution.</td>
</tr>
<tr>
<td><code>algorithmConfig.algorithm</code></td>
<td>Name of the encoding algorithm for training this solution. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• <code>xgboost</code>: XGBoost encoding to optimize the training.</td>
</tr>
<tr>
<td></td>
<td>• <code>logisticRegression</code>: Method using the logistic regression model for categorical targets such as nominal or ordinal.</td>
</tr>
<tr>
<td><code>algorithmConfig.targetClassRecall</code></td>
<td>Class recall parameter to steer a solution's training to bias a specific class. The recall value is a number between 0 and 100 representing a percentage.</td>
</tr>
<tr>
<td><code>datasetProperties</code></td>
<td>Properties of the <code>DatasetDefinition()</code> object associated with the solution.</td>
</tr>
<tr>
<td></td>
<td>`{</td>
</tr>
<tr>
<td></td>
<td>&quot;encodedQuery&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;fieldDetails&quot;: [Array],</td>
</tr>
<tr>
<td></td>
<td>&quot;fieldName&quot;: [Array],</td>
</tr>
<tr>
<td></td>
<td>&quot;tableName&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td><code>datasetProperties.tableName</code></td>
<td>Name of the dataset. For example, <code>&quot;tableName&quot; : &quot;Incident&quot;</code>.</td>
</tr>
<tr>
<td></td>
<td>Data type: String.</td>
</tr>
</tbody>
</table>

<td>&lt;Object&gt;.domainName</td>
<td>Domain name associated with this dataset. See Domain separation and Predictive Intelligence. Data type: String.</td>
</tr>
<tr>
<td>&lt;Object&gt;.encoder</td>
<td>Encoder object assigned to this solution. See Encoder - Encoder(Object config). Data type: Object.</td>
</tr>
<tr>
<td>&lt;Object&gt;.groupByFieldName</td>
<td>Field name by which the system groups records to build classification solutions. Data type: String.</td>
</tr>
<tr>
<td>&lt;Object&gt;.inputFieldNames</td>
<td>List of input field names as strings. The model uses these fields used to make predictions.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.isActive</td>
<td>Flag that indicates whether this version is active. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Version is active.</td>
</tr>
<tr>
<td></td>
<td>• false: Version is not active.</td>
</tr>
</tbody>
</table>

Data type: String

<table>

<tr>
<th>&lt;Object&gt;.name</th>
<th>System-assigned name.</th>
</tr>
</thead>
</table>

Data type: String

<table>
<thead>
<tr>
<th>&lt;Object&gt;.predictedFieldName</th>
<th>Identifies a field to be trained for predictability.</th>
</tr>
</thead>
</table>

Data type: String

<table>
<thead>
<tr>
<th>&lt;Object&gt;.processingLanguage</th>
<th>Processing language in two-letter ISO 639-1 language code format.</th>
</tr>
</thead>
</table>

Data type: String

<table>
<thead>
<tr>
<th>&lt;Object&gt;.scope</th>
<th>Object scope. Currently the only valid value is global.</th>
</tr>
</thead>
</table>

Data type: String

| <Object>.stopwords         | Optional. Preset list of strings that the system automatically generates   |
|-----------------------------| based on the language property setting. For details, see Create a custom |
|                              | stopwords list.                                                            |
|                              |                                                                             |
|                              |                                                                             |
|                              |                                                                             |
|                              |                                                                             |

Data type: Array

<table>
<thead>
<tr>
<th>&lt;Object&gt;.trainingFrequency</th>
<th>Frequency to retrain the model.</th>
</tr>
</thead>
</table>

Possible values:
• every_30_days
• every_60_days
• every_90_days
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• every_120_days</td>
</tr>
<tr>
<td></td>
<td>• every_180_days</td>
</tr>
<tr>
<td></td>
<td>• run_once</td>
</tr>
<tr>
<td>Default: run_once</td>
<td>Data type: String.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>&lt;Object&gt;.versionNumber</th>
<th>Version number of the ClassificationSolution object.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type: String.</td>
<td></td>
</tr>
</tbody>
</table>

The following example gets properties of the active object version in the store.

```javascript
// Get properties
var mlSolution = sn_ml.ClassificationSolutionStore.get('ml_incident_categorization');

gs.print(JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getProperties()), null, 2));
```

**Output:**

```javascript
*** Script: {
"datasetProperties": {
"encodedQuery": "activeANYTHING\^EQ",
"fieldNames": [
"short_description",
"category"
],
"tableName": "incident"
},
"domainName": "global",
"inputFieldNames": [
"short_description"
],
"isActive": "true",
"label": "Incident Categorization_Trainer",
"name": "ml_incident_categorization",
"predictedFieldName": "category",
"processingLanguage": "en",
"stopwords": [
"Default English Stopwords"
]}
```
ClassificationSolutionVersion - getStatus(Boolean includeDetails)

Gets training completion status.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>includeDetails</td>
<td>Boolean</td>
<td>Flag that indicates whether to return status details. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Return additional details.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not return additional details.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: False</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>JavaScript object containing training status information for a ClassificationSolution object.</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;state&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;percentComplete&quot;: &quot;Number as a String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;hasJobEnded&quot;: &quot;Boolean value as a String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;details&quot;: {Object}</td>
</tr>
<tr>
<td>&lt;Object&gt;.state</td>
<td>Training completion state. If the training job reaches a terminal state, the job does not leave that state. If the state is terminal, the hasJobEnded property is set to true. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• fetching_files_for_training</td>
</tr>
<tr>
<td></td>
<td>• preparing_data</td>
</tr>
<tr>
<td></td>
<td>• retry</td>
</tr>
<tr>
<td></td>
<td>• solution_cancelled (terminal)</td>
</tr>
<tr>
<td></td>
<td>• solution_complete (terminal)</td>
</tr>
</tbody>
</table>

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>solution_error</td>
<td>(terminal)</td>
</tr>
<tr>
<td>solution_incomplete</td>
<td></td>
</tr>
<tr>
<td>training_request_received</td>
<td></td>
</tr>
<tr>
<td>training_request_timed_out</td>
<td>(terminal)</td>
</tr>
<tr>
<td>training_solution</td>
<td></td>
</tr>
<tr>
<td>uploading_solution</td>
<td></td>
</tr>
<tr>
<td>waiting_for_training</td>
<td></td>
</tr>
</tbody>
</table>

Data type: String

<Object>.hasJobEnded: Flag that indicates whether training is complete.
- Valid values:
  - true: Training is complete.
  - false: Training is incomplete.
- Data type: Boolean value as a String

<Object>.percentComplete: Number between zero and 100 representing training percent complete. If the completion percentage is less than 100, the job might be in a terminal state. For example, if training times out.
- Data type: Number as a String

<Object>.details: Object containing a list of additional training details.
- Data type: Object

The following example shows a successful result with training complete.

```javascript
// Get status
var mlSolution = sn_ml.ClassificationSolutionStore.get('ml_incident_categorization');

gs.print(JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getStatus(true), null, 2)));
```

**Output:**

```json
{
    "state":"solution_complete",
```
The following example shows an unsuccessful result with training complete.

```javascript
// Get status
var solutionName = 'ml_x_snc_global_global_classification_solution';
var mlSolution = sn_ml.ClassificationSolutionStore.get(solutionName);
var trainingStatus = mlSolution.getLatestVersion().getStatus();

gs.print(JSON.stringify(JSON.parse(trainingStatus), null, 2));
```

Output:

```
{
  "state": "solution_error",
  "percentComplete": "100",
  "hasJob Ended": "true"
}
```

### ClassificationSolutionVersion - getTrainingStatistics()

Gets all the training statistics for a given solution.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>JavaScript object with statistics for each class included in training and values for each class that was excluded from training. For details, see <a href="#">Predictive model components</a>.</td>
</tr>
</tbody>
</table>

```javascript
{
  "includedClasses": Object,
  "excludedClasses": Object
}
```
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.includedClasses</td>
<td>Object containing precision, coverage, recall, and distribution values of each class in the trained model.</td>
</tr>
</tbody>
</table>

```
"includedClasses": {
"<class name>": {
  "distribution": "String",
  "statistics": [Array]
},
```

Data type: Object.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.includedClasses.&lt;class name&gt;.distribution</td>
<td>Value of the outcome probability distribution for this class.</td>
</tr>
</tbody>
</table>

Data type: String

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.includedClasses.&lt;class name&gt;.statistics</td>
<td>List of objects providing training statistics data. For more information, see Configuring target metrics.</td>
</tr>
</tbody>
</table>

```
[
  {
    "precision": "String",
    "coverage": "String",
    "recall": "String",
    "selected": "String"
  }
]
```

Data type: Array

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.includedClasses.&lt;class name&gt;.statistics.precision</td>
<td>Estimated solution precision metric for this class.</td>
</tr>
</tbody>
</table>

Data type: String (numerical value)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.includedClasses.&lt;class name&gt;.statistics.coverage</td>
<td>Estimated solution coverage metric for this class.</td>
</tr>
</tbody>
</table>

Data type: String (numerical value)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.includedClasses.&lt;class name&gt;.statistics.recall</td>
<td>Estimated solution recall metric for this class.</td>
</tr>
</tbody>
</table>

Data type: String (numerical value)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.includedClasses.&lt;class name&gt;.statistics.selected</td>
<td>Flag that indicates whether this class contains records included in solution training.</td>
</tr>
</tbody>
</table>

Valid values:
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• true: This class contains records selected for training the solution.</td>
</tr>
<tr>
<td></td>
<td>• false: This class is excluded from training.</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td></td>
<td>Data type: String (Boolean value)</td>
</tr>
</tbody>
</table>

`<Object>.excludedClasses`  
Distribution and row count of all the classes excluded from training.

```json
"excludedClasses": {
  "<class name>": {
    "distribution": "0.11",
    "rowCount": "9"
  }
}
```

Data type: Object.

`<Object>.excludedClasses.<class name>.distribution`  
Value of the outcome probability distribution for this class.

Data type: String

`<Object>.excludedClasses.<class name>.rowCount`  
Number of rows excluded from training.

Data type: String (numerical value)

The following example shows how to get training statistics from the active solution.

```javascript
// Get training stats
var mlSolution = sn_ml.ClassificationSolutionStore.get('ml_incident_categorization');

gs.print(JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getTrainingStatistics()), null, 2));
```

Output:

```json
{
  "includedClasses": {
    "Approvals": {
      "distribution": "0.43",
      "statistics": [
      
    }
```
ClassificationSolutionVersion - getVersionNumber()

Gets the version number of a solution object.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Version number.</td>
</tr>
</tbody>
</table>

The following example shows how to get a version number.

```javascript
// Get version number
var mlSolution = sn_ml.ClassificationSolutionStore.get('ml_incident_categorization');

gs.print("Version number: "+JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getVersionNumber()), null, 2));
```

Output:

Version number: 1

`ClassificationSolutionVersion - predict(Object input, Object options)`

Gets the input data for a prediction.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>Object</td>
<td>GlideRecord or array of JSON objects containing field names and values as key-value pairs.</td>
</tr>
<tr>
<td>options</td>
<td>Object</td>
<td>Optional values for filtering prediction results.</td>
</tr>
<tr>
<td>options.apply_threshold</td>
<td></td>
<td>Flag that indicates whether to check the threshold value for the solution and apply it to the result set. Valid values:</td>
</tr>
</tbody>
</table>

## Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>• true: Return results in which confidence is greater than threshold.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Return all results.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: True</td>
</tr>
<tr>
<td>options.top_nNumber</td>
<td>Number</td>
<td>If provided, returns the top results, up to the specified number of predictions.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>JSON object containing the prediction results sorted by sys_id or record_number.</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>&lt;identifier&gt;: [Array]</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td>&lt;Object&gt;.&lt;identifier&gt;</td>
<td>List of objects with details for each prediction result.</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>&lt;identifier&gt;: [</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;confidence&quot;: Number,</td>
</tr>
<tr>
<td></td>
<td>&quot;predictedSysId&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;predictedValue&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;threshold&quot;: Number</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td>&lt;Object&gt;.&lt;identifier&gt;</td>
<td>Value of the confidence associated with the prediction. For example, 53.84.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>&lt;Object&gt;.&lt;identifier&gt;</td>
<td>The sys_id of the predicted sys_id. Results can be from any table on which information is being predicted.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.&lt;identifier&gt;</td>
<td>Value representing the predicted value.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
</tbody>
</table>
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type: String</td>
<td>&lt;Object&gt;.&lt;identifier&gt;.&lt;object&gt;.threshold</td>
</tr>
<tr>
<td>Value of the configured threshold associated with the prediction.</td>
<td></td>
</tr>
<tr>
<td>Data type: Number</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to display prediction results for a `predict()` method that takes a GlideRecord by `sys_id` for input and includes optional parameters to restrict to top three results and exclude the threshold value.

```javascript
var mlSolution = sn_ml.ClassificationSolutionStore.get('ml_incident_categorization');

// single GlideRecord input
define input = new GlideRecord("incident");
input.get("<sys_id>");

// configure optional parameters
var options = {};
options.top_n = 3;
options.apply_threshold = false;

var results = mlSolution.getVersion(1).predict(input, options);
// pretty print JSON results
gs.print(JSON.stringify(JSON.parse(results), null, 2));
```

**Output:**

```json
{
  "<sys_id/gr>": [
    {
      "confidence": 62.10782320780268,
      "threshold": 20.36,
      "predictedValue": "Clone Issues",
      "predictedSysId": ""
    },
    {
      "confidence": 6.945237375770391,
      "threshold": 16.63,
      "predictedValue": "Instance Administration",
      "predictedSysId": ""
    }
  ]
}
```
The following example shows how to display prediction results for a `predict()` method that takes an array of field names as key-value pairs for input and includes optional parameters to restrict to top three results and exclude the threshold value.

```javascript
var mlSolution = sn_ml.ClassificationSolutionStore.get('ml_incident_categorization');

// key-value pairs input
var input = ["short_description":"my email is not working"], {short_description:"need help with password"}];

// configure optional parameters
var options = {
  top_n: 3,
  apply_threshold: false
};

var results = mlSolution.predict(input, options);

// pretty print JSON results
gs.print(JSON.stringify(JSON.parse(results), null, 2));
```

Output:

```json
{
  "i": [
    {
      "confidence": 37.5023032262591,
      "threshold": 10.72,
      "predictedValue": "Authentication",
      "predictedSysId": ""
    },
    {
      "confidence": 24.439964862166583,
      "threshold": 23.7,
      "predictedValue": "Administration",
      "predictedSysId": ""
    }
  ]
}
```
ClassificationSolutionVersion - setPredictionSettings(Object options)

Sets precision, coverage, or recall values at solution level or class level.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Object</td>
<td>Metric configuration values. For information about these features, see Configuring target metrics.</td>
</tr>
</tbody>
</table>

```
{  
  "confidence": 11.736320486031047,
  "threshold": 100,
  "predictedValue": "Security",
  "predictedSysId": ""
}  
},  
"2": [  
{  
  "confidence": 99,
  "threshold": 17.77,
  "predictedValue": "Email",
  "predictedSysId": ""
  
},  
{  
  "confidence": 3.182137005157543,
  "threshold": 10.72,
  "predictedValue": "Authentication",
  "predictedSysId": ""
  
},  
{  
  "confidence": 2.8773826570713514,
  "threshold": -1,
  "predictedValue": "Email (I/f)",
  "predictedSysId": ""
  
}  
]  
}
```
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options.metricName</td>
<td>String</td>
<td>Name of the metric to set. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• precision</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• coverage</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• recall</td>
</tr>
<tr>
<td>options.metricValue</td>
<td>String</td>
<td>Numeric value to assign to the metric.</td>
</tr>
<tr>
<td>options.className</td>
<td>String</td>
<td>Optional. Name of the class to restrict results to. Use the getTrainingStatistics() method to retrieve a complete list of classes for a solution.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set a precision metric to 89.5 for a class named Clone Issues.

```javascript
var mlSolution = 
    sn_ml.ClassificationSolutionStore.get('ml_x_snc_global_global_classification');
var input = {
    "metricName" : "precision", 
    "metricValue" : "89.5", 
    "className" : "Clone Issues"
};
mlSolution.getActiveVersion().setTrainingStatistics(input);
```

**ClassificationSolution - Global**

Scriptable object used in Predictive Intelligence stores.

The ClassificationSolution API requires the Predictive Intelligence plugin (com.glide.platform_ml) and is provided within the sn_ml namespace.

The solution setup-to-training flow is as follows:

1. Create a dataset using the DatasetDefinition API.
2. Optional. Build an encoder using the Encoder API.
3. Use the constructor to create a classification solution object.
4. Add the solution object to the classification solution store using the `ClassificationSolutionStore - add()` method.

5. Train the solution using the `submitTrainingJob()` method. This creates a version of the object that you can manage using the `ClassificationSolutionVersion` API.

⚠ **Note:** This API runs with full privileges. To restrict user access, include an access control mechanism in the script.

For usage guidelines, refer to Using ML APIs.

**ClassificationSolution - ClassificationSolution(Object config)**

Creates a classification solution.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config</td>
<td>Object</td>
<td>JavaScript object containing configuration properties of the solution.</td>
</tr>
<tr>
<td>config.algorithmConfig</td>
<td>Object</td>
<td>JavaScript object containing algorithm configuration properties.</td>
</tr>
</tbody>
</table>

Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| config.algorithmConfig.algorithm | String        | Method for encoding your solution. Possible values:  
- **xgboost**: XGBoost encoding to optimize the training.  
- **logisticRegression**: Method using the logistic regression model for categorical targets such as nominal or ordinal. |
| config.algorithmConfig.targetClassRecall | String        | Applies a class recall parameter to steer a solution's training to bias a specific class. Format is 
"<ClassName:RecallValue>"  
where the recall value is a number between 0 and 100 representing a percentage.  
For example, to set and apply this solution parameter to 90% accuracy for all records you train in the Email class, the value is set to "Email:90". |
| config.dataset               | Object        | DatasetDefinition name.                                                                                                                      |
| config.domainName            | String        | Optional. Domain name associated with this dataset. See Domain separation and Predictive Intelligence.  
Default: Current domain, for example, "global". |
| config.encoder               | Object        | Optional. Trained encoder object to assign to this solution. See Encoder - Encoder(Object config).  

Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config.groupByFieldName</td>
<td>String</td>
<td>Optional. Field name by which the system groups records to build classification solutions. For usage information, see Using group by for classification.</td>
</tr>
<tr>
<td>config.inputFieldNames</td>
<td>Array</td>
<td>List of input field names as strings. The model uses these fields used to make predictions.</td>
</tr>
<tr>
<td>config.label</td>
<td>String</td>
<td>Identifies the prediction task.</td>
</tr>
<tr>
<td>config.minRowCount</td>
<td>String</td>
<td>Optional. Minimum number of records required in the dataset for training. Default: 10000</td>
</tr>
<tr>
<td>config.predictedFieldName</td>
<td>String</td>
<td>Identifies a field to be trained for predictability.</td>
</tr>
<tr>
<td>config.processingLanguage</td>
<td>String</td>
<td>Optional. Processing language in two-letter ISO 639-1 language code format. Default: &quot;en&quot;</td>
</tr>
<tr>
<td>config.stopwords</td>
<td>Array</td>
<td>Optional. Preset list of strings that the system automatically generates based on the language property setting. For details, see Create a custom stopwords list. Default: English Stopwords</td>
</tr>
<tr>
<td>config.trainingFrequency</td>
<td>String</td>
<td>The frequency to retrain the model. Possible values: every_30_days, every_60_days, every_90_days</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• every_120_days</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• every_180_days</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• run_once</td>
<td></td>
<td>Default: run_once</td>
</tr>
</tbody>
</table>

The following example shows how to create an object and add it to the ClassificationSolution store.

```javascript
var myData = new sn_ml.DatasetDefinition(
    {
        'tableName': 'incident',
        'fieldNames': ['category', 'short_description', 'priority'],
        'fieldDetails': [
            {
                'name': 'category',
                'type': 'nominal'
            },
            {
                'name': 'short_description',
                'type': 'text'
            }
        ],
        'encodedQuery': 'activeANYTHING'
    });

var mySolution = new sn_ml.ClassificationSolution(
    {
        'label': 'my solution definition',
        'dataset': myData,
        'predictedFieldName': 'category',
        'inputFieldNames': ['short_description']
    });

var myClassificationName = sn_ml.ClassificationSolutionStore.add(mySolution);
```

**ClassificationSolution - cancelTrainingJob()**

Cancels a job for a solution object that has been submitted for training.
The following example shows how to cancel an existing training job.

```javascript
var mySolution =
    sn_ml.ClassificationSolutionStore.get('ml_sn_global_global_classification');
mySolution.cancelTrainingJob();
```

**ClassificationSolution - getActiveVersion()**

Gets the active `ClassificationSolutionVersion` object.

The following example shows how to get an active `ClassificationSolution` version from the store and return its training status.

```javascript
var mlSolution =
    sn_ml.ClassificationSolutionStore.get('ml_x_snc_global_global_classification');

gs.print(JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getStatus()), null, 2));
```

Output:

```json
{
    "state": "solution_complete",
}
ClassificationSolution - getAllVersions()

Gets all versions of a classification solution.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Existing versions of a solution object. See also ClassificationSolutionVersion API.</td>
</tr>
</tbody>
</table>

The following example shows how to get all ClassificationSolution version objects and call the getVersionNumber() and getStatus() solution version methods on them.

```javascript
var mlSolution = 
    sn_ml.ClassificationSolutionStore.get('ml_x_snc_global_global_classification');

var mlSolutionVersions = mlSolution.getAllVersions();

for (i = 0; i < mlSolutionVersions.length; i++) {
    gs.print("Version " + mlSolutionVersions[i].getVersionNumber() + " Status: " + 
        mlSolutionVersions[i].getStatus() + 
    
};
```

Output:

Version 3 Status: 
({"state":"solution_complete","percentComplete":"100","hasJobEnded":"true"})

Version 2 Status: 
({"state":"solution_complete","percentComplete":"100","hasJobEnded":"true"})

Version 1 Status: {"state":"solution_cancelled","percentComplete":"0","hasJobEnded":"true"}
ClassificationSolution - getLatestVersion()

Gets the latest version of a solution.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>ClassificationSolutionVersion object corresponding to the latest version of a ClassificationSolution().</td>
</tr>
</tbody>
</table>

The following example shows how to get the latest version of a solution and return its training status.

```javascript
var mlSolution =
    sn_ml.ClassificationSolutionStore.get('ml_x_snc_global_global_classification');

gs.print(JSON.stringify(JSON.parse(mlSolution.getLatestVersion().getStatus()), null, 2));
```

**Output:**

```javascript
{
  "state": "solution_complete",
  "percentComplete": "100",
  "hasJobEnded": "true"
}
```

ClassificationSolution - getName()

Gets the name of the object to use for interaction with the store.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The following example shows how to update `ClassificationSolution` dataset information and print the name of the object.

```javascript
// Update solution
var myIncidentData = new sn_ml.DatasetDefinition({
    'tableName': 'incident',
    'fieldNames': ['category', 'short_description', 'priority'],
    'encodedQuery': 'activeANYTHING'
});

var eligibleFields = JSON.parse(myIncidentData.getEligibleFields('classification'));

var myClassification = new sn_ml.ClassificationSolution({
    'label': "my classification solution",
    'dataset': myIncidentData,
    'inputFieldNames': eligibleFields['eligibleInputFieldNames'],
    'predictedFieldName': 'category'
});

// update solution
sn_ml.ClassificationSolutionStore.update('ml_x_snc_global_global_my_solution_definition_4',
    myClassification);

// print solution name
gs.print('Solution Name: ' + myClassification.getName());
```

**Output:**

```
Solution Name: ml_x_snc_global_global_my_solution_definition_4
```

### ClassificationSolution - getProperties()

Gets solution object properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Object | Contents of the Dataset and `ClassificationSolution` object details in the `ClassificationSolutionStore`.

```json
{
    "algorithmConfig": {
        "algorithm": "String",
        "targetClassRecall": "String"
    },
    "datasetProperties": (Object),
    "domainName": "String",
    "encoder": (Object),
    "groupByFieldName": "String",
    "inputFieldNames": [Array],
    "label": "String",
    "name": "String",
    "predictedFieldName": "String",
    "processingLanguage": "String",
    "scope": "String",
    "stopwords": [Array],
    "trainingFrequency": "String"
}
```

**<Object>.algorithmConfig**
Method for encoding the solution.
Data type: Object.

**<Object>.algorithmConfig.algorithm**
Name of the encoding algorithm for training the solution.
Possible values:
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>xgboost</strong>: XGBoost encoding to optimize training.</td>
<td></td>
</tr>
<tr>
<td>• <strong>logisticRegression</strong>: Method using the logistic regression model for categorical targets such as nominal or ordinal.</td>
<td></td>
</tr>
</tbody>
</table>

**<Object>.algorithmConfig.targetClassRecall**

Class recall parameter to steer a solution's training to bias a specific class. The recall value is a number between 0 and 100 representing a percentage.

Data type: String.

**<Object>.datasetProperties**

Lists the properties of the `DatasetDefinition()` object associated with the solution.

```
{
    "encodedQuery": "String",
    "fieldDetails": [Array],
    "fieldNames": [Array],
    "tableName": "String"
}
```

Data type: Object.

**<Object>.datasetProperties tableName**

Name of the table for the dataset. For example,

```
"tableName" : "Incident"
```

Data type: String.

**<Object>.datasetProperties fieldNames**

List of field names from the specified table as strings. For
### Returns (continued)

</tbody>
</table>

The following example gets properties of a solution object in the store.

```javascript
var mySolution = sn_ml.ClassificationSolutionStore.get('ml_sn_global_global_classification_solution');

gs.print(JSON.stringify(JSON.parse(mySolution.getProperties()), null, 2));
```

**Output:**

```json
*** Script: {
  "datasetProperties": {
    "tableName": "incident",
    "fieldNames": ["category", "short_description", "priority", "assignment_group.name"],
    "fieldDetails": [{
      "name": "category",
      "type": "nominal"
    }]
  }
}
```
ClassificationSolution - getVersion(String version)

Gets a solution by provided version number.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>String</td>
<td>Existing version number of a solution.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Specified version of the ClassificationSolution() object on which you can call ClassificationSolutionVersion API methods.</td>
</tr>
</tbody>
</table>

The following example shows how to get the training status of a solution by version number.

```javascript
var mlSolution = 
sn_ml.ClassificationSolutionStore.get('ml_x_snc_global_global_classification');
```
gs.print(JSON.stringify(JSON.parse(mlSolution.getVersion('1').getStatus()), null, 2));

Output:

```javascript
{
  "state": "solution_complete",
  "percentComplete": "100",
  "hasJobEnded": "true"
}
```

**ClassificationSolution - setActiveVersion(String version)**

Activates a specified version of a solution in the store.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>String</td>
<td>Name of the <a href="#">ClassificationSolution()</a> object version to activate. Activating this version deactivates any other version.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to activate a solution version in the store.

```javascript
sn_ml.ClassificationSolution.setActiveVersion("ml_incident_categorization");
```

**ClassificationSolution - submitTrainingJob()**

Submits a training job.

⚠️ **Note:** Before running this method, you must first add a solution to the store using the [ClassificationSolutionStore - add()](#) method.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>ClassificationSolutionVersion object corresponding to the ClassificationSolution being trained.</td>
</tr>
</tbody>
</table>

The following example shows how to create a dataset, apply it to a solution, add the solution to a store, and submit the training job.

```javascript
// Create a dataset
var myData = new sn_ml.DatasetDefinition({
    'tableName' : 'incident',
    'fieldNames' : ['assignment_group', 'short_description', 'description'],
    'encodedQuery' : 'activeANYTHING'
});

// Create a solution
var mySolution = new sn_ml.ClassificationSolution({
    'label': "my solution definition",
    'dataset' : myData,
    'predictedFieldName' : 'assignment_group',
    'inputFieldNames': ['short_description']
});

// Add the solution to the store to later be able to retrieve it.
var my_unique_name = sn_ml.ClassificationSolutionStore.add(mySolution);

// Train the solution - this is a long running job
var myClassifierVersion = mySolution.submitTrainingJob();
```

**ClassifierProbes - Global**

Provides a classifier probe launch facility. Encapsulates an array of probe information records, initialized either from a JavaScript array or the XML serialized version.

Use in any server-side script where you need to define a classifier probe launch facility.
**ClassifierProbes - launch()**

Launches the next highest priority classifier from those in the list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if a classifier is launched; otherwise, false.</td>
</tr>
</tbody>
</table>

**ClassifierProbes - launchSupplementary()**

Launches a supplementary probe.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**ClassifierProbes - size()**

Returns the probe length.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The probe length</td>
</tr>
</tbody>
</table>

Client - Scoped, Global

Provides methods to add data to the MetricBase database, to execute transforms on the MetricBase database, and to receive the results of the transforms.

The Client class can be used in scoped and global server scripts. When using the Client class, use the sn_clotho namespace identifier.

This class is part of the MetricBase application.

Scoped Client - Client()

Create an instance of the client class to access the MetricBase database.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var client = new sn_clotho.Client();
```

Scoped Client - deleteSeries(GlideRecord now_GR, String metric)

Remove the data in the MetricBase database associated with the specified metric in the specified GlideRecord. Use this method for removing test data.

Note: This method deletes data from the MetricBase database. There is no recovery mechanism.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>The records whose time series data for the specified metric is to be deleted.</td>
</tr>
<tr>
<td>metric</td>
<td>String</td>
<td>The name of the metric.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var client = new sn_clotho.Client();
// query drones of a specific model
var drones = new GlideRecord("mb_demo_drone");
drones.addQuery("model", "Kingfisher Phantom");
drones.query();
client.deleteSeries(drones, 'mb_demo_mt_speed');
```

Scoped Client - put(Object metricData)

Saves metric data to the MetricBase database.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metricData</td>
<td>Object</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DataBuilder object containing metric data.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Array of DataBuilder objects containing metric data.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var time = new GlideDateTime();
// two different GlideRecord instances and metrics
var dataBuilder = new sn_clotho.DataBuilder(now_GR, 'cpu_percentage');
dataBuilder.add(time, 0.6);
var dataBuilder2 = new sn_clotho.DataBuilder(gr2, 'disk_free_percentage');
dataBuilder2.add(time, 0.2);
new sn_clotho.Client().put([dataBuilder, dataBuilder2]);
```

ClusteringSolution - Global

Scriptable object used in Predictive Intelligence stores.
The ClusteringSolution API requires the Predictive Intelligence plugin (com.glide.platform_ml) and is provided within the sn_ml namespace.

The solution setup-to-training flow is as follows:

1. Create a dataset using the DatasetDefinition API.
2. Mandatory if using the K-means clustering algorithm. Build an encoder using the Encoder API.
3. Use the constructor to create a clustering solution object.
4. Add the solution object to the clustering solution store using the ClusteringSolutionStore - add() method.
5. Train the solution using the submitTrainingJob() method. This creates a version of the object that you can manage using the ClusteringSolutionVersion API.

Note: This API runs with full privileges. To restrict user access, include an access control mechanism in the script.

For usage guidelines, refer to Using ML APIs.

ClusteringSolution - ClusteringSolution(Object config)

Creates a cluster solution.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config</td>
<td>Object</td>
<td>JavaScript object containing configuration properties of the solution.</td>
</tr>
</tbody>
</table>

```json
{
"algorithmConfig": Object,
"clusterConcept": "String",
"clusterConceptFieldNames": [Array],
"dataset": Object,
"domainName": "String",
"encoder": Object,
"groupByFieldName": "String",
"groupUnclusteredRecords": Boolean,
"inputFieldNames": [Array],
"label": "String",
```
## Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>&quot;maxTimeWindowForUpdate&quot;: Number,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;minRecordsPerCluster&quot;: Number,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;minRowCount&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;processingLanguage&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;stopwords&quot;: [Array],</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;trainingFrequency&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;updateFrequency&quot;: &quot;String&quot;</td>
</tr>
</tbody>
</table>

**config.algorithmConfig**

Object

Required unless setting the encoder property. JavaScript object containing algorithm configuration properties. Property settings vary by the value set in the algorithm property.

```javascript
'algorithmConfig': { 
  "algorithm": "String", 
  // See algorithmConfig.algorithm setting description for property settings based on algorithm }
```

**config.algorithmConfig.algorithm**

String

Method for encoding your solution. Valid values:

- **dbscan** – Density-Based Spatial Clustering of Applications with Noise (DBSCAN) clustering algorithm. Properties used with this algorithm:
  - **distanceMetric**
  - **epsilon**
  - **minimumNeighbours**
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>hdbscan</em></td>
<td>– Hierarchical Density Based Spatial Clustering of Applications with Noise (HDBSCAN) clustering algorithm. Properties used with this algorithm:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>◦ <em>minimumSamples</em></td>
<td></td>
</tr>
<tr>
<td><em>kmeans</em></td>
<td>– K-means clustering algorithm. Default. The <em>targetCoverage</em> property is used with this algorithm.</td>
<td></td>
</tr>
</tbody>
</table>

Some users prefer DBSCAN because it doesn’t require you to specify the number of clusters in the data before clustering.

Properties for *dbscan*:

```
'algorithConfig': {
    "algorithm": "dbscan",
    "distanceMetric": "String",
    "epsilon": Number,
    "minimumNeighbours": Number
}
```

Properties for *hdbscan*:

```
'algorithConfig': {
    "algorithm": "hdbscan",
    "minimumSamples": Number
}
```

Properties for *kmeans*:

```
'algorithConfig': {
    "algorithm": "kmeans",
    "targetCoverage": Number
}
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>config.algorithmConfig.distanceMetric</code></td>
<td>String</td>
<td>DBSCAN algorithm only. Distance metric to scan for similar data objects. Valid values: <code>levenshteinDistance</code></td>
</tr>
<tr>
<td><code>config.algorithmConfig.epsilon</code></td>
<td>Number</td>
<td>DBSCAN algorithm only. Decimal value between 0 and 1 representing the size of the neighborhood search radius.</td>
</tr>
<tr>
<td><code>config.algorithmConfig.minimumNeighbours</code></td>
<td>Number</td>
<td>DBSCAN algorithm only. Minimum number of neighbors required in a point to be a part of a cluster. For <code>levenshteinDistance</code> the value must be 1 so that no points are excluded from the dataset.</td>
</tr>
<tr>
<td><code>config.algorithmConfig.minimumSamples</code></td>
<td>Number</td>
<td>Minimum number of data samples in a neighborhood required to determine if a point is a core point. Default: None</td>
</tr>
<tr>
<td><code>config.algorithmConfig.targetCoverage</code></td>
<td>Number</td>
<td>K-means algorithm only. Percentile field to filter out records that are less similar to each other.</td>
</tr>
<tr>
<td><code>config.clusterConcept</code></td>
<td>String</td>
<td>Optional. Concept type. A concept is a set of words listed in descending order of frequency. To generate a TFIDF-based cluster concept, set the value to <code>tfidf</code>. Concept types are listed in the Clustering Definitions [ml_capability_definition_clustering] table.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>config.clusterConceptFieldNames</td>
<td>Array</td>
<td>Optional. List of cluster concept field names. These values are external columns for creating a cluster concept and not used for cluster solution training. If external columns are provided, those columns are only used for the cluster concept and not for clustering solution training. Cluster concept fields are listed in the Clustering Definitions [ml_capability_definition_clustering] table. Default: Input text columns generate the cluster concept</td>
</tr>
<tr>
<td>config.dataset</td>
<td>Object</td>
<td>DatasetDefinition object name.</td>
</tr>
<tr>
<td>config.domainName</td>
<td>String</td>
<td>Optional. Domain name associated with this dataset. See Domain separation and Predictive Intelligence. Default: Current domain, for example, &quot;global&quot;.</td>
</tr>
<tr>
<td>config.encoder</td>
<td>Object</td>
<td>Required unless setting the algorithmConfig property to &quot;levenshteinDistance&quot;. Trained encoder object to assign to this solution. See Encoder - Encoder(Object config).</td>
</tr>
<tr>
<td>config.groupByFieldName</td>
<td>String</td>
<td>Optional. Field name by which the system groups records into one or more clusters.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>In the following setup example, the system groups each type into an individual cluster, rendering 10 clusters.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>groupByFieldName</strong> value is 'category'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>DatasetDefinition</strong> <strong>tableName</strong> value is 'incident'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Incident [incident] table has 10 category types</td>
</tr>
<tr>
<td>config.groupUnclusteredRecord</td>
<td>Boolean</td>
<td>Flag that indicates whether to group unclustered records in results.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Group unclustered records separately in results.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not group unclustered records in results. Unclustered values (-1) display with the rest of the results.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td>config.inputFieldNames</td>
<td>Array</td>
<td>List of input field names as strings. The model uses these fields used to make predictions.</td>
</tr>
<tr>
<td>config.label</td>
<td>String</td>
<td>Identifies the prediction task.</td>
</tr>
<tr>
<td>config.maxTimeWindowForUpdate</td>
<td>Number</td>
<td>Optional. Number of minutes preceding the model update point to look for records. For example, if the value is 15, the system only looks for records created in the preceding 15</td>
</tr>
</tbody>
</table>
## Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config.minRecordsPerCluster</td>
<td>Number</td>
<td>Optional. Minimum number of records to allow in any cluster. The value must be greater than or equal to 2. Default: 2</td>
</tr>
<tr>
<td>config.minRowCount</td>
<td>String</td>
<td>Optional. Minimum number of records required in the dataset for training. Default: 10000</td>
</tr>
<tr>
<td>config.processingLanguage</td>
<td>String</td>
<td>Processing language in two-letter ISO 639-1 language code format.</td>
</tr>
<tr>
<td>config.stopwords</td>
<td>Array</td>
<td>Optional. Preset list of strings that the system automatically generates based on the <code>language</code> property setting. For details, see <a href="#">Create a custom stopwords list</a>. Default: English Stopwords</td>
</tr>
<tr>
<td>config.trainingFrequency</td>
<td>String</td>
<td>The frequency to retrain the model. Possible values: every_30_days, every_60_days, every_90_days, every_120_days, every_180_days, run_once. Default: run_once</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config.updateFrequency</td>
<td></td>
<td>The frequency at which the model for the solution definition must be rebuilt.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• do_not_update</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• every_1_day</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• every_1_hour</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• every_6_hours</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• every_12_hours</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• every_1_minute</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• every_15_minutes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• every_30_minutes</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: do_not_update</td>
</tr>
</tbody>
</table>

The following example shows how to create an object and add it to the ClusteringSolution store. The example also shows how to submit the object for training.

```javascript
try{
  try{
    var myData = new sn_ml.DatasetDefinition({
      'tableName' : 'incident',
      'fieldNames' : ['category', 'short_description', 'state', 'description'],
      'encodedQuery' : 'activeANYTHING'
    });

    // get a trained encoder from the store
    var myEncoder = sn_ml.EncoderStore.get('<encoder_name >');

    var mySolution = new sn_ml.ClusteringSolution({
      'label': "clustering solution",
      'dataset' : myData,
      'encoder' : myEncoder,
      'inputFieldNames':["short_description"],
      'groupByFieldName' : 'category',
      'algorithmConfig' : {
        'algorithm' : 'kmeans',
      }
    });
  }
}
```
'targetCoverage' : '90'
});

// add solution
var solutionName = sn_ml.ClusteringSolutionStore.add(mySolution);
var solutionVersion = mySolution.submitTrainingJob();
var trainingStatus = solutionVersion.getStatus();
gs.print(JSON.stringify(JSON.parse(trainingStatus), null, 2));
} catch(ex){
    gs.print('Exception caught: ' + ex.getMessage());
}

Output:
{
    "state": "waiting_for_training",
    "percentComplete": "0",
    "hasJobEnded": "false"
}

The following example shows how to include the 'description' field as a cluster concept field.

var myIncidentData = new sn_ml.DatasetDefinition({
    'tableName' : 'incident',
    'fieldNames' : ['category', 'short_description', 'description'],
});

var encodersolutionName = sn_ml.EncoderStore.get('<encoder_name >');

var mySolution = new sn_ml.ClusteringSolution({
    'label': 'clustering_test',
    'dataset': myIncidentData,
    'inputFieldNames': ['short_description'],
    'encoder': encodersolutionName,
    'clusterConceptFieldNames': ['description']
});

var solutionNameFromStore = sn_ml.ClusteringSolutionStore.add(mySolution);
var myClassifier = mySolution.submitTrainingJob();

**ClusteringSolution - cancelTrainingJob()**

Cancels a job for a solution object that has been submitted for training.
The following example shows how to cancel an existing training job.

```javascript
var mySolution = sn_ml.ClusteringSolutionStore.get('ml_sn_global_global_clustering');
mySolution.cancelTrainingJob();
```

**ClusteringSolution - getActiveVersion()**

Gets the active ClusteringSolutionVersion object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to get an active ClusteringSolution version from the store and return its training status.

```javascript
var mlSolution = sn_ml.ClusteringSolutionStore.get('ml_x_snc_global_global_clustering');
gs.print(JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getStatus()), null, 2));
```

**Output:**

```json
{
    "state": "solution_complete",
    "percentComplete": "100",
}
ClusteringSolution - getAllVersions()

Gets all versions of a clustering solution.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Existing versions of a solution object. See also ClusteringSolutionVersion API.</td>
</tr>
</tbody>
</table>

The following example shows how to get all ClusteringSolution version objects and call the getVersionNumber() and getStatus() solution version methods on them.

```javascript
var mlSolution = sn_ml.ClusteringSolutionStore.get('ml_x_snc_global_global_clustering');
var mlSolutionVersions = mlSolution.getAllVersions();
for (i = 0; i < mlSolutionVersions.length; i++) {
    gs.print("Version "+ mlSolutionVersions[i].getVersionNumber() + " Status: "+
    mlSolutionVersions[i].getStatus() +"\n");
};
```

**Output:**

Version 3 Status:
{"state":"solution_complete","percentComplete":"100","hasJobEnded":"true"}

Version 2 Status:
{"state":"solution_complete","percentComplete":"100","hasJobEnded":"true"}

Version 1 Status: 
{"state":"solution_cancelled","percentComplete":"0","hasJobEnded":"true"}

ClusteringSolution - getLatestVersion()

Gets the latest version of a solution.
The following example shows how to get the latest version of a solution and return its training status.

```javascript
var mlSolution = sn_ml.ClusteringSolutionStore.get('ml_x_snc_global_global_clustering');
gs.print(JSON.stringify(JSON.parse(mlSolution.getLatestVersion().getStatus()), null, 2));
```

Output:

```
{
    "state": "solution_complete",
    "percentComplete": "100",
    "hasJobEnded": "true"
}
```

**ClusteringSolution - getName()**

Gets the name of the object to use for interaction with the store.

The following example shows how to update ClusteringSolution dataset information and print the name of the object.
// Update solution
var myIncidentData = new sn_ml.DatasetDefinition({
    'tableName': 'incident',
    'fieldNames': ['category', 'short_description', 'priority'],
    'encodedQuery': 'activeANYTHING'
});

var eligibleFields = JSON.parse(myIncidentData.getEligibleFields('clustering'));

var myCluster = new sn_ml.ClusteringSolution({
    'label': "my clustering solution",
    'dataset': myIncidentData,
    'inputFieldNames': eligibleFields['eligibleInputFieldNames'],
    'predictedFieldName': 'category'
});

// update solution
sn_ml.ClusteringSolutionStore.update('ml_x_snc_global_global_clustering_solution', myCluster);

// print solution name
gs.print('Solution Name: ' + myCluster.getName());

Output:
Solution Name: ml_x_snc_global_global_clustering_solution

**ClusteringSolution - getProperties()**

Gets solution object properties.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Contents of the Dataset and ClusteringSolution() object details in the ClusteringSolutionStore</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>

</thead>
</table>
| `<Object>.datasetProperties.fieldNames` | List of field names from the specified table as strings. For example, 
"fieldNames":
["short_description", "priority"].
Data type: Array. |
| `<Object>.datasetProperties.fieldNames.fieldDetails` | List of JavaScript objects that specify field properties.

```javascript
[
  {
    "name": "String",
    "type": "String"
  }
]
```
Data type: Array. |
| `<Object>.datasetProperties.fieldNames.fieldDetails.<object>.name` | Name of the field defining the type of information to restrict this dataset to.
Data type: String. |
| `<Object>.datasetProperties.fieldDetails.<object>.type` | Machine-learning field type.
Data type: String. |
| `<Object>.datasetProperties.fieldDetails.encodedQuery` | Encoded query string in standard Glide format. See Encoded query strings.
Data type: String. |
| `<Object>.domainName` | Domain name associated with this dataset. See Domain |
## Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;Object&gt;.encoderProperties</code></td>
<td>Encoder object assigned to this solution. See Encoder - Encoder(Object config). Data type: Object.</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.groupByFieldName</code></td>
<td>Field name by which the system groups records into one or more clusters. Data type: String</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.inputFieldNames</code></td>
<td>List of input field names as strings. The model uses these fields used to make predictions. Data type: String</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.label</code></td>
<td>Identifies the prediction task. Data type: String.</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.minRecordsPerCluster</code></td>
<td>Minimum number of records to allow in any cluster. Data type: Number.</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.name</code></td>
<td>System-assigned name. Data type: String.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.predictedFieldName</code></td>
<td>Identifies a field to be trained for predictability. Data type: String.</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.processingLanguage</code></td>
<td>Processing language in two-letter ISO 639-1 language code format. Data type: String.</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.scope</code></td>
<td>Object scope. Currently the only valid value is <code>global</code>. Data type: String.</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.stopwords</code></td>
<td>Optional. Preset list of strings that the system automatically generates based on the <code>language</code> property setting. For details, see Create a custom stopwords list. Data type: Array.</td>
</tr>
</tbody>
</table>
| `<Object>.trainingFrequency` | The frequency to retrain the model. Possible values:  
  - `every_30_days`  
  - `every_60_days`  
  - `every_90_days`  
  - `every_120_days`  
  - `every_180_days`  
  - `run_once`  
  Default: `run_once`  
 Data type: String. |
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;Object&gt;.updateFrequency</code></td>
<td>The frequency at which the model for the solution definition must be rebuilt. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• do_not_update</td>
</tr>
<tr>
<td></td>
<td>• every_1_day</td>
</tr>
<tr>
<td></td>
<td>• every_1_hour</td>
</tr>
<tr>
<td></td>
<td>• every_6_hours</td>
</tr>
<tr>
<td></td>
<td>• every_12_hours</td>
</tr>
<tr>
<td></td>
<td>• every_1_minute</td>
</tr>
<tr>
<td></td>
<td>• every_15_minutes</td>
</tr>
<tr>
<td></td>
<td>• every_30_minutes</td>
</tr>
<tr>
<td></td>
<td>Default: do_not_update</td>
</tr>
<tr>
<td></td>
<td>Datatype: String</td>
</tr>
</tbody>
</table>

The following example gets properties of a solution object in the store.

```javascript
var myCluster = new sn_ml.ClusteringSolutionStore.get("ml_x_snc_global_global_clustering_solution");
gs.print(JSON.stringify(JSON.parse(myCluster.getProperties()), null, 2));
```

**Output:**

```json
*** Script: {
  "algorithmConfig": {
    "algorithm": "kmeans",
    "targetCoverage": "90"
  },
  "datasetProperties": {
    "tableName": "incident",
    "fieldNames": [
      "category",
      "short_description"
    ]
}
```
"state",
"description"
],
"encodedQuery": "activeANYTHING"
],
"domainName": "global",
"encoderProperties": {
"datasetsProperties": [
{
"tableName": "incident",
"fieldNames": [
"assignment_group",
"short_description",
"description"
],
"encodedQuery": "activeANYTHING"
}
],
"domainName": "global",
"label": "my encoder definition",
"name": "ml_x_snc_global_global_my_encoder_definition",
"processingLanguage": "en",

"Default English Stopwords"
],
"trainingFrequency": "run_once",
"updateFrequency": "do_not_update"}
}
ClusteringSolution - getVersion(String version)

Gets a solution by provided version number.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>String</td>
<td>Existing version number of a solution.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Specified version of the ClusteringSolution() object on which you can call ClusteringSolutionVersion API methods.</td>
</tr>
</tbody>
</table>

The following example shows how to get the training status of a solution by version number.

```javascript
var mlSolution = sn_ml.ClusteringSolutionStore.get('ml_x_snc_global_global_clustering');
gs.print(JSON.stringify(JSON.parse(mlSolution.getVersion('1').getStatus()), null, 2));
```

Output:

```json
{
  "state": "solution_complete",
  "percentComplete": "100",
  "hasJobEnded": "true"
}
```

ClusteringSolution - setActiveVersion(String version)

Activates a specified version of a solution in the store.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>String</td>
<td>Name of the ClusteringSolution() object version to activate. Activating this version deactivates any other version.</td>
</tr>
</tbody>
</table>
The following example shows how to activate a solution version in the store.

```javascript
sn_ml.ClusteringSolution.setActiveVersion("ml_incident_categorization");
```

**ClusteringSolution - submitTrainingJob()**

Submits a training job.

**Note:** Before running this method, you must first add a solution to the store using the `ClusteringSolutionStore - add()` method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td><code>ClusteringSolutionVersion</code> object corresponding to the <code>ClusteringSolution</code> being trained.</td>
</tr>
</tbody>
</table>

The following example shows how to create a dataset, apply it to a solution, add the solution to a store, and submit the training job.

```javascript
// Create a dataset
var myData = new sn_ml.DatasetDefinition({
  'tableName': 'incident',
  'fieldNames': ['assignment_group', 'short_description', 'description'],
  'encodedQuery': 'activeANYTHING'
});

// get a trained encoder from the store
var myEncoder = sn_ml.EncoderStore.get('ml_x_snc_global_global_encoder');

// Create a solution
```
```javascript
var mySolution = new sn_ml.ClusteringSolution(

  'label': "my solution definition",
  'dataset': myData,
  'encoder': myEncoder,
  'predictedFieldName': 'assignment_group',
  'inputFieldNames': ['short_description']

);

// Add the solution to the store to later be able to retrieve it.
var my_unique_name = sn_ml.ClusteringSolutionStore.add(mySolution);

// Train the solution - this is a long running job
var myClusterVersion = mySolution.submitTrainingJob();
```

---

**ClusteringSolutionStore - Global**

Enables storing and retrieving solutions.

The ClusteringSolutionStore API requires the Predictive Intelligence plugin (com.glide.platform_ml) and is provided within the sn_ml namespace.

**ClusteringSolutionStore - add(Object mlSolution)**

Adds a new solution object to the store and returns a unique name.

⚠️ **Note:** Label values do not need to be unique. For example, if you run this method with the same label 10 times, this method adds 10 different uniquely-named objects to the store.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mlSolution</td>
<td>ClusteringSolution()</td>
<td>object to add to the store.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>System-generated solution name.</td>
</tr>
</tbody>
</table>
The following example shows how to add a solution to the store. Use `ClusteringSolution - submitTrainingJob()` to run the training job after adding it to the store.

```javascript
// Create a dataset
var myData = new sn_ml.DatasetDefinition({
    'tableName': 'incident',
    'fieldNames': ['assignment_group', 'short_description', 'description'],
    'encodedQuery': 'activeANYTHING'
});

// get a trained encoder from the store
var myEncoder = sn_ml.EncoderStore.get('ml_x_snc_global_global_encoder');

// Create a solution
var mySolution = new sn_ml.ClusteringSolution({
    'label': 'my solution definition',
    'dataset': myData,
    'encoder': myEncoder,
    'predictedFieldName': 'assignment_group',
    'inputFieldNames': ['short_description']
});

// Add the solution to the store to later be able to retrieve it.
var my_unique_name = sn_ml.ClusteringSolutionStore.add(mySolution);
```

**ClusteringSolutionStore - deleteObject(String name)**

Removes a specified solution object from the store.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the ClusteringSolution() object to be deleted.</td>
</tr>
</tbody>
</table>
The following example shows how to delete a solution from the store.

```java
sn_ml.ClusteringSolutionStore.deleteObject("ml_sn_global_global_solution");
```

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**ClusteringSolutionStore - get(String name)**

Gets a solution object from the store.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of a solution in the store.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>ClusteringSolution object. Returns an error if the object does not exist.</td>
</tr>
</tbody>
</table>

The following example shows how to get a solution object from the store using the `get()` method and view its training status using the `ClusteringSolution - getActiveVersion()` and `ClusteringSolutionVersion - getStatus()` methods.

```java
// Get status
var mlSolution = sn_ml.ClusteringSolutionStore.get('ml_incident_categorization');

gs.print(JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getStatus(), null, 2)));  
```

**Output:**

```json
{
  "state":"solution_complete",
  "percentComplete":"100",
  "hasJobEnded":"true"
}
```

**ClusteringSolutionStore - getAllNames(Object options)**

Gets the names of all solution definition records in the store.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Object</td>
<td>Options for restricting results within the specified properties.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;label&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;domainName&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;scope&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>};</td>
</tr>
<tr>
<td>options.label</td>
<td>String</td>
<td>Optional. Label of your solution object.</td>
</tr>
<tr>
<td>options.domainName</td>
<td>String</td>
<td>Optional. Name of the domain for your solution object. Refer to Domain separation and Predictive Intelligence.</td>
</tr>
<tr>
<td>options.scope</td>
<td>String</td>
<td>Optional. Name of an application scope for your solution object.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>List of strings representing solution object names in the store.</td>
</tr>
</tbody>
</table>

In the following example, the `getAllNames()` method returns a list of all names in the store.

```javascript
gs.print(JSON.stringify(JSON.parse(sn_ml.ClusteringSolutionStore.getAllNames()), null, 2));
```

Output:

```
[
  "ml_x_snc_global_global_clustering_solution_1",
  "ml_x_snc_global_global_clustering_solution"
]
```

In the following example, the `getAllNames()` method returns only names associated with values set in the `options` parameter.

```javascript
var options = {
  'label' : 'my solution definition',
  'domainName' : 'global',
};
```
'scope' : 'global' 
};

var solNames = sn_ml.ClusteringSolutionStore.getAllNames(options);
gs.print(JSON.stringify(JSON.parse(solNames), null, 2));

Output:

```javascript
[
  "ml_x_snc_global_global_my_solution_definition"
]
```

**ClusteringSolutionStore - update(String name, Object mlSolution)**

Replaces an existing object in the store with the object passed as a parameter. The object name provided must be empty or match.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the solution to update.</td>
</tr>
<tr>
<td>mlSolution</td>
<td>ClusteringSolution()</td>
<td>object properties to update.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to update a solution object in the store.

```javascript
var solutionUpdate = new sn_ml.ClusteringSolution({
  'label': 'my solution definition',
  'dataset': myData,
  'predictedFieldName': 'assignment_group',
  'inputFieldNames': ['short_description']
});

sn_ml.ClusteringSolutionStore.update('ml_sn_global_global_incident_service',
  solutionUpdate);
```

**ClusteringSolutionVersion - Global**

Scriptable object used in Predictive Intelligence stores.
The ClusteringSolutionVersion API requires the Predictive Intelligence plugin (com.glide.platform_ml) and is provided within the sn_ml namespace.

This API is used for working with solution versions based on ClusteringSolution API objects in the ClusteringSolution store.

The system creates a solution version each time you train a solution definition. Most versions are created during scheduled solution training.

Methods in this API are accessible using the following ClusteringSolution methods:

- `getActiveVersion()`
- `getAllVersions()`
- `getLatestVersion()`
- `getVersion()`

ClusteringSolutionVersion - `cancelUpdateJob()`
Cancels an update job on a trainer.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

The following example shows how to cancel an active training job that has been submitted using the `submitTrainingJob()` method.

```javascript
var myCluster = new sn_ml.ClusteringSolutionStore.get("ml_x_snc_global_global_clustering_solution");
var mlSolutionVersion = myCluster.getActiveVersion();
mlSolutionVersion.cancelUpdateJob();
```

ClusteringSolutionVersion - `deleteClusterAssignments(Object options)`
Deletes cluster assignments from rows by position in table sequence or GlideDateTime.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Object</td>
<td>Object defining one option for deleting cluster assignments.</td>
</tr>
<tr>
<td>Note:</td>
<td></td>
<td>Only one delete option is valid.</td>
</tr>
<tr>
<td>options.updatedUntil</td>
<td>String</td>
<td>Deletes rows for clusters with updated_since values occurring before this value. Format must be provided as GlideDateTime.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{ &quot;updatedUntil&quot; : &quot;String&quot; }</td>
</tr>
<tr>
<td>options.sequenceUntil</td>
<td>String</td>
<td>Deletes rows for clusters with insert_sequence values occurring before this value in the ML Cluster Detail [ml_cluster_detail] table. The sequence position starting point value is 1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{ &quot;sequenceUntil&quot; : Number }</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of rows deleted from the ML Cluster Detail [ml_cluster_detail] table.</td>
</tr>
</tbody>
</table>

The following example shows how to delete rows for clusters with updated_since time preceding '2020-06-28 02:50:53'.

```javascript
var mlSolution =
    sn_ml.ClusteringSolutionStore.get("ml_x_snc_global_global_clustering_solution");

var mlSolutionVersion = mlSolution.getActiveVersion();

var options = {};
options.updatedUntil = '2020-06-28 02:50:53';

var results = mlSolutionVersion.deleteClusterAssignments(options);

gs.print("Number of deleted rows: "+results);
```

**Output:**

Number of deleted rows: 6417
The following example shows how to delete rows for clusters with updated_since that are sequentially positioned prior to 1000.

```javascript
var mlSolution = sn_ml.ClusteringSolutionStore.get("ml_x_snc_global_global_clustering_solution");

var mlSolutionVersion = mlSolution.getActiveVersion();

var options = {};
options.sequenceUntil = 1000;

var results = mlSolutionVersion.deleteClusterAssignments(options);

gs.print("Number of deleted rows: "+results);
```

Output:

Number of deleted rows: 999

**ClusteringSolutionVersion - getClusterAssignments(Object options)**

Gets assignments for a clustering solution.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Object</td>
<td>Values to use to narrow down the returned results by group, level, system update times, and table row number within a clustering solution. Minimum of one argument must be specified.</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>options.group_by</td>
<td>String</td>
<td>Optional. Identifies the segmentation field for which to retrieve cluster memberships, for example, assignment_group.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This field provides the same grouping as options provided in the <strong>Use Group By</strong> check box in the <strong>Clustering Definition</strong> form. The information provided varies based on the table selected in the <strong>Table</strong> field. For more information, see Create and train a clustering solution.</td>
</tr>
<tr>
<td>options.limit</td>
<td>Number</td>
<td>Optional. Maximum number of cluster assignments to retrieve.</td>
</tr>
<tr>
<td>options.sequenceSince</td>
<td>Number</td>
<td>Starting position in a table sequence. Returns information for clusters with insert_sequence enabled and positioned after this value in the ML Cluster Detail [ml_cluster_detail] table. The sequence position starting point value is 1.</td>
</tr>
<tr>
<td>options.sequenceUntil</td>
<td>Number</td>
<td>Returns assignments for clusters with insert_sequence values occurring before this value in the ML Cluster Detail [ml_cluster_detail] table. The sequence position starting point value is 1.</td>
</tr>
<tr>
<td>options.topNPerCluster</td>
<td>Number</td>
<td>Number of top results to receive for each cluster.</td>
</tr>
<tr>
<td>options.updatedSince</td>
<td>String</td>
<td>Optional. Date and time. Returns information for clusters with sys_updated_on after the value provided in GlideDateTime.</td>
</tr>
<tr>
<td>options.updatedUntil</td>
<td>String</td>
<td>Optional. Date and time. Returns information for clusters with sys_updated_on before the value provided in GlideDateTime.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>List of objects containing cluster information in increasing order by cluster_id.</td>
</tr>
<tr>
<td></td>
<td>[</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
|               | "cluster_id": "String",
|               | "group_by": "String",
|               | "rec_display_id": "String",
|               | "rec_sys_id": "String"
|
*<object>.cluster_id* Unique cluster number within a solution of clusters.

*<object>.group_by* Grouped, name of the segmentation field associated with this cluster.

*<object>.rec_display_id* Record type and number.

*<object>.rec_sys_id* Record sys_id.

The following example shows how to use the *options* object to filter clustering results.

```javascript
var mlSolution = sn_ml.ClusteringSolutionStore.get("solution_name");

var mlSolutionVersion = mlSolution.getActiveVersion();

var options = {};
options.clusterId = 56;
options.topNPerCluster = 10;
options.updatedUntil = '2020-01-17 23:16:14';
options.updatedSince = '2020-01-17 23:16:13';
options.sequenceUntil = 1000;
options.sequenceSince = 1100;
options.limit = 100;

var results = mlSolutionVersion.getClusterAssignments(options);

gs.print(results);
```

Output:

```javascript
[{
  "cluster_id": "1",
  "rec_display_id": "Incident",
  "INC0014483", "rec_sys_id": "04e33e7adb401300864adfea5e961900", "group_by": "network"},
{
  "cluster_id": "1",
  "rec_display_id": "Incident",
  "INC0011133", "rec_sys_id": "5bd23af2db401300864adfea5e96194d", "group_by": "network"}
]```
ClusteringSolutionVersion - getClusterInfo(Object options)

Gets information for a specified clustering solution in the store. The purity measurement provides insights as a percentage for the clustering fields on which the purity is based.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Object</td>
<td>Optional. Object containing properties that enable filtering results within a clustering solution.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;clusterId&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;groupBy&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;limit&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;recSysId&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;sequenceSince&quot;: Number,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;sequenceUntil&quot;: Number,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;updatedSince&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;updatedUntil&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: Return cluster memberships for all clusters.</td>
</tr>
<tr>
<td>options.groupBy</td>
<td>String</td>
<td>Optional. Identifies the segmentation field for which to retrieve cluster memberships, for example, assignment_group.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This field provides the same grouping as options provided in the <strong>Use Group By</strong> check box in the <strong>Clustering Definition</strong> form. The information provided varies based on the table selected in the <strong>Table</strong> field. For more information, see <a href="#">Create and train a clustering solution</a>.</td>
</tr>
<tr>
<td>options.limit</td>
<td>Number</td>
<td>Optional. Maximum number of cluster assignments to retrieve.</td>
</tr>
<tr>
<td>options.recSysId</td>
<td>String</td>
<td>Optional. Sys_id of a record by which to find cluster information.</td>
</tr>
</tbody>
</table>
| options.sequenceSince | Number| Starting position in a table sequence. Returns information for clusters with insert_sequence
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options.sequenceUntil</td>
<td>String</td>
<td>Optional. Ending position in a table sequence. Returns assignments for clusters with <code>insert_sequence</code> values occurring before this value in the ML Cluster Detail [ml_cluster_detail] table. The sequence position starting point value is 1.</td>
</tr>
<tr>
<td>options.updatedSince</td>
<td>String</td>
<td>Optional. Date and time. Returns information for clusters with <code>sys_updated_on</code> after the value provided in GlideDateTime format.</td>
</tr>
<tr>
<td>options.updatedUntil</td>
<td>String</td>
<td>Optional. Date and time. Returns information for clusters with <code>sys_updated_on</code> before the value provided in GlideDateTime.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>List of objects containing cluster information.</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>

<td>&quot;cluster_size&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;group_by&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;insert_sequence&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;purity&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;sys_updated_on&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>

<object>.cluster_concept

Set of words that describe the cluster in descending order of frequency.
Data type: String

<object>.cluster_id

Unique cluster number within a solution of clusters.
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;object&gt;.cluster_quality</td>
<td>Number from 0 to 100. Higher numbers indicate higher cluster density. Data type: String</td>
</tr>
<tr>
<td>&lt;object&gt;.cluster_size</td>
<td>Number of records in a cluster. Data type: String</td>
</tr>
<tr>
<td>&lt;object&gt;.group_by</td>
<td>If grouped, name of the segmentation field associated with this cluster. Data type: String</td>
</tr>
<tr>
<td>&lt;object&gt;.insert_sequence</td>
<td>Sequential position number of the cluster in the Cluster Summary [ml_cluster_summary] table. Data type: String</td>
</tr>
<tr>
<td>&lt;object&gt;.purity</td>
<td>Percentage value representing the purity of cluster quality.</td>
</tr>
<tr>
<td>&lt;object&gt;.sys_updated_on</td>
<td>System GlideDateTime value representing the date and time at which this cluster was last updated. Data type: String</td>
</tr>
</tbody>
</table>

The following example shows how to set the options object parameter and print the filtered cluster results.

```javascript
var mlSolution = sn_ml.ClusteringSolutionStore.get("ml_x_snc_global_global_clustering_solution");

var mlSolutionVersion = mlSolution.getActiveVersion();

var options = {
  updatedSince: '2020-05-28 02:09:53',
  updatedUntil: '2020-05-28 03:15:00',
  sequenceSince: 1,
  limit: 10,
};

var results = mlSolutionVersion.getClusterInfo(options);

gs.print(JSON.stringify(JSON.parse(results), null, 2));
```

Output:
[  
  {  
    "cluster_id": "1",  
    "cluster_quality": "100",  
    "cluster_size": "17",  
    "purity": "",  
    "insert_sequence": "8",  
    "group_by": "VPN Customer",  
    "sys_updated_on": "2020-05-28 02:09:53",  
    "cluster_concept": "vpn instance connection ldap user log unable usability tunnel"  
  },  
  {

  }  
]

### ClusteringSolutionVersion - getProperties()

Gets solution object properties and version number.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Contents of the Dataset and <strong>Clusteringsolution</strong> version details. Results vary by object property setup.</td>
</tr>
</tbody>
</table>

```
{
    "algorithmConfig": {Object},
    "datasetProperties": {Object},
    "domainName": "String",
    "encoder": {Object},
    "groupByFieldName": "String",
    "inputFieldNames": [Array],
    "isActive": "Boolean",
    "label": "String",
    "minRecordsPerCluster": Number,
    "name": "String",  "processingLanguage": "String",
    "scope": "String",
    "stopwords": [Array],
    "trainingFrequency": "String",
    "updateFrequency": "String",
    "versionNumber": "Number"
}
```

**<Object>.algorithmConfig**

JavaScript object containing algorithm configuration properties. Property results vary by the value set in the **algorithm** property.

```
'algorithimConfig' : {
    "algorithm": "String",
    // See algorithmConfig.algorithm setting description for property settings based on algorithm
}
```

Data type: Object.

**<Object>.algorithmConfig.algorithm**

JavaScript object containing your solution. Properties for **dbscan**:

```
'algorithimConfig': {
    "algorithm": "dbscan",
    "distanceMetric": "String",
    "epsilon": Number,
    "minimumNeighbours": Number
}
```
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Properties for **kmeans:** | 'algorithmConfig': {   
|                       |   "algorithm": "kmeans",  
|                       |   "targetCoverage": Number                                                                                         |
|                       | Data type: String.                                                                                                   |
| <Object>.algorithmConfig.distanceMetric | DBSCAN algorithm only. Distance metric to scan for similar data objects. Data type: String.                       |
| <Object>.algorithmConfig.epsilon | DBSCAN algorithm only. Decimal value between 0 and 1 representing the size of the neighborhood search radius. Data type: Number. |
| <Object>.algorithmConfig.minimumNeighbours | DBSCAN algorithm only. Minimum number of neighbors required in a point to be a part of a cluster. For levenshteinDistance, the value must be 1 so that no points are excluded from the dataset. Data type: Number. |
| <Object>.algorithmConfig.targetCoverage | K-means algorithm only. Percentile field to filter out records that are less similar to each other. Data type: Number. |
| <Object>.datasetProperties | properties of the DatasetDefinition object associated with the solution.                                          |
|                       | {   
|                       |   "encodedQuery": "String",  
|                       |   "fieldDetails": [Array],  
|                       |   "fieldNames": [Array],  
|                       |   "tableName": "String"                                                                                         |
|                       | Data type: Object.                                                                                                   |
| <Object>.datasetProperties.tableName | Name of the table for the dataset. For example, "tableName" : "Incident". Data type: String. |

<td>&lt;Object&gt;.domainName</td>
<td>Domain name associated with this dataset. See Domain separation and Predictive Intelligence. Data type: String.</td>
</tr>
<tr>
<td>Object.encoderProperties</td>
<td>Encoder object assigned to this solution. See Encoder - Encoder(Object config). Data type: Object.</td>
</tr>
<tr>
<td>Object.groupByNameField</td>
<td>Field name by which the system groups records into one or more clusters. Data type: String</td>
</tr>
<tr>
<td>Object.inputFieldNames</td>
<td>List of input field names as strings. The model uses these fields used to make predictions.</td>
</tr>
</tbody>
</table>
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.isActive</td>
<td>Flag that indicates whether this version is active.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Version is active.</td>
</tr>
<tr>
<td></td>
<td>• false: Version is not active.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.label</td>
<td>Identifies the prediction task.</td>

<td>&quot;label&quot;: &quot;my first prediction&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.minRecordsPerCluster</td>
<td>Number of records to allow in any cluster.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>&lt;Object&gt;.name</td>
<td>System-assigned name.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.processingLanguage</td>
<td>Language in two-letter ISO 639-1 language code format.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.scope</td>
<td>Object scope. Currently the only valid value is global.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.stopwords</td>
<td>Optional. Preset list of strings that the system automatically generates</td>
</tr>
<tr>
<td></td>
<td>based on the language property setting.</td>
</tr>
<tr>
<td></td>
<td>For details, see <a href="#">Create a custom stopwords list</a>.</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td>&lt;Object&gt;.trainingFrequency</td>
<td>Frequency to retrain the model.</td>
</tr>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>• every_30_days</td>
</tr>
<tr>
<td></td>
<td>• every_60_days</td>

<tr>
<td></td>
<td>• every_90_days</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------------------------</td>
</tr>
<tr>
<td>every_120_days</td>
<td></td>
</tr>
<tr>
<td>every_180_days</td>
<td></td>
</tr>
<tr>
<td>run_once</td>
<td>Default: run_once</td>
</tr>
</tbody>
</table>

Data type: String.

<Object>.updateFrequency

The frequency at which the model for the solution definition must be rebuilt. Possible values:

- do_not_update
- every_1_day
- every_1_hour
- every_6_hours
- every_12_hours
- every_1_minute
- every_15_minutes
- every_30_minutes

Default: do_not_update

Datatype: String

<Object>.versionNumber

Version number of the ClusteringSolution object.

The following example gets properties of the active object version in the store.

```javascript
// Get properties
var mlSolution = 
    sn_ml.ClusteringSolutionStore.get('ml_x_snc_global_global_clustering_solution');

gs.print(JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getProperties()), null, 2));
```

**Output:**

```json
*** Script: {
    "algorithmConfig": {
```
"algorithm": "kmeans",
"targetCoverage": "90"
},

ClusteringSolutionVersion - getStatus(Boolean includeDetails)

Gets training completion status.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>includeDetails</td>
<td>Boolean</td>
<td>Flag that indicates whether to return status details. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Return additional details.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not return additional details.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: False</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>JavaScript object containing training status information for a ClusteringSolution object.</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;state&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;percentComplete&quot;: &quot;Number as a String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;hasJobEnded&quot;: &quot;Boolean value as a String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;details&quot;: {Object}</td>
</tr>
<tr>
<td>&lt;Object&gt;.state</td>
<td>Training completion state. If the training job reaches a terminal state, the job does not leave that state. If the state is terminal, the hasJobEnded property is set to true. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• fetching_files_for_training</td>
</tr>
<tr>
<td></td>
<td>• preparing_data</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• retry</td>
<td></td>
</tr>
<tr>
<td>• solution_cancelled <em>(terminal)</em></td>
<td></td>
</tr>
<tr>
<td>• solution_complete <em>(terminal)</em></td>
<td></td>
</tr>
<tr>
<td>• solution_error <em>(terminal)</em></td>
<td></td>
</tr>
<tr>
<td>• solution_incomplete</td>
<td></td>
</tr>
<tr>
<td>• training_request_received</td>
<td></td>
</tr>
<tr>
<td>• training_request timed_out <em>(terminal)</em></td>
<td></td>
</tr>
<tr>
<td>• training_solution</td>
<td></td>
</tr>
<tr>
<td>• uploading_solution</td>
<td></td>
</tr>
<tr>
<td>• waiting_for_training</td>
<td></td>
</tr>
</tbody>
</table>

Data type: String

<Object>.hasJobEnded

Flag that indicates whether training is complete.

Valid values:
• true: Training is complete.
• false: Training is incomplete.

Data type: Boolean value as a String

<Object>.percentComplete

Number between zero and 100 representing training percent complete. If the completion percentage is less than 100, the job might be in a terminal state. For example, if training times out.

Data type: Number as a String

<Object>.details

Object containing a list of additional training details.

Data type: Object

The following example shows a successful result with training complete.

```javascript
// Get status
var mlSolution =
    sn_ml.ClusteringSolutionStore.get('ml_x_snc_global_global_cluster_solution');
```
The following example shows an unsuccessful result with training complete.

```
// Get status
var solutionName = 'ml_x_snc_global_global_cluster_solution';
var mlSolution = sn_ml.ClusteringSolutionStore.get(solutionName);
var trainingStatus = mlSolution.getLatestVersion().getStatus();
gs.print(JSON.stringify(JSON.parse(trainingStatus), null, 2));
```

Output:

```
{
  "state":"solution_error",
  "percentComplete":"100",
  "hasJobEnded":"true",
}
```

**ClusteringSolutionVersion - getTopNPurityInfo(Object options)**

Gets the top purity results for a clustering solution. The purity measurement provides insights as a percentage for the clustering fields on which the purity is based.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>options</td>
</tr>
</tbody>
</table>
|          |          | [{
  "clusterIds": [Array],
  "groupBy": [Array],
  "purityFields": [Array],
|          |          |                   |

### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>options.clusterIds</code></td>
<td>Array</td>
<td>Optional. List of cluster IDs provided as strings. A cluster ID is provided in the Cluster Summary [ml_cluster_summary] table. If provided, this method returns purity cluster information for each specified cluster. Default: This method returns purity information for all clusters.</td>
</tr>
<tr>
<td><code>options.groupBy</code></td>
<td>Array</td>
<td>Optional. List of group_by field strings from your table to help the system identify the class which is most frequent in the cluster. If provided, returns purity information for cluster solutions using group_by fields. The Cluster Summary [ml_cluster_summary] table lists clusters and any associated Group by values. This field only applies to clusters that use group by in the clustering definition. Eligible fields are listed in the Table field. For details on the group by feature, refer to Create and train a clustering solution.</td>
</tr>
<tr>
<td><code>options.purityFields</code></td>
<td>Array</td>
<td>Optional. List of purity field strings. If provided, this method only returns information for these purity fields. You can view purity values for a cluster in the Cluster Summary [ml_cluster_summary] table lists. <strong>Note:</strong> If both <code>purity_fields</code> and <code>topN_fields</code> are provided, this method returns <code>topN_fields</code> first, then selects fields from <code>purity_fields</code>. Default: Return purity information for all purity fields saved for the cluster.</td>
</tr>
<tr>
<td><code>options.topN</code></td>
<td>Number</td>
<td>Optional. Restricts the number of predictions to return to the highest values for each purity field. Maximum value: 10</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options.topNFields</td>
<td>Number</td>
<td>Optional. Restricts the number of purity fields returned to fields with the highest purity for each cluster. Maximum value: 10 Default: Return all fields in the cluster.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>JSON-formatted string containing a list of clusters with purity fields and details.</td>
</tr>
</tbody>
</table>

**Note:** Results vary based on settings made in the `options` input parameter.

The following information illustrates how cluster purity results are sorted and categorized. Refer to the example for actual output.

```json
{
    "<clusterID>"[:
        // List sorted by purity per field
        { "<fieldName>"[:
            // List sorted by purity per field value
            {"<field_val1_1>"":"<purity>",
             // Additional field values
             }],
            // Additional fields
         ],
        // Additional clusters
    }
```
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String.&lt;clusterID&gt;.&lt;field&gt; of objects representing purity fields arranged in descending order by purity value per field. The <code>options.top_n_fields</code> input object parameter property determines the number of fields returned.</td>
<td></td>
</tr>
</tbody>
</table>

```
"<field>:{{"<field_val>":"<purity>"}}}
```

Data type: Array

| String.<clusterID>.<field>.<values> of objects containing field value and purity. For example, `{"priority":{{"5":"100"}}}` is a priority field with a score of 5 and a purity value of 100 percent. Results list in descending order by purity percentage. The `options.top_n` input object parameter property determines the number of results returned. |

Data type: Array

The following example shows how to get the top two purity results for the category field in specific cluster solutions.

```javascript
var solution = new GlideRecord('ml_solution');
solution.addQuery('sys_id', '<clustering_solution_sys_id>');
solution.addQuery('active', 'true');
solution.query();

while (solution.next()) {

    var options = {};
    options.clusterIds = ['1', '3', '5'];
    options.purityFields = ['category'];
    options.topN = '2';
    options.topNFields = '2';

    var clustering = new sn_ml.ClusteringSolutionVersion(solution);
    var results = clustering.getTopNPurityInfo(options);

    gs.info(results);
}
```

Output displays purity insights based on the settings provided in the options parameter.
**ClusteringSolutionVersion - getUpdateStatus()**

Gets the status of the most recent clustering solution update job.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>State of the clustering solution update. States:</td>
</tr>
<tr>
<td></td>
<td>• Configuration or network error</td>
</tr>
<tr>
<td></td>
<td>• Error while updating solution</td>
</tr>
<tr>
<td></td>
<td>• Fetching files for updating</td>
</tr>
<tr>
<td></td>
<td>• Preparing data</td>
</tr>
<tr>
<td></td>
<td>• Unauthorized</td>
</tr>
<tr>
<td></td>
<td>• Update complete</td>
</tr>
<tr>
<td></td>
<td>• Updating is cancelled</td>
</tr>
<tr>
<td></td>
<td>• Updating request received</td>
</tr>
<tr>
<td></td>
<td>• Updating request timed out</td>
</tr>
<tr>
<td></td>
<td>• Updating solution</td>
</tr>
<tr>
<td></td>
<td>• Uploading</td>
</tr>
<tr>
<td></td>
<td>• Waiting</td>
</tr>
</tbody>
</table>

The following example shows how to get the update status of a clustering solution.

```javascript
var myCluster = new
  sn_ml.ClusteringSolutionStore.get("ml_x_snc_global_global_clustering_solution");
gs.print(JSON.stringify(myCluster.getActiveVersion().getUpdateStatus()));
```
Output:

"Update Complete"

**ClusteringSolutionVersion - getVersionNumber()**

Gets the version number of a solution object.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Version number.</td>
</tr>
</tbody>
</table>

The following example shows how to get a version number.

```javascript
// Get version number
var mlSolution =
    sn_ml.ClusteringSolutionStore.get('ml_x_snc_global_global_clustering_solution');
gs.print("Version number:
    " + JSON.stringify(JSON.parse(mlSolution.getActiveVersion().getVersionNumber()), null, 2));
```

Output:

Version number: 1

**ClusteringSolutionVersion - predict(Object input, Object options)**

Gets the input data for a prediction.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>input</td>
</tr>
<tr>
<td>options</td>
</tr>
</tbody>
</table>

```javascript
{  
    "apply_threshold": Boolean, 
}
```
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>options.apply_threshold</strong></td>
<td>Boolean</td>
<td>Flag that indicates whether to check the threshold value for the solution and apply it to the result set. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- true: Return results in which confidence is greater than threshold.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- false: Return all results.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: True</td>
</tr>
<tr>
<td><strong>options.top_n</strong></td>
<td>Number</td>
<td>If provided, returns the top results, up to the specified number of predictions.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>JSON object containing the prediction results sorted by sys_id or record_number.</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&lt;identifier&gt;: [Array]</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>&lt;Object&gt;.&lt;identifier&gt;</td>
<td>List of objects with details for each prediction result.</td>
</tr>
<tr>
<td></td>
<td>&lt;identifier&gt;: [</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;confidence&quot;: Number,</td>
</tr>
<tr>
<td></td>
<td>&quot;predictedSysId&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;predictedValue&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;threshold&quot;: Number</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td>&lt;Object&gt;.&lt;identifier&gt;.object</td>
<td>object of the confidence associated with the prediction.</td>
</tr>
<tr>
<td></td>
<td>For example, 53.84.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.&lt;identifier&gt;.&lt;object&gt;.predictedSysId</td>
<td>The sys_id of the predicted value. Results can be from any table on which information is being predicted. Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.&lt;identifier&gt;.&lt;object&gt;.predictedValue</td>
<td>Value representing the prediction result. Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.&lt;identifier&gt;.&lt;object&gt;.threshold</td>
<td>Value of the configured threshold associated with the prediction. Data type: Number</td>
</tr>
</tbody>
</table>

The following example shows how to display prediction results for a `predict()` method that takes a GlideRecord by sys_id for input and includes optional parameters to restrict to top three results and exclude the threshold value.

```javascript
var mlSolution = sn_ml.ClusteringSolutionStore.get('ml_incident_categorization');

// single GlideRecord input
var input = new GlideRecord("incident");
input.get("<sys_id>");

// configure optional parameters
var options = {};
options.top_n = 3;
options.apply_threshold = false;

var results = mlSolution.getVersion(1).predict(input, options);
// pretty print JSON results
gs.print(JSON.stringify(JSON.parse(results), null, 2));
```

```javascript
{
  "<sys_id/gr>": [
    {
      "confidence": 62.10782320780268,
      "threshold": 20.36,
      "predictedValue": "Clone Issues",
      "predictedSysId": ""
    },
    {
      "confidence": 6.945237375770391,
      "threshold": 20.36,
      "predictedValue": "","n
```
The following example shows how to display prediction results for a `predict()` method that takes an array of field names as key-value pairs for input and includes optional parameters to restrict to top three results and exclude the threshold value.

```javascript
var mlSolution = sn_ml.ClusteringSolutionStore.get("ml_incident_categorization");

// key-value pairs input
var input = [{short_description:"my email is not working"}, {short_description:"need help with password"}];

// configure optional parameters
var options = {};
options.top_n = 3;
options.apply_threshold = false;
var results = mlSolution.predict(input, options);

// pretty print JSON results
gs.print(JSON.stringify(JSON.parse(results), null, 2));
```
ClusteringSolutionVersion - submitUpdateJob(Object options)

Submits clustering update jobs with options to narrow results to a specific table and filter for matching records.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Object</td>
<td>JavaScript object containing options on which to base a clustering solution update.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options.filter</td>
<td>String</td>
<td>Encoded query string in standard Glide format. See Encoded query strings. Enables running an update job based on the filter provided.</td>
</tr>
<tr>
<td>options.table</td>
<td>String</td>
<td>Name of the table on which to run an update job.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to submit an update job.

```javascript
var myCluster = new
  sn_ml.ClusteringSolutionStore.get("ml_x_snc_global_global_clustering_solution");

var options = {
  "filter": "precision",
  "table": "incident"
};

myCluster.getActiveVersion().submitUpdateJob(options);
```

**CMDBDuplicateTaskUtils - Global**

Use the CMDBDuplicateTaskUtils API to create a De-duplication task that contains duplicate CIs that are of independent type.

A de-duplication task can only contain CMDB CIs that are not in another de-duplication task.

**CMDBDuplicateTaskUtils - CMDBDuplicateTaskUtils()**

Creates an instance of the CMDBDuplicateTaskUtils class.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### CMDBDuplicateTaskUtils - `createDuplicateTask(String sysIDs)`

Create a **De-duplication** task in which the sys_ids of duplicate tasks are specified.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysIDs</td>
<td>String</td>
<td>A comma separated list of sys_IDs.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The sys_ID of the created task. Returns null if the input string is empty, the input parameter contains a sys_ID that is not in the cmdb_ci table, or the input parameter contains a sys_ID that is in an open de-duplication task.</td>
</tr>
</tbody>
</table>

```java
// where sys-id1 and sys-id2 are sys_IDs of CIs in the cmdb_ci table
var sysIDs = 'sys-id1, sys-id2';
var dupTaskUtil = new CMDBDuplicateTaskUtils();
var deDupTaskID = dupTaskUtil.createDuplicateTask(sysIDs);
gs.info(deDupTaskID);
```

### CMDBGroupAPI - Scoped

The **CMDBGroupAPI** provides methods for performing actions on Configuration Management Database (CMDB) groups.

The **CMDBGroupAPI** is a scoped static class. To use the class you must include the namespace identifier `sn_cmdbgroup` before the CMDBGroupAPI object. For example:

```java
var response = sn_cmdbgroup.CMDBGroupAPI.getManualCIList(groupSysId, false);
```

To access this API you must have the itil or asset role.
CMDBGroupAPI - getAllCI(String groupId, Boolean requireCompleteSet, Boolean requireAllQueryNodesCis)

Returns all configuration items (CIs) for the specified group. The results include all manual CIs and the list of CIs from the query builder's saved query.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupId</td>
<td>String</td>
<td>Sys_id of the Configuration Management Database (CMDB) group.</td>
</tr>
</tbody>
</table>
| requireCompleteSet    | Boolean       | Optional, but must be passed if `requireAllQueryNodesCis` is passed. Flag that indicates whether an empty string is returned if any CIs are filtered out by access control list (ACL) restrictions. Valid values:  
  • true: Return empty string.  
  • false: Don't return value.  
  Default: false |
| requireAllQueryNodesCis| Boolean       | Optional. Flag that indicates whether to return CIs from all CMDB classes of the query. Valid values:  
  • true: Return CIs from all columns.  
  • false: Only return CIs from the starting node of the query builder query.  
  Default: false |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errors</td>
<td>List of errors for a failed operation. Data type: Array</td>
</tr>
</tbody>
</table>

*errors*: [
  
]
## Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errors.error</td>
<td>Error name. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• GROUP_SYS_ID_IS_NOT_FOUND</td>
</tr>
<tr>
<td></td>
<td>• GROUP_SYS_ID_IS_EMPTY</td>
</tr>
<tr>
<td></td>
<td>• FAIL_TO_INSERT_GROUP_CI_PAIR</td>
</tr>
<tr>
<td></td>
<td>• FAIL_TO_INSERT_GROUP_QUERY_ID_PAIR</td>
</tr>
<tr>
<td></td>
<td>• CI_CAN_NOT_FOUND</td>
</tr>
<tr>
<td></td>
<td>• SAVED_QUERY_ID_NOT_FOUND</td>
</tr>
<tr>
<td></td>
<td>• ERROR_DURING_QUERY_BUILDER_PROCESS_QUERY</td>

<tr>
<td></td>
<td>• TIMEOUT_DURING_QUERY_BUILDER_PROCESS_QUERY</td>
</tr>
<tr>
<td></td>
<td>• NOT_COMPLETE_DURING_QUERY_BUILDER_PROCESS_QUERY</td>
</tr>
<tr>
<td></td>
<td>• MAX_LIMIT_DURING_QUERY_BUILDER_PROCESS_QUERY</td>
</tr>
<tr>
<td></td>
<td>• GROUP_API_TIMEOUT</td>
</tr>
<tr>
<td></td>
<td>• EXCEPTION_FROM_EXECUTE_QUERY</td>
</tr>
<tr>
<td></td>
<td>• SOME_CI_NOT_VISIBLE_DUE_TO_SECURITY_CONSTRAINT</td>
</tr>
<tr>
<td>errors.message</td>
<td>Brief description of the error message. Data type: String</td>
</tr>
<tr>
<td>idList</td>
<td>List of CMDB CI sys_ids. Data type: Array</td>
</tr>
<tr>
<td>partialCIListDueToACLFlag</td>
<td>Flag that indicates if the list of returned CIs is incomplete due to ACL restrictions.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This is not considered an error condition, and no corresponding error information is returned.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: <code>idList</code> is incomplete.</td>
</tr>
<tr>
<td></td>
<td>• false: <code>idList</code> is complete.</td>
</tr>
<tr>
<td>result</td>
<td>Flag that indicates whether the method completed successfully.</td>
</tr>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Success</td>
</tr>
<tr>
<td></td>
<td>• false: Error</td>
</tr>
</tbody>
</table>

// Script example:
```
var getAllCIFunc = function(groupSysId) {
    var parser = new JSONParser();
    var response = sn_cmdbgroup.CMDBGroupAPI.getAllCI(groupSysId, false);
    var parsed = parser.parse(response);
    if (parsed.result) {
        gs.info("succeed to retrieve ci list: " + parsed.idList);
    } else {
        gs.info("fail to retrieve list, errors: " + JSON.stringify(parsed.errors));
    }
}
var groupExists = "d0d2d25113152200eef2dd828144b0e4";
var groupContainsInvalidSavedQuery = "e685a2c3d7012200de92a5f75e610387";
getAllCIFunc(groupExists);
getAllCIFunc(groupContainsInvalidSavedQuery);
```

Output:
```
// Successful response
{
    'result':true,
    'partialCIListDueToACLFlag': false,
    'idList':[
        '3a5dd3db0a8ce0100655f1ec66ed42c',
        '6b43105c373010000deabfc8bcbe5db2'
    ]
}

// Error response
{
"errors": null,
"partialCIListDueToACLFlag": false,
"idList":null
}
```
CMDBGroupAPI - getAllCIFromQueryBuilder(String groupId, Boolean requireCompleteSet, Boolean requireAllQueryNodesCis)

Returns all configuration items (CIs) returned from all saved query builders' query IDs for the specified group.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupId</td>
<td>String</td>
<td>Sys_id of the Configuration Management Database (CMDB) group.</td>
</tr>
<tr>
<td>requireCompleteSet</td>
<td>Boolean</td>
<td>Optional, but must be passed if requireAllQueryNodesCis is passed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Flag that indicates whether an empty string is returned if any CIs are filtered out by access control list (ACL) restrictions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Return empty string.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Don’t return value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td>requireAllQueryNodesCis</td>
<td>Boolean</td>
<td>Optional. Flag that indicates whether to return CIs from all CMDB classes of the query.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Return CIs from all columns.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Only return CIs from the starting node of the query builder query.</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Default: false</td>

getAllCIFromQueryBuilderFunc(groupExists);
getAllCIFromQueryBuilderFunc(groupContainsInvalidSavedQuery);
```

Output:
CMDBGroupAPI - getManualCIList(String groupId, Boolean requireCompleteSet)

Returns the CMDB group’s manual CI list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupId</td>
<td>String</td>
<td>The sysId of the CMDB group.</td>
</tr>
<tr>
<td>requireCompleteSet</td>
<td>Boolean</td>
<td>When true, returns an error string if any CIs are filtered out by ACL restrictions.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A JSON formatted string in the format</td>
</tr>
</tbody>
</table>

```json
{
  'result':false,
  'errors':[
    {'message':'Group does not exist','error':'GROUP_SYS_ID_IS_NOT_FOUND'}
  ],
  'partialCIListDueToACLFlag':false,
  'idList':[]
}
```
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>}, 'partialCIListDueToACLFlag':false,</td>
</tr>
<tr>
<td></td>
<td>'idList':['sys_id_1', 'sys_id2'] }</td>
</tr>
</tbody>
</table>

Where

- **result** - a boolean flag. When true the method was successful.
- **errors** - a list of errors with a message and error code.
- **partialCIListDueToACLFlag** - a Boolean flag. When true, the idList is incomplete due to an ACL restriction. When false, the idList is complete.
- **idList** - an array of cmdb_ci sys_ids

When not successful, returns one of the errors

- GROUP_SYS_ID_IS_NOT_FOUND
- GROUP_SYS_ID_IS_EMPTY
- FAIL_TO_INSERT_GROUP_CI_PAIR
- FAIL_TO_INSERT_GROUP_QUERY_ID_PAIR
- CI_CAN_NOT_FOUND

**CMDBGroupAPI - getSavedQueryIdList(String groupId, Boolean requireCompleteSet)**

Returns the query builder's query IDs for the specified CMDB group.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupId</td>
<td>String</td>
<td>The sysId of the CMDB group.</td>
</tr>
<tr>
<td>requireCompleteSet</td>
<td>Boolean</td>
<td>When true, returns an empty string if any CIs are filtered out by ACL restrictions.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A JSON formatted string in the format</td>
</tr>
</tbody>
</table>

```json
{ 'result':false,
  'errors':[ {'message':'Group does not exist',
              'error':'GROUP_SYS_ID_IS_NOT_FOUND'},
            ],  // another error if it exists
  'partialCIListDueToACLFlag':false,
  'idList':['sys_id_1', 'sys_id2'] }
```

Where

- result - a boolean flag. When true the method was successful.
- errors - a list of errors with a message and error code.
- partialCIListDueToACLFlag - a Boolean flag. When true, the idList is incomplete due to an ACL restriction. When false, the idList is complete.
- idList - an array of cmdb_ci sys_ids

When not successful, returns one of the errors

GROUP_SYS_ID_IS_NOT_FOUND, GROUP_SYS_ID_IS_EMPTY,
FAIL_TO_INSERT_GROUP_CI_PAIR,
FAIL_TO_INSERT_GROUP_QUERY_ID_PAIR,
CI_CAN_NOT_FOUND, SAVED_QUERY_ID_NOT_FOUND,

succeed to retrieve saved query id list: 5d498532d7c12200de92a5f75e6103ce
fail to retrieve list, errors:

  [{"message":"Group does not exist","error":"GROUP_SYS_ID_IS_NOT_FOUND"}]

CMDBGroupAPI - setManualCIList(String groupid, String ciSysIds)
Sets the manual CI list for the specified group. The existing manual CI list is overwritten. CI sysIds not found in the cmdb_ci table are ignored.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupId</td>
<td>String</td>
<td>The sysId of the CMDB group.</td>
</tr>
<tr>
<td>ciSysIds</td>
<td>String</td>
<td>Comma separated list of CI sysIds.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A JSON formatted string in the format</td>
</tr>
</tbody>
</table>

```json
{
  'result':false,
  'errors':[ {'message':'Group does not exist',
               'error':'GROUP_SYS_ID_IS_NOT_FOUND'},
              {} // another error if it exists
  ],
  'partialCIListDueToACLFlag':false,
  'idList':['sys_id_1', 'sys_id2']
}
```

Where

- result - a boolean flag. When true the method was successful.
- errors - a list of errors with a message and error code.
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• partialCIListDueToACLFlag - a Boolean flag. When true, the idList is incomplete due to an ACL restriction. When false, the idList is complete.</td>
<td></td>
</tr>
<tr>
<td>• idList - an array of cmdb_ci sys_ids</td>
<td></td>
</tr>
</tbody>
</table>

When not successful, returns one of the errors:
GROUP_SYS_ID_IS_NOT_FOUND, GROUP_SYS_ID_IS_EMPTY, FAIL_TO_INSERT_GROUP_CI_PAIR, FAIL_TO_INSERT_GROUP_QUERY_ID_PAIR, CI_CAN_NOT_FOUND, SAVED_QUERY_ID_NOT_FOUND, ERROR_DURING_QUERY_BUILDER_PROCESS_QUERY, TIMEOUT_DURING_QUERY_BUILDER_PROCESS_QUERY, NOT_COMPLETE_DURING_QUERY_BUILDER_PROCESS_QUERY, MAX_LIMIT_DURING_QUERY_BUILDER_PROCESS_QUERY, GROUP_API_TIMEOUT, EXCEPTION_FROM_EXECUTE_QUERY, SOME_CI_NOT_VISIBLE_DUE_TO_SECURITY_CONSTRAINT

// Script example:
var setManualCIListFunc = function(groupSysId, manualCIList) {
    var parser = new JSONParser();
    var response = sn_cmdbgroup.CMDBGroupAPI.setManualCIList(groupSysId, manualCIList);
    var parsed = parser.parse(response);
    if (parsed.result) {
        gs.info("succeed to set manual ci list");
    } else {
        gs.info("fail to set manual ci list, errors: " + JSON.stringify(parsed.errors));
    }

setManualCIListFunc(group, manualCIList);
setManualCIListFunc(groupDoesNotExist, manualCIList);

Output: (Line breaks added for formatting.)
succeed to set manual ci list
fail to set manual ci list, errors: [{"message":"Group does not exist","error": "GROUP_SYS_ID_IS_NOT_FOUND"}]
CMDBGroupAPI - setSavedQueryIdList(String groupld, String queryIds)

Sets the saved query ID list for the specified group. The existing query ID list is overwritten. Query sysIds not found in the qb_saved_query table are ignored.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupld</td>
<td>String</td>
<td>The sysId of the CMDB group.</td>
</tr>
<tr>
<td>queryIds</td>
<td>String</td>
<td>Comma separated list of saved query sysIds.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A JSON formatted string in the format</td>
</tr>
</tbody>
</table>

```
{ 'result':false,
  'errors':[ {'message':'Group does not exist',
    'error':'GROUP_SYS_ID_IS_NOT_FOUND'},
  { } // another error if it exists
},
'partialCIListDueToACLFlag':false,
'idList':['sys_id_1', 'sys_id2'] }
```

Where

- result - a boolean flag. When true the method was successful.
- errors - a list of errors with a message and error code.
- partialCIListDueToACLFlag - a Boolean flag. When true, the idList is incomplete due to an ACL restriction. When false, the idList is complete.
- idList - an array of cmdb_ci sys_ids

When not successful, returns one of the errors

GROUP_SYS_ID_IS_NOT_FOUND, GROUP_SYS_ID_IS_EMPTY,
FAIL_TO_INSERT_GROUP_CI_PAIR,
FAIL_TO_INSERT_GROUP_QUERY_ID_PAIR,

```

**CMDBQueryBuilderAPI - Global**

Use the `CMDBQueryBuilderAPI` to retrieve Query Builder saved query execution details in server-side scripts.

To access this API you must activate the Configuration Management (CMDB) (com.snc.cmdb) plugin.

For more information on the CMDB Query Builder, see [Querying the CMDB](Querying the CMDB).
CMDBQueryBuilderAPI - getSavedQueryExecutionDetails(String savedQueryName, Boolean executeQuery, Number timeout)

Returns the execution details for a specified Configuration Management Database (CMDB) Query Builder saved query.

Optionally you can specify whether to execute the query or not, in order to return its most recent query execution details. You can also override the default timeout limit for the execution of the query.

In the event of a timeout or memory issue while executing the query, you can fine tune the query batch size to help alleviate these problems. For additional information, see Batch size for Query Builder saved queries.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>executeQuery</td>
<td>Boolean</td>
<td>Optional. Flag that indicates whether to execute the specified query or not.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Execute the specified query and return its execution details.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not execute the specified query. Return the most recent execution</td>
</tr>
<tr>
<td></td>
<td></td>
<td>details of the query.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: False</td>
</tr>
<tr>
<td>savedQueryName</td>
<td>String</td>
<td>Name of the CMDB Query Builder saved query for which to return query</td>
</tr>
<tr>
<td></td>
<td></td>
<td>execution details.</td>
</tr>
<tr>
<td>timeout</td>
<td>Number</td>
<td>Optional. Integer value that overrides the default query execution timeout</td>
</tr>
<tr>
<td></td>
<td></td>
<td>limit of five minutes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Unit: Seconds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: Five minutes</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Error</td>
<td>Error code and message. Returned when the query execution fails or the</td>
</tr>
<tr>
<td></td>
<td>specified query is not found.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query_id</td>
<td>Saved query Execution ID (sys_id). Obtained from the Query Status [qb_query_status] table.</td>
</tr>
<tr>
<td>table_name</td>
<td>Name of the table that contains the execution query details.</td>
</tr>
<tr>
<td>status</td>
<td>Status of the query execution.</td>
</tr>
<tr>
<td>COMPLETE</td>
<td>Execution is complete.</td>
</tr>
<tr>
<td>FAILED</td>
<td>Error occurred while executing query.</td>
</tr>
<tr>
<td>TIME_OUT</td>
<td>Query execution timed out.</td>
</tr>
<tr>
<td>MAX_LIMIT</td>
<td>Maximum number of return results reached.</td>
</tr>
</tbody>
</table>

Error examples:
- "error": "QUERY_EXECUTION_NOT_FOUND", "message": "Query execution details not found. Please execute the query."
- "error": "QUERY_NOT_FOUND", "message": "Given saved query not found. Please make sure you are passing the name of a saved query."
- "error": "QUERY_EXECUTION_FAILED", "message": "Query execution failed. Please use a valid query."

This example shows how to call the `getSavedQueryExecutionDetails()` method.

```java
SNC.CMDBQueryBuilderAPI.getSavedQueryExecutionDetails('Test', true);
```

Output:
```
{"query_id":"024fd53a7773330033b5270bba106141",
"table_name":"u_cmdb_qb_result_598918aacb4dbf3f1a8dce6a5d57151a4e2",
"status":COMPLETE}
```

This example shows how to call the `getSavedQueryExecutionDetails()` method and override the default query execution timeout value to 10 minutes.

```java
SNC.CMDBQueryBuilderAPI.getSavedQueryExecutionDetails('Test', true, 600);
```

Output:
```
{"query_id":"024fd53a7773330033b5270bba106141",
"table_name":"u_cmdb_qb_result_598918aacb4dbf3f1a8dce6a5d57151a4e2",
"status":COMPLETE}
```
CMDBTransformUtil - Global

The CMDBTransformUtil class uses the Identification and Reconciliation (IRE) framework to minimize creation of duplicate configuration items (CI).

The IRE framework also reconciles CI attributes by only accepting information from authorized sources when updating the CMDB in onBefore transform map scripts. This class cannot be used in other scripts. For additional information on how the Identification and Reconciliation framework operates, see CMDB Identification and Reconciliation.

CMDBTransformUtil - CMDBTransformUtil()

Creates a CMDBTransformUtil object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var cmdbUtil = new CMDBTransformUtil();
```

CMDBTransformUtil - getError()

Returns any errors generated by the previous identifyAndReconcile() or identifyAndReconcileEnhanced() method call.

Use this method in onBefore transform map scripts to obtain errors. Use the hasError() method to first detect any errors from the identifyAndReconcile() or identifyAndReconcileEnhanced() method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Error message from identifyAndReconcile() or identifyAndReconcileEnhanced().</td>
</tr>
</tbody>
</table>
// Add this code to the onBefore transform map script
// Call CMDB API to do Identification and Reconciliation of the current row
var cmdbUtil = new CMDBTransformUtil();
cmdbUtil.setDataSource('ImportSet');
cmdbUtil.identifyAndReconcileEnhanced(source, map, log);
ignore = true;

if (cmdbUtil.hasError()) {
    var errorMessage = cmdbUtil.getError();
    log.error(errorMessage);
} else {
    log.info('IE Output Payload: ' + cmdbUtil.getOutputPayload());
    log.info('Imported CI: ' + cmdbUtil.getOutputRecordSysId());
}

Scoped equivalent
There is no scoped equivalent for this method.

CMDBTransformUtil - getOutputPayload()

Returns the JSON payload from the previous identifyAndReconcile() or identifyAndReconcileEnhanced() method call.

Use this method in onBefore transform map scripts.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;String&gt;</td>
<td>JSON formatted string that is a list of results for the configuration items in the input string. Each result string is in the format 'items: [[]], relations: [[]]', where each item within items and relations lists contains name-value pairs.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>&lt;String&gt;.additionalCommittedItems</code></td>
<td>No values are currently returned.</td>
</tr>
<tr>
<td><code>&lt;String&gt;.additionalCommittedRelations</code></td>
<td>No values are currently returned.</td>
</tr>
<tr>
<td><code>&lt;String&gt;.items</code></td>
<td>List of objects that describe created or updated CIs. Data type: Array</td>
</tr>
</tbody>
</table>

```json
"items": {
  "additionalRelatedItems": [Array],

  }  
] | |
| <String>.items.additionalRelatedItems.className | Class/table name (sys_class_name) of the CI that was created or updated.  
Data type: String |
| <String>.items.additionalRelatedItems.inputIndices | Index of the corresponding input item. For top-level items it is a list of integers. For related or lookup items, it is list of JSON objects.  
Data type: Array of Numbers or Array of objects |
| "inputIndices": [  
  {  
    "mainIndex": Number,  
    "subIndex": Number  
  }  
] | |
| <String>.items.additionalRelatedItems.inputIndices.mainIndex | Index value from the request body items array that corresponds to the CI parent the additional related item.  
Data type: Number |
| <String>.items.additionalRelatedItems.inputIndices.subIndex | Index value from the request body items.lookup array that corresponds to the additional related item.  
Data type: Number |
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| `<String>.items.additionalRelatedItems.operation` | Type of operation. Possible values:  
- INSERT: New CI was inserted into the database.  
- NO_CHANGE: No CI changes were made.  
- UPDATE: Existing CI was updated.  
  Data type: String |
| `<String>.items.additionalRelatedItems.sysId` | Sys_id of the additional related items.  
  Data type: String |
| `<String>.items.className` | Class/table name (sys_class_name) of the CI that was created or updated.  
  Data type: String |
| `<String>.items.duplicateIndices` | List of indexes of CIs that are duplicates of the current item.  
  Data type: Array |
| `<String>.items.errorCount` | Number of errors.  
  Data type: Number |
| `<String>.items.errors` | Array of objects in which each object describes an error encountered while processing this CI.  
  Data type: Array |

```
"errors": [  
  {  
    "error": "String",  
    "message": "String"
  }
]```
<table>

</tr>
</tbody>
</table>

Data type: String

`<String>.items.identificationAttempts.attributes` List of CI identifier entry attributes that were used during the identification process. Data type: Array

Attribute names and types depend on the request body data and the identifier in use, such as:

```
"attributes": {
  "serial_number": "String",
  "serial_number_type": "String"
}
```

`<String>.items.identificationAttempts.hybridEntryCiAttributes` No values are currently returned.

`<String>.items.identificationAttempts.identifierName` Identifier rule used for this CI identification attempt. Data type: String

`<String>.items.identificationAttempts.searchOnTable` Name of the table searched during the identification process.
<table>

}
Scoped equivalent

There is no scoped equivalent for this method.

**CMDBTransformUtil - getOutputRecordSysId()**

Returns the sys_id of the configuration item (CI) that was inserted or updated.

Use this method in onBefore transform map scripts.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

</tbody>
</table>

### Returns

JSON format for the results for the payload.

Data type:

```json
{
  "additionalCommittedItems": [Array],
  "additionalCommittedRelations": [Array],
  "hasError": "Boolean",
  "hasWarning": "Boolean",
  "items": [Array],
  "relations": [Array],
  "summary": {Object}
}
```

**<String>.additionalCommittedItems**

List of CIs that were committed during the IRE processing of the current payload.
Returns (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>not present in the current input payload.</td>
<td></td>
</tr>
</tbody>
</table>

Data type:

```json
"additionalCommittedItems": [
  {
    "className": "String",
    "errorCount": Number,
    "operation": "String",
    "identificationAttempts": [Array],
    "inputIndices": [Array],
    "markers": [Array],
    "mergedPayloads": [Array],
    "sysId": "String"
  }
]```

### <String>.additionalCommittedItems.className

Sys_class name of this additional CI.

**Data type:** String

### <String>.additionalCommittedItems.errorCount

Number of errors encountered while processing this additional CI.

**Data type:** Number

### <String>.additionalCommittedItems.errors

Array of objects that describes errors encountered while processing this additional CI.

**Data type:** Array

```json
"errors": [
  {
    "error": "String",
    "message": "String"
  }
]```

### <String>.additionalCommittedItems.errors.error

Type of error encountered while processing the additional CI.

**Data type:** String
Returns (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;String&gt;.summary.&lt;class_name&gt;.additionalInsertedItemCount</code></td>
<td>Number of items inserted due to processing of partial payloads. Data type: Number</td>
</tr>
<tr>
<td><code>&lt;String&gt;.summary.&lt;class_name&gt;.errorCount</code></td>
<td>Number of errors encountered when processing items. Data type: Number</td>
</tr>
<tr>
<td><code>&lt;String&gt;.summary.&lt;class_name&gt;.incompleteItemCount</code></td>
<td>Number of items inserted in the CMDB IRE Incomplete Payloads table. Data type: Number</td>
</tr>
<tr>
<td><code>&lt;String&gt;.summary.&lt;class_name&gt;.insertedItemCount</code></td>
<td>Number of items created. Data type: Number</td>
</tr>
<tr>
<td><code>&lt;String&gt;.summary.&lt;class_name&gt;.partialItemCount</code></td>
<td>Number of items saved in the Partial Payload table [cmdb_ire_partial_payloads]. Data type: Number</td>
</tr>
<tr>
<td><code>&lt;String&gt;.summary.&lt;class_name&gt;.skippedItemCount</code></td>
<td>Number of items that were skipped. Data type: Number</td>
</tr>
<tr>
<td><code>&lt;String&gt;.summary.&lt;class_name&gt;.unchangedItemCount</code></td>
<td>Number of items that had entries but were not modified. Data type: Number</td>
</tr>
<tr>
<td><code>&lt;String&gt;.summary.&lt;class_name&gt;.updatedItemCount</code></td>
<td>Number of items updated. Data type: Number</td>
</tr>
<tr>
<td><code>&lt;String&gt;.summary.&lt;class_name&gt;.warningCount</code></td>
<td>Number of items that generated a warning when processed. Data type: Number</td>
</tr>
</tbody>
</table>
This code example shows how to obtain the payload of an ImportSet, where you can then update the payload, and then set the new payload before calling the cmdbUtil.identifyAndReconcileEnhanced() method to process the payload.

```javascript
// Add this code to the onBefore transform map script
// Ability to modify the payload using get and set APIs
// Call cmdbUtil API to do Identification and Reconciliation of current row
var cmdbUtil = new CMDBTransformUtil();
cmdbUtil.setDataSource('ImportSet');
var payload = cmdbUtil.getPayload(source, map, log);
// Modify the payload here
cmdbUtil.setPayload(payload);
cmdbUtil.identifyAndReconcileEnhanced(source, map, log);
ignore = true;

if (cmdbUtil.hasError()) {
    var errorMessage = cmdbUtil.getError();
    log.error(errorMessage);
} else {
    log.info('IE Output Payload: ' + cmdbUtil.getOutputPayload());
    log.info('Imported CI: ' + cmdbUtil.getOutputRecordSysId());
}
```

**CMDBTransformUtil - hasError()**

Determines if an error occurred in the previous identifyAndReconcile() or identifyAndReconcileEnhanced() method call.

Use this method in onBefore transform map scripts.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Boolean</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• true</td>
<td>An error occurred</td>
</tr>
<tr>
<td>• false</td>
<td>No error occurred</td>
</tr>
</tbody>
</table>

// Add this code to the onBefore transform map script
// Call CMDB API to do Identification and Reconciliation of current row
var cmdbUtil = new CMDBTransformUtil();
cmdbUtil.setDataSource('ImportSet');
cmdbUtil.identifyAndReconcileEnhanced(source, map, log);
ignore = true;

if (cmdbUtil.hasError()) {
    var errorMessage = cmdbUtil.getError();
    log.error(errorMessage);
} else {
    log.info('IE Output Payload: ' + cmdbUtil.getOutputPayload());
    log.info('Imported CI: ' + cmdbUtil.getOutputRecordSysId());
}

Scoped equivalent
There is no scoped equivalent for this method.

CMDBTransformUtil - identifyAndReconcile(Object source, Object map, Object log)

Inserts or updates a configuration item (CI) in the Configuration Management Database (CMDB).

Use this method in onBefore transform map scripts. Using this method instead of relying on the transform to insert or update the configuration item record reduces duplicate entries in the CMDB. For additional information, see Apply CI Identification and Reconciliation to Import Sets.

To prevent the transform from adding or updating the record a second time, set ignore = true.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>Object</td>
<td>Global object available in transform map scripts that holds the incoming record.</td>
</tr>
<tr>
<td>map</td>
<td>Object</td>
<td>Map object available in transform map scripts that holds the current transform map record.</td>
</tr>
<tr>
<td>log</td>
<td>Object</td>
<td>Log object available in transform map scripts.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This code example shows how to call the `identifyAndReconcile()` method to process the current row of the input payload.

```java
// Add this code to the onBefore transform map script
// Call CMDBTransformUtil API to do Identification and Reconciliation of the current row
var cmdbUtil = new CMDBTransformUtil();
cmdbUtil.identifyAndReconcile(source, map, log);
ignore = true;
```

### CMDBTransformUtil - identifyAndReconcileEnhanced(Object source, Object map, Object log)

Inserts or updates a configuration item (CI) in the Configuration Management Database (CMDB).

In addition to providing the functionality of the `CMDBTransformUtil.identifyAndReconcile()` method, this method also supports:

- Handling partial payloads
- Handling partial commits
- Removing duplicate items within a payload
- Generating output summaries

For additional information on Identification and Reconciliation and more detailed explanations of the data used by this method, see [Identification and Reconciliation (IRE)](https:// servicenow.com).
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>Object</td>
<td>Global object available in transform map scripts that holds the incoming record.</td>
</tr>
<tr>
<td>map</td>
<td>Object</td>
<td>Map object available in transform map scripts that holds the current transform map record.</td>
</tr>
<tr>
<td>log</td>
<td>Object</td>
<td>Log object available in transform map scripts.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

This code example shows how to call the `identifyAndReconcileEnhanced()` method to process the passed in payload.

```java
// Add this code to the onBefore transform map script
// Call CMDBTransformUtil API to do Identification and Reconciliation
var cmdbUtil = new CMDBTransformUtil();
cmdbUtil.identifyAndReconcileEnhanced(source, map, log);
ignore = true;
```

**CMDBTransformUtil - logTransformStats(Object log)**

Logs the number of configuration items (CI) inserted, updated, skipped, or that had errors.

Use this method in onComplete transform map scripts.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log</td>
<td>Object</td>
<td>Log object available in transform map scripts.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var cmdbUtil = new CMDBTransformUtil();
cmdbUtil.logTransformStats(log);

Scoped equivalent
There is no scoped equivalent for this method.

CMDBTransformUtil - setDataSource(String source)
Sets the data source to use when the identifyAndReconcile() or identifyAndReconcileEnhanced() method is called.

Use this method in onBefore transform map scripts. If this method is not called, the default value ImportSet.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>String</td>
<td>Data source for the source configuration item record.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

// Add this code to the onBefore transform map script
// Call CMDB API to do Identification and Reconciliation of current row
var cmdbUtil = new CMDBTransformUtil();
cmdbUtil.setDataSource('ImportSet');
cmdbUtil.identifyAndReconcileEnhanced(source, map, log);
ignore = true;

if (cmdbUtil.hasError()) {
    var errorMessage = cmdbUtil.getError();
    log.error(errorMessage);
} else {
    log.info('IE Output Payload: ' + cmdbUtil.getOutputPayload());
    log.info('Imported CI: ' + cmdbUtil.getOutputRecordSysId());
}

Scoped equivalent
There is no scoped equivalent for this method.
CMDBUtil - Global

The CMDBUtil API provides utility methods for creating and managing table relationships in the configuration management database (CMDB) and managing CMDB baselines.

CMDBUtil is a JavaScript-accessible ScriptableObject. The CMDBUtil API has dynamic and static methods. You access dynamic methods by creating a SNC.CMDBUtil object. You access static methods by using SNC.CMDBUtil global object to call the methods.

This example creates a CMDBUtil object.

```javascript
var cu = new SNC.CMDBUtil();
cu.baselineProposedChangesGenDIFF(current, action.get('sysparm_changeset'));
```

This example calls a static method.

```javascript
var output = SNC.CMDBUtil.getAllChildrenOfAsCommaList('cmdb_ci_computer');
```

Use these methods to manage CMDB table relationships and baselines.

CMDBUtil - baselineProposedChangesApplyChanges(GlideRecord proposedChanges)

Applies proposed changes in a task_ci record that represent an update set for all CIs associated with the task.

This is a dynamic method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proposedChanges</td>
<td>GlideRecord</td>
<td>The collection of proposed changes in the change request (CHG).</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
//Where current is a GlideRecord and action is the current UI action
var base = new SNC.CMDBUtil();
base.baselineProposedChangesApplyChanges(current);
```
CMDBUtil - baselineProposedChangesGenDiff(GlideRecord current, String changeSet)
Generates the XML for proposed changes diff, and adds it to the corresponding task_ci record.
This is a dynamic method.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>current</td>
<td>GlideRecord</td>
<td>The GlideRecord that contains the collection of proposed changes.</td>
</tr>
<tr>
<td>changeSet</td>
<td>String</td>
<td>The sysid of the task_ci record that represents the change set to use.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

//Where current is a GlideRecord and action is the current UI action
var base = new SNC.CMDBUtil();
base.baselineProposedChangesGenDiff(current, action.get('sysparm_changeset'));

CMDBUtil - bootstrap(String dictFile)
Bootstrap the environment by creating the database, creating the system dictionary table, and having the system dictionary table describe itself.
This is a static method.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dictFile</td>
<td>String</td>
<td>The file name including path, of the dictionary to load.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
CMDBUtil - createCIRelationship(String tableName, String parentField, String childField, String parentDesc, String childDesc)

Creates the specified CI relationship using the specified invocation parameters.

If called without the first parameter, passing only four parameters, defaults to the CI Relationship [cmdb_rel_ci] table.

This is a dynamic method.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The table name.</td>
</tr>
<tr>
<td>parentField</td>
<td>String</td>
<td>The parent field.</td>
</tr>
<tr>
<td>childField</td>
<td>String</td>
<td>The child field</td>
</tr>
<tr>
<td>parentDesc</td>
<td>String</td>
<td>The parent relationship descriptor.</td>
</tr>
<tr>
<td>childDesc</td>
<td>String</td>
<td>The child relationship descriptor.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CMDBUtil - getAllChildrenOfAsCommaList(String baseTable)

Gets all the child tables of the specified table as a comma-separated list.

This is a static method.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseTable</td>
<td>String</td>
<td>The base table name.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A comma-separated list of sys_ids of tables extending the base table.</td>
</tr>
</tbody>
</table>
//Where cmdv_ci_computer is a table.
var output = SNC.CMDBUtil.GetAllChildrenOfAsCommaList('cmdb_ci_computer');
gs.print(output);

CMDBUtil - getCMDBViews()

Gets all the records in the CMDB View [cmdb_view] table.

This is a dynamic method.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ArrayList</td>
<td>The records in the CMDB view table.</td>
</tr>
</tbody>
</table>

CMDBUtil - getTables0(String tableName)

Gets a list of all the parents of a table.

This is a static method.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>tableName</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ArrayList</td>
<td>List of tables that are parents of the specified table.</td>
</tr>
</tbody>
</table>
**CMDBUtil - isExcludedFromBR(String className)**

Determines whether a CI class is defined in the Business Rule Exclusion Lists [cmdb_business_rule_exclusions] table. Use this method in an advanced condition to prevent a business rule from executing on excluded CI classes.

For example, the Create Asset on insert business rule uses this method in the advanced condition to prevent the rule from creating assets for CI classes such as cmdb_ci_qualifier, cmdb_ci_endpoint, cmdb_ci_storage_volume, and cmdb_ci_vcenter_datastore_disk. Define classes for exclusion in the Business Rule Exclusion Lists [cmdb_business_rule_exclusions] table.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>className</td>
<td>String</td>
<td>Name of the class to check for exclusion.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the class is defined in the Business Rule Exclusion Lists [cmdb_business_rule_exclusions] table; otherwise, false.</td>
</tr>
</tbody>
</table>

//Returns true if the cmdb_ci_endpoint class is defined in the Business Rule Exclusion Lists table
var exclusion = SNC.CMDBUtil.isExcludedFromBR("cmdb_ci_endpoint");

//Advanced condition that prevents business rules from executing on classes in the Business Rule Exclusion Lists table
(!SNC.CMDBUtil.isExcludedFromBR(current.getTableName()))

**CMDBUtil - processCIChange(GlideRecord event, GlideRecord target)**

Wraps the call to RelationshipEventProcessor(), which processes any changes to CI relationships.

This is a dynamic method.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>event</td>
<td>GlideRecord</td>
<td>The event record.</td>
</tr>
</tbody>
</table>
CMDBUtil - processRelChange(GlideRecord event, GlideRecord current, String relType, String triplet)

Wraps the call to `RelationshipEventProcessor()`, which processes any changes to CI relationships, with the specified type and triplet.

This is a dynamic method.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>event</td>
<td>GlideRecord</td>
<td>The event record</td>
</tr>
<tr>
<td>current</td>
<td>GlideRecord</td>
<td>The current record, which is either the relation record or a user record if the current process is a deletion.</td>
</tr>
<tr>
<td>relType</td>
<td>String</td>
<td>The type of relation that changed.</td>
</tr>
<tr>
<td>triplet</td>
<td>String</td>
<td>The child, parent, and class name from the relation that changed.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CMDBUtil - removeCIRelationship(String tableName, String parentField, String childField, String parentDesc, Object childDesc)

Deletes the specified CI relationship.
If called without the first parameter, passing only four parameters, defaults to the CI Relationship [cmdb_rel_ci] table.

This is a dynamic method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The table name</td>
</tr>
<tr>
<td>parentField</td>
<td>String</td>
<td>The parent field</td>
</tr>
<tr>
<td>childField</td>
<td>String</td>
<td>The child field</td>
</tr>
<tr>
<td>parentDesc</td>
<td>String</td>
<td>The parent relationship descriptor</td>
</tr>
<tr>
<td>childDesc</td>
<td>Object</td>
<td>The child relationship descriptor</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**CMDBUtil - reParentTable(String table, String oldParent, String newParent)**

Changes the parent of the given table to the new parent.

This is a static method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>The table to re-parent</td>
</tr>
<tr>
<td>oldParent</td>
<td>String</td>
<td>The old parent</td>
</tr>
<tr>
<td>newParent</td>
<td>String</td>
<td>The new parent</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True, if successful; otherwise, false.</td>
</tr>
</tbody>
</table>
Color - Scoped, Global

Creates a Color object used to define color attributes that you can apply to elements in a PDF; such as cells, tables, and lines.

This API is part of the ServiceNow PDF Generation Utilities plugin (com.snc.apppdfgenerator) and is provided within the sn_pdfgeneratorutils namespace. The plugin is activated by default.

This API is a component used with the Document API to generate a PDF.

Color - Color(Array colors)

Instantiates a new Color object with RGB values.

Color can be applied to the following scenarios:

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>colors</td>
</tr>
</tbody>
</table>

The following example shows how to create a Color object.

```javascript
var color = new sn_pdfgeneratorutils.Color([0.1, 0.9, 0.5]); //given as object containing RGB values
```

Color – equals(Color color)

Indicates whether the values of two different color objects match.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>color</td>
</tr>
<tr>
<td>Returns</td>
</tr>
<tr>
<td>---</td>
</tr>
<tr>
<td><strong>Type</strong></td>
</tr>
</tbody>
</table>
| Boolean | Flag that indicates whether the values of two color objects match.  
Valid values:  
• true: The colors match.  
• false: The colors do not match. |

The following example shows how to create two color objects and determine if the colors match.

```javascript
var color1 = new sn_pdfgeneratorutils.Color([1,0.5,0.5]);  // given as an array of RGB values
var color2 = new sn_pdfgeneratorutils.Color([0.8,0.5,0.5]);         // given as an array of RGB values
var isequal = color1.equals(color2);
```

**Color – getGrayColor(Number grayScale)**

Returns a black, gray, or white color object.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>grayScale</td>
</tr>
</tbody>
</table>

The following example shows how to create a color object that is 50% grayscale.

```javascript
var grayColor = new sn_pdfgeneratorutils.Color.getGrayColor(0.5);
```

**Color – setColorValue(Array colors)**

Creates color with given values and enables you to change the values of an existing color. Each of the values must be from 0 through 1.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>colors</td>
<td>Array</td>
<td>Three numbers indicating RGB values using a decimal value from 0 through 1. For example, in [0.1, 0.9, 0.5], the value of the first position is red, second is green, and third is blue. Also, [0, 0, 0] is solid black, [0.5, 0.5, 0.5] is solid gray, and [1, 1, 1] is solid white.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to change the values of an existing color.

```javascript
var color = new sn_pdfgeneratorutils.Color([1,0.5,0.5]); //given as array of RGB values;
color.setColorValue(color);
```

**Color – setOpacity(Number opacity)**

Sets the level of color opacity.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color</td>
<td>Color</td>
<td>Floating decimal value from 0 through 1, in which 0 is fully transparent and 1 is fully opaque.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to create a color object and set its opacity to 50 percent.

```javascript
var color = new Color([1,0.5,0.5]);
color.setOpacity(0.5);
```
ConnectActionResponse - Global

The ConnectActionResponse API provides a method to create a GlideRecord. ConnectActionResponse methods are accessed through a global object (response) that is available only in Connect action scripts.

ConnectActionResponse - newRecord(String table, Object values, String view)

Create a GlideRecord in the specified table with the specified values.

Opens a form in the UI based upon the table, which replaces the Table and Document fields in the Live Group Profile record for the associated conversation.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>Name of the table where the record is to be added.</td>
</tr>
<tr>
<td>values</td>
<td>Object</td>
<td>An object of name value pairs where the names are field names in the table and the values are the field values.</td>
</tr>
<tr>
<td>view</td>
<td>String</td>
<td>The form view to load. This parameter is optional.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
response.newRecord("incident", {
  short_description: conversation.document.short_description || ",
  caller_id: conversation.document.opened_by
});
```

ConnectionInfo - Scoped, Global

Use the ConnectionInfo API to get connection attribute information through the connection and credential alias.

You can use this API in scoped applications, or within the global scope. In scoped scripts, use the sn_cc namespace identifier.

For more information on connections and credentials, see Credentials and connection information.
This function retrieves connection attribute information identified by the given connection and credential alias.

```java
var provider = new sn_cc.ConnectionInfoProvider();

// get a jdbc connection in the current domain with the alias ID
//     "6219afbf9f03320021dd7501942e70fc"
var connectionInfo = provider.getConnectionInfo("6219afbf9f03320021dd7501942e70fc");
if (connectionInfo != null) {
    // get data map
    var datamap = connectionInfo.getDataMap();
    gs.info(datamap["name"]);
    gs.info(datamap["connection_url"]);

    // get the same values using getAttribute
    gs.info(connectionInfo.getAttribute("name"));
    gs.info(connectionInfo.getAttribute("connection_url"));

    // get credential attributes
    gs.info(connectionInfo.getCredentialAttribute("user_name"));
    gs.info(connectionInfo.getCredentialAttribute("password"));

    // get extended attributes
    var extendedAttributes = connectionInfo.getExtendedAttributes();
    gs.info(extendedAttributes["name1"]);
}

// get a jdbc connection in the ACME domain with the alias ID
//     "cd5923ff9f03320021dd7501942e70bb"
connectionInfo = provider.getConnectionInfoByDomain("cd5923ff9f03320021dd7501942e70bb",
                                                  "c90d4b084a362312013398f0512720c0d");
if (connectionInfo != null) {
    // get data map
    var datamap = connectionInfo.getDataMap();
    gs.info(datamap["name"]);
}
```

**Scoped ConnectionInfo - getAttribute(String name)**

Returns the value of a `ConnectionInfo` attribute with the specified property name.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of a ConnectionInfo object property.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value of a specified ConnectionInfo property.</td>
</tr>
</tbody>
</table>

```java
// get the same values using getAttribute
gs.info(connectionInfo.getAttribute("name"));
gs.info(connectionInfo.getAttribute("connection_url"));
```

---

**Scoped ConnectionInfo - getCredentialAttribute()**

Returns the value of credential attributes for a specified connection.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Key-value pair map of credential attributes.</td>
</tr>
</tbody>
</table>

```java
// get credential attributes
gs.info(connectionInfo.getCredentialAttribute("user_name"));
gs.info(connectionInfo.getCredentialAttribute("password"));
```

---

**Scoped ConnectionInfo - getDataMap()**

Returns the connection attributes as a collection of key-value pairs.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Key-value pair map of connection attributes.</td>
</tr>
</tbody>
</table>

```java
// get the same values using getDataMap
gs.info(connectionInfo.getDataMap());
```
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Key-value pair map of connection attributes.</td>
</tr>
</tbody>
</table>

```javascript
// get data map
var datamap = connectionInfo.getDataMap();
gs.info(datamap["name"]);
gs.info(datamap["connection_url"]);
```

Scoped ConnectionInfo - getExtendedAttributes()

Returns the extended attributes as a collection of key-value pairs.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Key-value pair map of extended attributes.</td>
</tr>
</tbody>
</table>

```javascript
// get extended attributes
var extendedAttributes = connectionInfo.getExtendedAttributes();
gs.info(extendedAttributes["name1"]);
```

ConnectionInfoProvider - Scoped, Global

Use the ConnectionInfoProvider API to select connection information through the connection alias.

You can use this API in scoped applications, or within the global scope. In scoped scripts, use the `sn_cc` namespace identifier.
This function retrieves connection information identified by the given connection alias.

```
var provider = new sn_cc.ConnectionInfoProvider();

// get a jdbc connection in the current domain with the alias ID
// "6219afbf9f03320021dd7501942e70fc"
var connectionInfo = provider.getConnectionInfo("6219afbf9f03320021dd7501942e70fc");
if (connectionInfo != null) {
    // get data map
    var datamap = connectionInfo.getDataMap();
    gs.info(datamap["name"]);
    gs.info(datamap["connection_url"]);

    // get the same values using getAttribute
    gs.info(connectionInfo.getAttribute("name"));
    gs.info(connectionInfo.getAttribute("connection_url"));

    // get credential attributes
    gs.info(connectionInfo.getCredentialAttribute("user_name");
    gs.info(connectionInfo.getCredentialAttribute("password");

    // get extended attributes
    var extendedAttributes = connectionInfo.getExtendedAttributes();
    gs.info(extendedAttributes["name1"]);
}

// get a jdbc connection in the ACME domain with the alias ID
// "cd5923ff9f03320021dd7501942e70bb"
connectionInfo = provider.getConnectionInfoByDomain("cd5923ff9f03320021dd7501942e70bb",
                                                "c90d4b084a362312013398f051272c0d");
if (connectionInfo != null) {
    // get data map
    var datamap = connectionInfo.getDataMap();
    gs.info(datamap["name"]);
}
```

**ConnectionInfoProvider - ConnectionInfoProvider()**

Selects connection information through the connection alias.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**ConnectionInfoProvider - getConnectionInfo(String aliasID)**

Retrieves a ConnectionInfo object identified by the given aliasID in the current domain.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aliasID</td>
<td>String</td>
<td>Sys_id of a connection alias.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectionInfo</td>
<td>Information about the connection.</td>
</tr>
</tbody>
</table>

```javascript
var provider = new sn_cc.ConnectionInfoProvider();

// get a jdbc connection in the current domain with the alias ID
//   "6219afbf9f03320021dd7501942e70fc"
var connectionInfo = provider.getConnectionInfo("6219afbf9f03320021dd7501942e70fc");
```

**ConnectionInfoProvider - getConnectionInfoByDomain(String aliasID, String domainID)**

Retrieves a ConnectionInfo object identified by the given aliasID for a specific domain.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aliasID</td>
<td>String</td>
<td>Sys_id of a connection alias.</td>
</tr>
<tr>
<td>domainID</td>
<td>String</td>
<td>Sys_id of a domain or global.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConnectionInfo</td>
<td>Connection information.</td>
</tr>
</tbody>
</table>

```javascript
var provider = new sn_cc.ConnectionInfoProvider();

// get a jdbc connection in the ACME domain with the alias ID
//    "cd5923ff9f03320021dd7501942e70bb"
connectionInfo = provider.getConnectionInfoByDomain("cd5923ff9f03320021dd7501942e70bb", "c90d4b084a362312013398f051272c0d");
```

Conversation - Scoped

The Conversation API enables you to create or modify Connect conversations. To use this class in a scoped application, use the `sn_connect` namespace identifier. The Connect Scriptable APIs plugin (ID: com.glide.connect.scriptable) should be enabled to access the Conversation API.

Scoped Conversation - get(String sysID)

Get an existing Connect conversation by sys_id.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysID</td>
<td>String</td>
<td>The sys_id of the conversation record.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Conversation object</td>
</tr>
</tbody>
</table>

```javascript
var conversation = sn_connect.Conversation.get("27b9844c1385030034bb58a12244b037");
```

Scoped Conversation - create(String name)

Create a Connect conversation.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Create a conversation with a specific name.</td>
</tr>
</tbody>
</table>
| type | String | Include a specific conversation type. The type is determined by the type choice list. The base system includes the following type options:  
• connect  
• support  
• group  
• peer  
• qanda  
• team |

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Scriptable Conversation</td>
</tr>
</tbody>
</table>

```javascript
var conversation = sn_connect.Conversation.create({  
    name: "Hello world",  
    type: "connect"  
});
```

## Scoped Conversation - addSubscriber(String sysID)

Add a user to a conversation.

## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysID</td>
<td>String</td>
<td>The sys_ID of the user you want to add to a conversation.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
**Scoped Conversation - removeSubscriber(String sysID)**
Remove a user from a conversation.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>SysID</td>
<td>String</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Scoped Conversation - sendMessage(String body, String field)**
Send a message to a conversation.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>Body</td>
<td>String</td>
</tr>
<tr>
<td>Field</td>
<td>String</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
CostPlanBatchOperations - Global

Provides methods that enable the creation of a large number of cost plan records for demands and projects using batch processing. Use this API instead of GlideRecord to more efficiently create multiple cost plan records.

Use the CostPlanBatchOperations.add() method to add any number of cost plans to a batch queue. Once you have added all the required cost plans, use the CostPlanBatchOperations.process() method to actually create/insert the cost plans in your instance. Until you call the CostPlanBatchOperations.process() method, the add requests remain in the batch queue (they are not yet added to your instance). If for some reason you need to remove all of the cost plans in the batch queue, use the CostPlanBatchOperations.clear() method.

To use this API you must activate the com.snc.financial_planning_pmo plugin.

CostPlanBatchOperations - add(Object costPlan)

Adds one or more cost plans to a specified task (project or demand). Use this method when you want to create multiple cost plans.

Once processed, the cost plans are inserted into the specified project or demand. You can then view and modify them within your instance. For additional information, see Create a project cost plan and Create a demand cost plan.

Note: This method only defines the cost plans to add to your instance. The cost plans are not inserted into your instance until the CostPlanBatchOperations.process() is called.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>costPlan</td>
<td>Object</td>
<td>One or more objects or an array of objects that describe each of the cost plans to add to an existing task.</td>
</tr>
<tr>
<td>costPlan.name</td>
<td>String</td>
<td>Name of the cost plan. Maximum length: 130 characters</td>
</tr>
<tr>
<td>costPlan.task</td>
<td>String</td>
<td>Sys_id of the project or demand to associate with this cost plan. You can</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>locate this value in one of the following tables:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Project [pm_project]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Project Task [pm_project_task]</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Demand [dmn_demand]</td>
</tr>
<tr>
<td>costPlan.unit_cost</td>
<td>Number</td>
<td>Cost of a single unit of the specified resource.</td>
</tr>
<tr>
<td>costPlan.resource_type</td>
<td>String</td>
<td>Sys_id of the record that defines the cost type associated with this cost plan. The available values for this parameter are defined in the Cost Type Definition [resource_type_definition] table.</td>
</tr>
<tr>
<td>costPlan.start_fiscal_period</td>
<td>String</td>
<td>Sys_id of the record that defines the starting fiscal period to associate with this cost plan. The available values for this parameter are defined in the Fiscal period [fiscal_period] table.</td>
</tr>
<tr>
<td>costPlan.end_fiscal_period</td>
<td>String</td>
<td>Sys_id of the record that defines the ending fiscal period to associate with this cost plan. The available values for this parameter are defined in the Fiscal period [fiscal_period] table.</td>
</tr>
<tr>
<td>costPlan.&lt;optional&gt;</td>
<td>Varied</td>
<td>Optional. You can pass in additional parameters to add to a cost plan. The available parameters depend on the type of cost plan that you are creating. Refer to the Cost Plan [cost_plan] table for the list of additional parameters that you can pass.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
This example shows how to add a simple batched cost plan.

```javascript
// Define Array of Cost Plan records in JSON format
var costPlanRecords = [];
costPlanRecords.push(
    {
        name: 'Capital Expense',
        task: 'f7a36d1bd5b8001025c85a35dc96193a', // sys_id of the task
        unit_cost: 1000.00, // decimal
        resource_type: 'a546eaf79330120064f572edb67ff60', // sys_id of the cost type definition
        start_fiscal_period: '091b6e60cb111200f2de77a4634c9c2e', // sys_id of the start fiscal period record
        end_fiscal_period: '0d1b6e60cb111200f2de77a4634c9c2f', // sys_id of the end fiscal period record
        quantity: 1 // Optional cost plan record attributes
    });

var costPlanBatchOperations = new CostPlanBatchOperations();
costPlanBatchOperations.add(costPlanRecords);
var costPlanSysIds = costPlanBatchOperations.process();
```

**CostPlanBatchOperations - clear()**

Removes all cost plan objects that were added using the CostPlanBatchOperations.add() method.

ℹ️ **Note:** This method only works for cost plans that have been added. Once a cost plan is processed, this method cannot remove it. Processed cost plans must be removed manually through the UI.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to clear the batch queue after adding cost plans.
//Define Array of Cost Plan records in JSON format
var costPlanRecords= [];
costPlanRecords.push({
    name:'Capital Expense',
    task:'f7a36d1b958001025c85a35dc96193a', // sys_id of the task
    unit_cost:1000.00, //decimal
    resource_type:'a546eaf79330120064f572edb67ff70', // sys_id of the cost type definition
    start_fiscal_period:'091b6e60cb11200f2de77a46d34c9e2', // sys_id of the start fiscal period record
    end_fiscal_period:'0d1b6e60cb11200f2de77a4634c9c2f', // sys_id of the end fiscal period record
    quantity:1 // Optional cost plan record attributes
});

var costPlanBatchOperations = new CostPlanBatchOperations();
costPlanBatchOperations.add(costPlanRecords);
var costPlanSysIds = costPlanBatchOperations.process();
costPlanBatchOperations.clear();

**CostPlanBatchOperations - process()**

Processes all of the cost plans that were added using the CostPlanBatchOperations.add() method and creates corresponding cost plans and relevant rollups.

Once the cost plans are successfully processed, the cost plan queue is cleared.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Array</td>
</tr>
</tbody>
</table>

This example shows how to process a simple batched cost plan.

//Define Array of Cost Plan records in JSON format
var costPlanRecords= [];
costPlanRecords.push({
name: 'Capital Expense',
task: 'f7a36d1dbd58001025c85a35dc96193a', // sys_id of the task
unit_cost: 1000.00, // decimal
resource_type: 'a546eaf79330120064f572ed572e67ffeb70', // sys_id of the cost type definition
start_fiscal_period: '091b6e60cb111200f2de77a4634c9c2e', // sys_id of the start fiscal period record
end_fiscal_period: '0d1b6e60cb111200f2de77a4634c9c2f', // sys_id of the end fiscal period record
quantity: 1 // Optional cost plan record attributes
});

costPlanBatchOperations = new CostPlanBatchOperations();
costPlanBatchOperations.add(costPlanRecords);
costPlanSysIds = costPlanBatchOperations.process();

CriteriaEvaluator - Global

Implements a general-purpose criteria evaluator.

The general use pattern is to construct the class, add as many criteria as needed, then evaluate.

CriteriaEvaluator - addCriterion(String lhComparand, String operator, String rhComparand)

Adds the criteria to be evaluated.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lhComparand</td>
<td>String</td>
<td>The left hand comparand. Must be a named value in the left hand values input into evaluate().</td>
</tr>
<tr>
<td>operator</td>
<td>String</td>
<td>The operator. Must be one of: equals, starts with, contains, does not contain, ends with, or regex matches.</td>
</tr>
<tr>
<td>rhComparand</td>
<td>String</td>
<td>The right hand comparand. Can be evaluated either as one of the right hand values input to evaluate() or as a literal string.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

CriteriaEvaluator - evaluate(Object lhValues, String rhValues, Boolean any)

Evaluates the criteria.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lhValues</td>
<td>Object</td>
<td>A hashmap of name-value pairs to evaluate the left hand comparands of the criteria.</td>
</tr>
<tr>
<td>rhValues</td>
<td>String</td>
<td>Optional right hand values to use instead of the literal value in evaluating the right hand comparands.</td>
</tr>
<tr>
<td>any</td>
<td>Boolean</td>
<td>If true, any criterion matching suffices for a true result. If false, all criteria must match for a true result.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the supplied values satisfy the criteria, false otherwise.</td>
</tr>
</tbody>
</table>

CSVParser - Scoped

This API provides methods for parsing comma-separated value (CSV) formatted records into an object or an array.

The CSVParser API is in the `sn_impex` namespace.

CSVParser - parseLineToArray(String cvsLine, String delimiter, String quoteCharacter)

Parses passed in CSV formatted content into an array.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>csvLine</td>
<td>String</td>
<td>CSV content to parse.</td>
</tr>
<tr>
<td>delimiter</td>
<td>String</td>
<td>Optional. Character used to delineate the fields in the source CSV content. Default: Comma ','</td>
</tr>
<tr>
<td>quoteCharacter</td>
<td>String</td>
<td>Optional. Character used as the quote character in the source CSV content. Default: Double quote &quot;&quot;</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Array containing the parsed values for each element in the passed-in CSV content. For example:</td>
</tr>
</tbody>
</table>

```
{
  Joe,
  Smith,
  470 W Carmen, Chicago IL, 60640
}
```

This example shows simple CSV formatted content parsed into a returned array.

```js
var csvLine = '"Joe","Smith","1470 W Carmen, Chicago IL, 60640"';
var delimiter = ',';
var quoteCharacter = '"';

var x = new sn_impex.CSVParser().parseLineToArray(csvLine, delimiter, quoteCharacter);

gs.log(x[0]);
gs.log(x[1]);
gs.log(x[2]);
```

Output:

```
Joe
Smith
1470 W Carmen, Chicago IL, 60640
```
CSVParser - parseLineToObject(String cvsLine, Array headers, String delimiter, String quoteCharacter)

Parses passed in CSV formatted content into an object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>csvLine</td>
<td>String</td>
<td>CSV content to parse.</td>
</tr>
<tr>
<td>headers</td>
<td>Array of Strings</td>
<td>Headers associated with the CSV content. These headers must be specified in the same order as the corresponding content in <code>cvsLine</code>. For example, \var headers = ['first_name', 'last_name', 'address'];\</td>
</tr>
<tr>
<td>delimiter</td>
<td>String</td>
<td>Optional. Character used to delineate the fields in the source CSV content. Default: Comma ','</td>
</tr>
<tr>
<td>quoteCharacter</td>
<td>String</td>
<td>Optional. Character used as the quote character in the source CSV content. Default: Double quote &quot;&quot;</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Object containing the header and corresponding value for each element in the passed-in CSV content. For example:</td>
</tr>
</tbody>
</table>

```
{
  first_name: Joe,
  last_name: Smith,
  address: 1470 W Carmen, Chicago IL, 60640
}
```

This example shows CSV formatted content parsed into a returned object.

```
var csvLine = '\"Joe\",\"Smith\",\"1470 W Carmen, Chicago IL, 60640\"';
var headers = ['first_name', 'last_name', 'address'];
var delimiter = ',';
var quoteCharacter = '"';
```
var x = new sn_impex.CSVParser().parseLineToObject(csvLine, headers, delimiter, quoteCharacter);

gs.log(x.first_name);
gs.log(x.last_name);
gs.log(x.address);

Output:

Joe
Smith
1470 W Carmen, Chicago IL, 60640

This example shows an exception response because of an invalid pass of the header parameter.

var csvLine = '"Joe","Smith","1470 W Carmen, Chicago IL, 60640"';
var headers = null;
var delimiter = ',';
var quoteCharacter = '"';
try {
var x = new sn_impex.CSVParser().parseLineToObject(csvLine, headers, delimiter, quoteCharacter);
}
catch(ex) {
    gs.info(ex.message);
}

Output:

CSVParser: Header list is empty: no thrown error
*** Script: CSVParser: Header list is empty

CTIOperationRequest - Scoped, Global

The CTIOperationRequest API provides methods to set and get data on the current CTIOperationRequest object.

You use CTIOperationRequest objects to pass information between a message transformer and an operation handler within the Cloud Call Center framework.

Typically, a message transformer is responsible for parsing an incoming CTI-specific payload and setting the payload data on an associated CTIOperationRequest object. An operation handler is then responsible for
getting the information from the CTIOperationRequest object and using the
data to process the requested operation.

The ServiceNow base system provides working operation handlers and message
transformers that enable connection to Amazon Connect. When building
contact flows within Amazon Connect, there are two integration points
between Amazon services and a ServiceNow instance:

- Amazon Web Services (AWS) Lambda Proxy (Invoke AWS Lambda function)
- AWS Lex Bot (Get Customer Input)

You can find the available operation handlers and message transformers for
these integration points in the Operation Handlers [sn_cti_operation_handler]
and Provider Message Transformer [sn_cti_provider_msg_transormer] tables.

A payload is passed into a ServiceNow instance from an external source, such
as from a computer telephony integration (CTI) provider that is making an
operation request. When a request is received, a message transformer parses
the payload and uses the CTIOperationRequest set methods to set payload
values, such as the operation handler name, onto an operation and contact-
specific CTIOperationRequest object.

For example, the following message transformer script parses the passed in JSON
payload and sets the values required by the associated operation handler on
the CTIOperationRequest object.

```javascript
{
    try {
        var jsonPayload = httpRequest.body.data;
        if (jsonPayload) {
            var event = jsonPayload.event;
            if (event) {
                var details = event.Details;
                if (details) {
                    operationRequest.setOperationName(details.Parameters['sn_operation']);
                    var contactData = details.ContactData;
                    if(contactData) {
                        // Call Id should be surfaced in openframe call log so it can be tied to transcription
                        later
                        operationRequest.setParameter('contact.call_id', contactData.ContactId);
                        for(var ck in contactData.CustomerEndpoint) {
                            operationRequest.setParameter('contact.' + ck, contactData.CustomerEndpoint[ck]);
                        }
                        operationRequest.setParameter('contact.id', contactData.ContactId);
                        operationRequest.setParameter('contact.phone',
                        contactData.CustomerEndpoint.Address);
```
```javascript
var parameters = details.Parameters;
if (parameters) {
  for (var pk in parameters) {
    switch(pk) {
      case 'interactionId':
        operationRequest.setInteractionSysId(parameters[pk]);
        break;
      case 'authToken':
        operationRequest.setAuthToken(parameters[pk]);
        break;
      case 'language':
        operationRequest.setLanguage(parameters[pk]);
        break;
      default:
        operationRequest.setParameter(pk, parameters[pk]);
    }
  }

  try {
    // Returns the sys_id of the interaction record.
    var interactionSysId = request.getInteractionSysId();
    var number = request.getParameter('number');
    var addComment = request.getParameter('add_comment');
    addComment = addComment ? addComment.toLowerCase() : addComment;
    addComment = 'yes' === addComment || 'true' === addComment || '1' === addComment;

    } catch(e) {
      ctx.setError(e);
    }
  })(httpRequest, operationRequest, ctx);
```

After the message transformer finishes parsing the passed in payload, the Cloud Call Center framework instantiates the specified operation handler. The operating handler uses the `CTIOperationResponse` API get methods to obtain the information that it needs from the associated `CTIOperationRequest` object to process the requested operation.

For example, the following operation handler script stores values that were set on the `CTIOperationRequest` object in the interaction record associated with the call.

```javascript
(function(/*CTIOperationRequest*/ request, /*CTIOperationResponse*/ response, ctx) {

  // Returns the sys_id of the interaction record.
  var interactionSysId = request.getInteractionSysId();
  var number = request.getParameter('number');
  var addComment = request.getParameter('add_comment');
  addComment = addComment ? addComment.toLowerCase() : addComment;
  addComment = 'yes' === addComment || 'true' === addComment || '1' === addComment;

  })(httpRequest, operationRequest, ctx);
```
```javascript
var workNotes = request.getParameter('work_notes');
var message = gs.getMessage('Thankyou');
var interactionGr = request.getInteractionRecord();
var openedFor = interactionGr ? interactionGr.getValue('opened_for') : null;
if (openedFor && number && addComment && workNotes) {
    var now_GR = new GlideRecordSecure('incident');
    now_GR.addQuery('caller_id', openedFor);
    now_GR.addQuery('number', number);
    now_GR.query();
    if (now_GR.next()) {
        now_GR.work_notes += workNotes;
        now_GR.update();
        message = now_GR.getMessage('Your comment was added');
    }
}
response.setStatusCode(200);
response.setMessage(message);
})(request, response, ctx);
```

For additional information on creating operation handlers, see Configure a contact flow for an automated caller interaction.

This API runs in the sn_cti_core namespace. Before you are able to access the CTIOperationRequest API, the Cloud Call Center Core (sn_cti_core) plugin must be activated. For information on activating the Cloud Call Center, see Install Cloud Call Center applications.

For additional information on the Cloud Call Center, see Cloud Call Center.

**CTIOperationRequest - CTIOperationRequest(String origin)**

Instantiates a CTIOperationRequest object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>origin</td>
<td>String</td>
<td>Optional. Origin of the request. Usually the name of the computer telephony integrator provider. Default: null</td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_cti_core.CTIOperationRequest('AWS Connect');
request.setSessionAttribute('contact.phone', '+15552222345');
request.setSessionAttribute('contact.okToCall', true);
request.setSessionAttribute('contact.address', { |
CTIOperationRequest - getAuthToken()

Returns the authentication token set on the associated CTIOperationRequest object.

This token is used by the Cloud Call Center framework to authenticate the current Cloud Call Center user before executing the requested operation handler if the handler's auth_required flag is set to true. The auth_required flag is a field in the Operation Handler [sn_cti_operation_handler] table. The life of an authentication token should be for the life of the call session, but is determined by the CTI provider.

You can define whatever authentication/authorization handling required by your implementation by creating your own authentication operation handler. Regardless of how the authentication token is generated, the message translator must pass the token back in the CTI payload. Additionally, the CTI provider must store this authentication token locally and pass it in each operation request that requires authentication.

If using the instance provided authenticate operation handler, the handler initiates the creation of the authentication token based on a four-digit user-entered pin. It then sets the authentication token in the sessionAttributes object of the CTIOperationResponse object. The associated message transformer translates the sessionAttributes object into the CTI-specific payload and then sends it to the CTI provider.

⚠️ Note: If the authentication token is not passed, all requests to execute operation handlers with the auth_required flag set will fail. If you do not use authentication, you do not need to maintain authentication tokens.

The ServiceNow base system provides working operation handlers and message transformers that enable connection to Amazon Connect. When building contact flows within Amazon Connect, there are two integration points between Amazon services and a ServiceNow instance:

- Amazon Web Services (AWS) Lambda Proxy (Invoke AWS Lambda function)
- AWS Lex Bot (Get Customer Input)

You can find the available operation handlers and message transformers for these integration points in the Operation Handlers [sn_cti_operation_handler] and Provider Message Transformer [sn_cti_provider_msg_transformer] tables.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The authentication token associated with the current Cloud Call Center user.</td>
</tr>
</tbody>
</table>

```javascript
(function( /*CTIProviderResponseExecutionContext*/ ctx, /*CTIOperationRequest*/ operationRequest, /*CTIOperationResponse*/ operationResponse, /*HTTPResponse*/ httpResponse) {
    var sessionAttributes = {},
        intentResponse;
    var statusCode = -1;
    var message = 'Unprocessed';
    if (operationResponse) {
        statusCode = operationResponse.getStatusCode();
        sessionAttributes = operationResponse.getSessionAttributes();
        message = operationResponse.getMessage();
        var error = operationResponse.getError();
        if (error) {
            sessionAttributes.error = error;
        }
    }
    if (sn_cti_core.CTIRequestDispatcher.Constants.HTTP.Status.AUTH_REQUIRED.code === statusCode) {
        // first call for a secure action without authentication token
        sessionAttributes.statusCode = 401;
        sessionAttributes.message = message;
        intentResponse = {
            sessionAttributes,  // Additional session attributes
            dialogAction: {
                type: 'Close',
                fulfillmentState: 'Fulfilled',
                message: {
                    contentType: 'PlainText',
                    content: 'This operation requires authentication. Say authenticate for authentication.'
                }
            }
        }
    }
})(ctx, operationRequest, operationResponse, httpResponse);
```
} else if ('DialogCodeHook' === operationRequest.getParameter('$$invocationSource')) {
    // pass back authToken and interactionId
    sessionAttributes.authToken = operationRequest.getAuthToken();
    sessionAttributes.interactionId = operationRequest.getInteractionSysId();
    var originalSlots = operationRequest.getParameter('$$slots');
    var responseParameters = operationResponse ? operationResponse.getParameters() : {};
    responseParameters = responseParameters ? responseParameters : {};
    // See if processing happened and we got a dialogAction
    var responseDialogAction = responseParameters['dialogAction'];
    // Default dialog action
    var dialogAction = {
        type: 'Delegate',
        slots: originalSlots
    };
    // If the response doesn't contain an override replay the inputs
    if (responseDialogAction) {
        // We bypassed dialoghook so delegate and pass through inputs
        dialogAction = responseDialogAction;
    }
    intentResponse = {
        sessionAttributes: sessionAttributes,
        dialogAction: dialogAction
    };
} else {
    // Override required session attributes
    sessionAttributes.statusCode = statusCode;
    sessionAttributes.message = message;
    // Build response template
    intentResponse = {
        sessionAttributes: sessionAttributes,
        dialogAction: {
            type: 'Close',
            fulfillmentState: 'Fulfilled',
            message: {
                contentType: 'PlainText',
                content: message
            }
        }
    };
}
CTIOperationRequest - getInteractionRecord()

Returns the interaction GlideRecord associated with the operation request.

An interaction represents a customer request for assistance made through a chat, phone call, or in-person. Interactions can be routed to queues for assignment or assigned to agents directly. Interaction records are stored in the Interaction [interaction] table and can contain any type of data that describes service account interactions with a customer for a specific session.

Interaction records are associated with a CTIOperationRequest object through the CTIOperationRequest - setInteractionSysId(String Id) method. This method is typically called by the message transformer and must be called prior to calling the getInteractionRecord() method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>Interaction GlideRecord object associated with the current CTIOperationRequest object. If the interaction record sys_id has not been set on the CTIOperationRequest object, returns null.</td>
</tr>
</tbody>
</table>

```javascript
(function(/*CTIOperationRequest*/ request, /*CTIOperationResponse*/ response, /*Context*/ ctx) {
    var notes = '', lang = request.getLanguage();
    try {
        // Returns the interaction record (GlideRecord) set on the passed in CTIOperationRequest object
        var interactionGr = request.getInteractionRecord();

        var now_GR = new GlideRecord('sys_user');
        if(interactionGr && now_GR.get(interactionGr.opened_for.toString())) {
            if(now_GR.locked_out == true) {
                notes += gs.getMessageLang("User record found locked. Unlocking the account.
```
now_GR.locked_out=false;
now_GR.update();
response.setStatusCode(200);
response.setMessage(gs.getMessageLang("Your account has been unlocked.", lang));
} else {
    notes += gs.getMessageLang("User record not locked.
", lang);
    response.setStatusCode(200);
    response.setMessage(gs.getMessageLang("Your account doesn't seem to be locked.", lang));
}
} else {
    notes += gs.getMessageLang("User record not found. Transfer to agent
", lang);
    response.setStatusCode(302);
    response.setMessage(gs.getMessageLang("I am unable to find your record. Let me
transfer to someone who can help.", lang));
}
if(interactionGr) {
    interactionGr.work_notes = notes;
    interactionGr.update();
}
} catch(e) {
    ctx.setError(e);
}
})(request, response, ctx);

**CTIOperationRequest - getInteractionSysId()**

Returns the sys_id of the interaction record associated with the current CTIOperationRequest object.

The **CTIOperationRequest - setInteractionSysId(String Id)** method must have been called prior to calling this method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The sys_id of the interaction record set on the current CTIOperationRequest object.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the sys_id was not set on the associated CTIOperationRequest object, the method returns null.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
(function( /*CTIOperationRequest*/ request, /*CTIOperationResponse*/ response, ctx) {
    // Returns the sys_id of the interaction record associated with the CTIOperationRequest object.
    var interactionSysId = request.getInteractionSysId();
    var number = request.getParameter('number');
    var addComment = request.getParameter('add_comment');
    addComment = addComment.toLowerCase() || addComment || '1';
    var workNotes = request.getParameter('work_notes');
    var message = gs.getMessage('Thankyou');
    var interactionGr = request.getInteractionRecord();
    var openedFor = interactionGr ? interactionGr.getValue('opened_for') : null;
    if (openedFor && number && addComment && workNotes) {
        var now_GR = new GlideRecordSecure('incident');
        now_GR.addQuery('caller_id', openedFor);
        now_GR.addQuery('number', number);
        now_GR.query();
        if (now_GR.next()) {
            now_GR.work_notes += workNotes;
            now_GR.update();
            message = gs.getMessage('Your comment was added');
        }
    }
    response.setStatusCode(200);
    response.setMessage(message);
})(request, response, ctx);
```

**CTIOperationRequest - getLanguage()**

Returns the ISO 639.1 language code that was set on the current CTIOperationRequest object.

Using the customer preferred language enables you to use platform-provided internationalization and localization capabilities to customize messages and other communications with the associated caller.
Typically an operation handler calls the `getLanguage()` method and the message transformer sets the language on the CTIOperationRequest object by calling the `CTIOperationRequest - setLanguage(String languageCode)` method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The ISO 639.1 language code set on the current CTIOperationRequest object. If the language code is not set, returns <code>en</code>.</td>
</tr>
</tbody>
</table>

The following example shows an operation handler calling `getLanguage()` to obtain the caller's preferred language.

```javascript
(function(/*CTIOperationRequest*/ request, /*CTIOperationResponse*/ response) {
    // Obtain the contact's preferred language
    var notes = "", announcement, lang = request.getLanguage();
    try {
        var interactionGr = request.getInteractionRecord();

        announcement = gs.getMessageLang("We are currently experiencing issues with VPN. If you are calling about VPN issues, you may hang up the call.", lang);
        // Use the contact's language to customize the response messages and notes
        if(announcement) {
            notes = gs.getMessageLang("Listened to announcement: {0}", lang, [announcement]);
            response.setStatusCode(200);
        } else {
            announcement = gs.getMessageLang("There are currently no known outage announcements", lang);
            // use the status case as the flag to check for announcements in contact flow
            response.setStatusCode(404);
        }
        response.setMessage(announcement);

        if(interactionGr & notes) {
            interactionGr.work_notes = notes;
            interactionGr.update();
        }
    }
});
```
CTIOperationRequest - getMajorVersion()

Returns the major version of the computer telephony integrator (CTI) software set on the current CTIOperationRequest object.

Use this method if the CTI providers connected to your ServiceNow instance are running multiple versions of their software, as different software versions may require different processing behavior. If the processing behavior is only slightly different between the software versions, it may make sense to have only a single operation handler. You can then handle the processing differences by just checking the version of software making the request and process the request/data within your operation handler. If the required processing is significantly different between versions, it may be more effective to use multiple operation handlers.

Typically the message transformer sets the software version on the CTIOperationRequest object by calling the CTIOperationRequest - setMajorVersion(Number majorVersion) method and an operation handler then consumes the set value using this method. You can also get/set the minor version value of a provider's software using the CTIOperationRequest - getMinorVersion() and CTIOperationRequest - setMinorVersion(Number minorVersion) methods.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Number| Major version number of the CTI software.  
If the major version was never set, returns 1. |
var request = new sn_cti_core.CTIOperationRequest('origin');
var majorVersion = request.getMajorVersion();

**CTIOperationRequest - getMinorVersion()**

Returns the minor version of the computer telephony integrator (CTI) software associated with a CTIOperationRequest object.

Use this method if the CTI providers connected to your ServiceNow instance are running multiple versions of their software, as different software versions may require different processing behavior. If the processing behavior is only slightly different between the software versions, it may make sense to have only a single operation handler. You can then handle the processing differences by just checking the version of software making the request and process the request/data within your operation handler. If the required processing is significantly different between versions, it may be more effective to use multiple operation handlers.

Typically the message transformer sets the software version on the CTIOperationRequest object by calling the `CTIOperationRequest - setMinorVersion(Number minorVersion)` method and an operation handler then consumes the set value using this method. You can also get/set the major version value of a provider's software using the `CTIOperationRequest - getMajorVersion()` and `CTIOperationRequest - setMajorVersion(Number majorVersion)` methods.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Minor version number of the CTI software.</td>
</tr>
<tr>
<td></td>
<td>If the minor version was never set, returns 0.</td>
</tr>
</tbody>
</table>

var request = new sn_cti_core.CTIOperationRequest('origin');
var minorVersion = request.getMinorVersion();
CTIOperationRequest - getOperationName()

Returns the name of the operation that the computer telephony integration (CTI) provider is requesting to execute.

The operation name determines the operation handler that is used to process a request. Typically the message transformer sets the operation name on the CTIOperationRequest object using the CTIOperationRequest - setOperationName(String name) method.

**Note:** The getOperationName() method does not instantiate the associated operation handler. This is done by the Cloud Call Center framework. This method simply returns the associated operation handler name.

**Note:** For Amazon Connect Lex Bot implementations, intent names are appended with a five letter suffix as different Amazon intents cannot have the same intent name. In the Cloud Call Center framework, the intent name equals the operation handler name. An operation handler can either be specific for an intent, having an operation handler name that includes this suffix (myOperation_SUFFX), or it can be generic and used by multiple CTI providers or different use cases, such as using the same handler for processing an HR request and a helpdesk request (myOperation).

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_citi_core.CTIOperationRequest('origin');
var name = request.getOperationName();
```

CTIOperationRequest - getOperationSubStepName()

Returns the substep operation handler name set on the current CTIOperationRequest object.

Use substeps to perform actions such as initialization and validation before processing an operation. Unlike operation handlers that are meant to be
generic and used by all CTI providers, substeps are CTI provider specific and use terminology and naming conventions that are specific to the CTI provider.

The Cloud Call Center framework performs the following steps to locate the required operation handler and any associated substep operation handlers.

1. Tries to locate the operation handler associated with the request.
   - First checks for an operation handler called `myOperation_SUFFX`.
   - If not found, checks for the operation handler `myOperation`. If not found, errors out.

2. If the handler is found, checks the `auth_required` flag on the operation handler. If set, it checks that a valid authentication token (obtained through the `getAuthToken()` method) is present on the request. If present and valid, continue processing, else throw an error.

3. Looks up the operation handler for the passed in substep. For this example let's assume `subStepName=SubStep`.
   - First checks for an operation handler named `myOperation_SUFFX.SubStep`. If found, executes the handler.
   - If not found, checks for the handler `myOperation.SubStep`. If found executes the handler.
   - If not found, checks if a `subStepNotFoundBehavior` was set on the request object.
     - If set, executes the behavior, otherwise, errors out.

4. Executes the primary operation handler (`myOperation_SUFFX` or `myOperation`).

Typically the message transformer sets the substep name on the CTIOperationRequest object using the `CTIOperationRequest - setOperationSubStepName(String name)` method. You can override this behavior if you are creating your own transformer by calling the `CTIOperationRequest - setSubStepNotFoundBehaviour(Object behaviour)` method.

Note: For Amazon Connect Lex Bot implementations, intent names are appended with a five letter suffix as different Amazon intents cannot have the same intent name. In the Cloud Call Center framework, the intent name equals the operation handler name. An operation handler can either be specific for an intent, having an operation handler name that includes this suffix (myOperation_SUFFX), or it can be generic and used by multiple CTI providers or different use cases, such as using the same handler for processing an HR request and a helpdesk request (myOperation).
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The name of the substep operation handler set on the CTIOperationRequest object. If it does not exist, returns null.</td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_cti_core.CTIOperationRequest('origin');
var name = request.getOperationSubStepName();
```

#### CTIOperationRequest - getParameter(String key)

Returns the value of a specified key previously set on the current CTIOperationRequest object.

Using the get/set parameter methods enables the passing of virtually any string or number value between a message transformer and an operation handler. The parameter object can contain zero or more key/value pairs of data that directly correlate to the current operation request. The operation handler determines what key/value pairs are required as it consumes these values. Typically the message transformer sets these parameters on the CTIOperationRequest object by calling the `setParameter(String key, Object value)` method and the operation handler consumes them using this method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>The name of the key value to return.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String or Number</td>
<td>Value of the specified key. If no such key exists, returns null.</td>
</tr>
</tbody>
</table>
function(/*CTIOperationRequest*/ request, /*CTIOperationResponse*/ response, ctx) {
    var interactionSysId = request.getInteractionSysId();
    // Returns the number and add_comments parameters from the CTIOperationRequest object
    var number = request.getParameter('number');
    var addComment = request.getParameter('add_comment');
    addComment = addComment ? addComment.toLowerCase() : addComment;
    addComment = 'yes' === addComment || 'true' === addComment || '1' === addComment;
    var workNotes = request.getParameter('work_notes');
    var message = gs.getMessage('Thankyou');
    var interactionGr = request.getInteractionRecord();
    var openedFor = interactionGr ? interactionGr.getValue('opened_for') : null;
    if (openedFor && number && addComment && workNotes) {
        var now_GR = new GlideRecordSecure('incident');
        now_GR.addQuery('caller_id', openedFor);
        now_GR.addQuery('number', number);
        now_GR.query();
        if (now_GR.next()) {
            now_GR.work_notes += workNotes;
            now_GR.update();
            message = gs.getMessage('Your comment was added');
        }
    }
    response.setStatusCode(200);
    response.setMessage(message);
})(request, response, ctx);

CTIOperationRequest - getParameters()

Returns the key-value pairs for all parameters that were previously set on the current CTIOperationRequest object.

Using the get/set parameter methods enables the passing of virtually any string or number value between a message transformer and an operation handler. The parameter object can contain zero or more key/value pairs of data that directly correlate to the current operation request. The operation handler determines what key/value pairs are required as it consumes these values. Typically, the message transformer sets these parameters on the CTIOperationRequest object by calling the CTIOperationRequest - setParameter(String key, Object value) method and the operation handler consumes them using this method.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>A map of key-value pairs that were previously set on the CTIOperationRequest object. This key-value pairs are free-form and defined by the needs of the operation handler. The returned values are either Strings or Numbers.</td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_cti_core.CTIOperationRequest('origin');
var parms = request.getParameters();
for(var key in parms) {
    gs.info(key + '=' + parms[key]);
}
```

**CTIOperationRequest - getSessionAttribute(String key)**

Returns the value of a specified session attribute key set on the current CTIOperationRequest object.

Using the get/set session attribute methods enables the passing of virtually any string or number value between a message transformer and an operation handler. The sessionAttribute object can contain zero or more key/value pairs of data that are valid for the duration of a computer telephony integration provider defined session, such as the contact's phone number. Session attributes can also be accessed within a contact flow. The operation handler determines what session attribute key/value pairs are needed as it consumes these values. Typically the message transformer sets these attributes on the CTIOperationRequest object by calling the **CTIOperationRequest - setSessionAttribute(String key, Object value)** method. Session attributes are different than parameters in that they persist for the life of the session (such as the entire call) and should be passed back by the CTI provider with each operation request within that call session.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>The name of the key value to return.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String or Number</td>
<td>Value of the specified key. If no such key exists, returns null.</td>
</tr>
</tbody>
</table>

```
var request = new sn_cti_core.CTIOperationRequest('origin');
var phoneAttribute = request.getSessionAttribute('contact.phone');
```

**CTIOperationRequest - getSessionAttributes()**

Returns a key-value pair map of all session attributes set on the current CTIOperationRequest object.

Using the get/set session attribute methods enables the passing of virtually any string or number value between a message transformer and an operation handler. The sessionAttribute object can contain zero or more key/value pairs of data that are valid for the duration of a computer telephony integration provider defined session, such as the contact's phone number. Session attributes can also be accessed within a contact flow. The operation handler determines what session attribute key/value pairs are needed as it consumes these values. Typically the message transformer sets these attributes on the CTIOperationRequest object by calling the `CTIOperationRequest - setSessionAttribute(String key, Object value)` method. Session attributes are different than parameters in that they persist for the life of the session (such as the entire call) and should be passed back by the CTI provider with each operation request within that call session.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>A map of session attribute key-value pairs that were set on the associated CTIOperationResponse object. This map is free-form and defined by the needs of the operation handler.</td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_cti_core.CTIOperationRequest('origin');
var parms = request.getSessionAttributes();
for(var key in parms) {
  gs.info(key + '=' + parms[key]);
}
```

CTIOperationRequest - getSubStepNotFoundBehaviour

Returns the handling behavior for a subsep when a substep's operation handler is not found.

Use substeps to perform actions such as initialization and validation before processing an operation. Unlike operation handlers that are meant to be generic and used by all CTI providers, substeps are CTI provider specific and use terminology and naming conventions that are specific to the CTI provider.

If the requested substep operation handler cannot be found by the Cloud Call Center framework, it attempts to use the "step not found behavior". This behavior is typically set by the message transformer when an operation is initially requested.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OperationNotFoundBehaviours</td>
<td>The behavior/handling to perform when an operation handler cannot be found for the operation/substep combination (&lt;operation_name&gt;.SubStep&gt;). If not defined, returns null. Possible values:</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• OperationNotFoundBehaviours.PassThrough: Do not perform any further processing on the request, just return.</td>
</tr>
<tr>
<td></td>
<td>• OperationNotFoundBehaviours.RouteToOperation: Use the parent operation handler &lt;operation_name&gt;.</td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_cti_core.CTIOperationRequest('origin');
var behavior = request.getSubStepNotFoundBehaviour();
```

**CTIOperationRequest - setAuthToken(String id)**

Sets an authentication token on the current CTIOperationRequest object.

This token is used by the Cloud Call Center framework to authenticate the current Cloud Call Center user before executing the requested operation handler if the handler's `auth_required` flag is set to true. The `auth_required` flag is a field in the Operation Handler [sn_cti_operation_handler] table. The life of an authentication token should be for the life of the call session, but is determined by the CTI provider.

You can define whatever authentication/authorization handling required by your implementation by creating your own authentication operation handler. Regardless of how the authentication token is generated, the message translator must pass the token back in the CTI payload. Additionally, the CTI provider must store this authentication token locally and pass it in each operation request that requires authentication.

If using the instance provided authenticate operation handler, the handler initiates the creation of the authentication token based on a four-digit user-entered pin. It then sets the authentication token in the sessionAttributes object of the CTIOperationResponse object. The associated message transformer translates the sessionAttributes object into the CTI-specific payload and then sends it to the CTI provider.

⚠️ **Note:** If the authentication token is not passed, all requests to execute operation handlers with the `auth_required` flag set will fail. If you do not use authentication, you do not need to maintain authentication tokens.
The ServiceNow base system provides working operation handlers and message transformers that enable connection to Amazon Connect. When building contact flows within Amazon Connect, there are two integration points between Amazon services and a ServiceNow instance:

- Amazon Web Services (AWS) Lambda Proxy (Invoke AWS Lambda function)
- AWS Lex Bot (Get Customer Input)

You can find the available operation handlers and message transformers for these integration points in the Operation Handlers [sn_cti_operation_handler] and Provider Message Transformer [sn_cti_provider_msg_transormer] tables.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>The authentication token for the associated Cloud Call Center user.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example of message transformer script that saves the passed in authentication token.

```javascript
{
  try {
    var jsonPayload = httpRequest.body.data;
    if (jsonPayload) {
      var event = jsonPayload.event;
      if (event) {
        var details = event.Details;
        if (details) {
          operationRequest.setOperationName(details.Parameters['sn_operation']);
          var contactData = details.ContactData;
          if(contactData) {
            // Call id should be surfaced in openframe call log so it can be tied to transcription later
            operationRequest.setParameter('contact.call_id', contactData.ContactId);
            for(var ck in contactData.CustomerEndpoint) {
              operationRequest.setParameter('contact.' + ck, contactData.CustomerEndpoint[ck]);
            }
          }
        }
      }
    }
  }
}
```
operationRequest.setParameter('contact.id', contactData.ContactId);
operationRequest.setParameter('contact.phone',
contactData.CustomerEndpoint.Address);

var parameters = details.Parameters;
if (parameters) {
  for (var pk in parameters) {
    switch(pk) {
      case 'interactionId':
        operationRequest.setInteractionSysId(parameters[pk]);
        break;
      case 'authToken':
        operationRequest.setAuthToken(parameters[pk]);
        break;
      case 'language':
        operationRequest.setLanguage(parameters[pk]);
        break;
      case 'statusCode':
        case 'message':
        break;
      default:
        operationRequest.setParameter(pk, parameters[pk]);
    }
  }
}

try {
  (httpRequest, operationRequest, ctx);
}

} catch(e) {
  ctx.setError(e);
}

CTIOperationRequest - setInteractionSysId(String Id)
Sets the sys_id of the interaction record associated with the operation request on the current CTIOperationRequest object.

If you want to maintain contact interaction information within a contact-specific interaction record, the interaction record sys_id must be maintained for the entire Cloud Call Center call session.

Typically, an operation handler creates an interaction record when a new contact call is initiated. It then sets the interaction record sys_id and table name
on the associated CTIOperationResponse object as session attributes using the
CTIOperationResponse - setSessionAttribute(String key, Object value) method.
The associated method transformer then translates this information into the
computer telephony integration (CTI) provider payload and sends it back to the
CTI provider.

The CTI provider must store the interaction record sys_id for the contact session
locally. Each time the CTI provider interacts with the Cloud Call Center for this
contact session, it must pass back the corresponding interaction record sys_id
in its payload. The receiving message transformer then parses the payload
and uses the CTIOperationRequest - setInteractionSysId() method to set the
interaction record sys_id on the associated CTIOperationRequest object.

The CTIOperationRequest - getInteractionRecord() method uses this sys_id to
obtain the correct interaction record for the contact session. Interaction records
are located in the Interaction [interaction] table. For additional information on
interaction records, see

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>String</td>
<td>The sys_id of the interaction record to associate with the request.</td>
</tr>
</tbody>
</table>

Example of a message transformer script that extracts the interaction record
sys_id from the incoming payload (passed as a parameter) and sets it on the
associated CTIOperationRequest object.

```java
{ 
  try {
    var jsonPayload = httpRequest.body.data;
    if (jsonPayload) {
      var event = jsonPayload.event;
      if (event) {
        var details = event.Details;
        if (details) {
          operationRequest.setOperationName(details.Parameters['sn_operation']);
          var contactData = details.ContactData;
          if(contactData) {
```

// Call id should be surfaced in openframe call log so it can be tied to transcription later
operationRequest.setParameter('contact.call_id', contactData.ContactId);
for(var ck in contactData.CustomerEndpoint) {
    operationRequest.setParameter('contact.' + ck, contactData.CustomerEndpoint[ck]);
}
operationRequest.setParameter('contact.id', contactData.ContactId);
operationRequest.setParameter('contact.phone', contactData.CustomerEndpoint.Address);
}
var parameters = details.Parameters;
if (parameters) {
    for (var pk in parameters) {
        switch(pk) {
            // Associate the existing customer interaction record with the request
            case 'interactionId':
                operationRequest.setInteractionSysId(parameters[pk]);
                break;
            case 'authToken':
                operationRequest.setAuthToken(parameters[pk]);
                break;
            case 'language':
                operationRequest.setLanguage(parameters[pk]);
                break;
            case 'statusCode':
            case 'message':
                break;
        
        default:
            operationRequest.setParameter(pk, parameters[pk]);
        }
    }
} catch(e) {
    ctx.setError(e);
}())(httpRequest, operationRequest, ctx);
CTIOperationRequest - setLanguage(String languageCode)

Sets the ISO 639.1 language code to use when processing the associated operation on a CTIOperationRequest object.

Using the customer preferred language enables you to use platform-provided internationalization and localization capabilities to customize messages and other communications with the associated caller. Typically the message transformer sets the language on the CTIOperationRequest object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>languageCode</td>
<td>String</td>
<td>The ISO 639.1 language code to use when processing the associated operation.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
{
    try {
        var jsonPayload = httpRequest.body.data;
        if (jsonPayload) {
            var event = jsonPayload.event;
            if (event) {
                var details = event.Details;
                if (details) {
                    operationRequest.setOperationName(details.Parameters['sn_operation']);
                    var contactData = details.ContactData;
                    if (contactData) {
                        // Call id should be surfaced in openframe call log so it can be tied to transcription later
                        operationRequest.setParameter('contact.call_id', contactData.ContactId);
                        for (var ck in contactData.CustomerEndpoint) {
                            operationRequest.setParameter('contact.' + ck, contactData.CustomerEndpoint[ck]);
                        }
                        operationRequest.setParameter('contact.id', contactData>ContactData.ContactId);
                        operationRequest.setParameter('contact.phone', contactData.CustomerEndpoint.Address);
                    }
                }
            }
        }
    }
    catch (error) {
        console.error(error);
    }
}
```
var parameters = details.Parameters;
if (parameters) {
  for (var pk in parameters) {
    switch(pk) {
      case 'interactionId':
        operationRequest.setInteractionSysId(parameters[pk]);
        break;
      case 'authToken':
        operationRequest.setAuthToken(parameters[pk]);
        break;
      case 'language':
        operationRequest.setLanguage(parameters[pk]);
        break;
      case 'statusCode':
      case 'message':
        break;
      default:
        operationRequest.setParameter(pk, parameters[pk]);
    }
  }
} catch(e) {
  ctx.setError(e);
}
})(httpRequest, operationRequest, ctx);

CTIOperationRequest - setMajorVersion(Number majorVersion)

Sets the major version of the computer telephony integrator (CTI) provider software making the request on the associated CTIOperationRequest object.

Use this method if the CTI providers connected to your ServiceNow instance are running multiple versions of their software, as different software versions may require different processing behavior. If the processing behavior is only slightly different between the software versions, it may make sense to have only a single operation handler. You can then handle the processing differences by just checking the version of software making the request and process the request/data within your operation handler. If the required processing is significantly different between versions, it may be more effective to use multiple operation handlers.
Typically the message transformer sets the software version on the CTIOperationRequest object by calling this method and an operation handler then consumes the set value using the CTIOperationRequest - getMajorVersion() method. You can also get/set the minor version value of a provider's software using the CTIOperationRequest - getMinorVersion() and CTIOperationRequest - setMinorVersion(Number minorVersion) methods.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>majorVersion</td>
<td>Number</td>
<td>Major version of the CTI provider software making the operation request.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If this value was not previously set, returns 1.</td>
</tr>
</tbody>
</table>

```
var request = new sn_cti_core.CTIOperationRequest('origin');
request.setMajorVersion(2);
```

**CTIOperationRequest - setMinorVersion(Number minorVersion)**

Sets the minor version of the computer telephony integrator (CTI) provider software making the request on the associated CTIOperationRequest object.

Use this method if the CTI providers connected to your ServiceNow instance are running multiple versions of their software, as different software versions may require different processing behavior. If the processing behavior is only slightly different between the software versions, it may make sense to have only a single operation handler. You can then handle the processing differences by just checking the version of software making the request and process the request/data within your operation handler. If the required processing is significantly different between versions, it may be more effective to use multiple operation handlers.

Typically the message transformer sets the software version on the CTIOperationRequest object by calling this method and an operation handler then consumes the set value using the CTIOperationRequest - getMinorVersion() method. You can also get/set the major version value of a provider's software using the CTIOperationRequest - getMajorVersion() and CTIOperationRequest - setMajorVersion(Number majorVersion) methods.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>minorVersion</td>
<td>Number</td>
<td>Minor version of the CTI provider software making the operation request. If this value was not previously set, returns 0.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_cti_core.CTIOperationRequest('origin');
...
request.setMinorVersion(3);
```

### `CTIOperationRequest - setOperationName(String name)`

Sets the name of the operation that the computer telephony integration (CTI) provider is attempting to execute on the current CTIOperationRequest object.

The operation name determines the operation handler that is used to process the request. Call this method from the associated message transformer.

**Note:** For Amazon Connect Lex Bot implementations, intent names are appended with a five letter suffix as different Amazon intents cannot have the same intent name. In the Cloud Call Center framework, the intent name equals the operation handler name. An operation handler can either be specific for an intent, having an operation handler name that includes this suffix (myOperation_SUFFX), or it can be generic and used by multiple CTI providers or different use cases, such as using the same handler for processing an HR request and a helpdesk request (myOperation).

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the operation that the CTI provider is currently attempting to execute. This name must be the same as the name of the operation handler to use to process the request. If it is not, an error is</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>thrown. You can locate the available operation handlers in the Operation Handler [sn_cti_operation_handler] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
break;
case 'language':
operationRequest.setLanguage(parameters[pk]);
break;
case 'statusCode':
case 'message':
break;

default:
operationRequest.setParameter(pk, parameters[pk]);
}
}
}
}
}
) catch(e) {
ctx.setError(e);
}
})(httpRequest, operationRequest, ctx);

CTIOperationRequest - setOperationSubStepName(String name)

Sets the operation substep name on the current CTIOperationRequest object.

Use substeps to perform actions such as initialization and validation before processing an operation. Unlike operation handlers that are meant to be generic and used by all CTI providers, substeps are CTI provider specific and use terminology and naming conventions that are specific to the CTI provider.

The Cloud Call Center framework performs the following steps to locate the required operation handler and any associated substep operation handlers.

⚠️ Note: For Amazon Connect Lex Bot implementations, intent names are appended with a five letter suffix as different Amazon intents cannot have the same intent name. In the Cloud Call Center framework, the intent name equals the operation handler name. An operation handler can either be specific for an intent, having an operation handler name that includes this suffix (myOperation_SUFFX), or it can be generic and used by multiple CTI providers or different use cases, such as using the same handler for processing an HR request and a helpdesk request (myOperation).
1. Tries to locate the operation handler associated with the request.
   • First checks for an operation handler called `myOperation_SUFFIX`.
   • If not found, checks for the operation handler `myOperation`. If not found, errors out.

2. If the handler is found, checks the `auth_required` flag on the operation handler. If set, it checks that a valid authentication token (obtained through the `getAuthToken()` method) is present on the request. If present and valid, continue processing, else throw an error.

3. Looks up the operation handler for the passed in substep. For this example let's assume `subStepName=SubStep`.
   • First checks for an operation handler named `myOperation_SUFFIX.SubStep`. If found, executes the handler.
   • If not found, checks for the handler `myOperation.SubStep`. If found executes the handler.
   • If not found, checks if a `subStepNotFoundBehavior` was set on the request object.
   • If set, executes the behavior, otherwise, errors out.

4. Executes the primary operation handler (`myOperation_SUFFIX` or `myOperation`.)

You can set the default behavior of a substep by calling the `CTIOperationRequest - setSubStepNotFoundBehaviour(Object behaviour)` method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the substep that the CTI provider is trying to execute.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
(function( /*HTTPRequest*/ httpRequest, /*CTIOperationRequest*/ operationRequest, /*Context*/ ctx) {
  try {
    var jsonPayload = httpRequest.body.data;
```
if (jsonPayload) {
    var event = jsonPayload.event;
    if (event) {
        var intent = event.currentIntent;
    var inputTranscript = event.inputTranscript;
    if (inputTranscript) {
        operationRequest.setParameter('$utterance', inputTranscript);
    }
    if (intent) {
        operationRequest.setOperationName(intent.name);
        // Add this because intent name gets changed through the pipeline
        operationRequest.setParameter('$original_intent', intent.name);
        var sessionAttributes = event.sessionAttributes;
        if (sessionAttributes) {
            for (var sk in sessionAttributes) {
                switch (sk) {
                    case 'interactionId':
                        operationRequest.setInteractionSysId(sessionAttributes[sk]);
                        break;
                    case 'authToken':
                        operationRequest.setAuthToken(sessionAttributes[sk]);
                        break;
                    case 'language':
                        operationRequest.setLanguage(sessionAttributes[sk]);
                        break;
                    case 'statusCode':
                    case 'message':
                        break;
                    default:
                        operationRequest.setSessionAttribute(sk, sessionAttributes[sk]);
                        break;
                }
            }
        }
        var slots = intent.slots;
        // Always copy in slots they are the parameters for the operation
        if (slots) {
            for (var pk in slots) {
                operationRequest.setParameter(pk, slots[pk]);
            }
        }
    var invocationSource = event.invocationSource;
    operationRequest.setParameter('$$invocationSource', invocationSource);
    // Specific handling for dialog hooks with a way to override for Amazon specific provider
    }
if (invocationSource === 'DialogCodeHook') {
    // Set substep to trigger forwarding to another handler IF it s present
    operationRequest.setOperationSubStepName(invocationSource);
    // Allow pass through behavior
    var behaviourToUse =
        sn_cti_core.CTIOperationRequest.OperationNotFoundBehaviours.PassThrough;
    operationRequest.setSubStepNotFoundBehaviour(behaviourToUse);
    // Reserved - copy slots in so we can just use delegate as default if the call isn't handled
    operationRequest.setParameter('$$slots', slots);
}

} catch (e) {
    ctx.setError(e);
}
return operationRequest;

CTIOperationRequest - setParameter(String key, Object value)
Sets the specified key-value pair on the parameter object of the current CTIOperationRequest object.

Using the get/set parameter methods enables the passing of virtually any string or number value between a message transformer and an operation handler. The parameter object can contain zero or more key/value pairs of data that directly correlate to the current operation request. The operation handler determines what key/value pairs are required as it consumes these values. Typically the message transformer sets these parameters on the CTIOperationRequest object by calling this method and the operation handler consumes them using the CTIOperationRequest - getParameter(String key) or CTIOperationRequest - getParameters() method.

⚠️ **Note:** You should only store objects that can survive a JSON.parse(JSON.stringify(object)) operation. Objects not meeting this criteria may not propagate correctly through the entire operation processing chain.

For example:

```javascript
var x = {
    "string": 'abc',
    "int": 123,
};
```
```javascript
"float": 1.234,
"number": new Number(3),
"boolean": true,
"date": new Date(2006, 0, 2, 15, 4, 5),
"object": {
  "string": 'abc',
  "int": 123,
  "float": 1.234,
  "number": new Number(3),
  "boolean": true,
  "date": new Date(2006, 0, 2, 15, 4, 5)
},
"function": function(abc) {
  console.log(abc);
}
}
var stringify = JSON.stringify(x);
gs.info(stringify);
var hydrate = JSON.parse(stringify);
var stringify2 = JSON.stringify(hydrate);
gs.info(stringify2);
```

Produces:

```javascript
```

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>

default:
    operationRequest.setParameter(pk, parameters[pk]);
}
```

### CTIOperationRequest - `setSessionAttribute(String key, Object value)`

Sets the specified session attribute key-value pair on the current CTIOperationRequest object.

Using the get/set session attribute methods enables the passing of virtually any string or number value between a message transformer and an operation handler. The `sessionAttribute` object can contain zero or more key/value pairs of data that are valid for the duration of a computer telephony integration provider defined session. Session attributes can also be accessed within a contact flow. The operation handler determines what session attribute key/value pairs are needed as it consumes these values. Typically the message transformer sets these attributes on the CTIOperationRequest object by calling this method and the operation handler gets the attributes using the `CTIOperationRequest - getSessionAttribute(String key)` or `CTIOperationRequest - getSessionAttributes()` method.

**Note:** You should only store objects that can survive a `JSON.parse(JSON.stringify(object))` operation. Objects not meeting this criteria may not propagate correctly through the entire operation processing chain.
For example:

```javascript
var x = {
    "string": 'abc',
    "int": 123,
    "float": 1.234,
    "number": new Number(3),
    "boolean": true,
    "date": new Date(2006, 0, 2, 15, 4, 5),
    "object": {
        "string": 'abc',
        "int": 123,
        "float": 1.234,
        "number": new Number(3),
        "boolean": true,
        "date": new Date(2006, 0, 2, 15, 4, 5)
    },
    "function": function(abc) {
    }
};

var stringify = JSON.stringify(x);
gs.info(stringify);
var hydrate = JSON.parse(stringify);
var stringify2 = JSON.stringify(hydrate);
gs.info(stringify2);
```

Produces:

```
```

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Name of the key under which to store the associated value.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>Value to store.</td>
</tr>
</tbody>
</table>

Valid data types:
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>• string</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• int</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• float</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• number</td>
</tr>
<tr>
<td></td>
<td></td>

</tr>
<tr>
<td></td>
<td></td>
<td>• date</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• object</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_cti_core.CTIOperationRequest('origin');
request.setSessionAttribute('contact.phone', '+15552222345');
request.setSessionAttribute('contact.okToCall', true);
request.setSessionAttribute('contact.address', {
    street: '1234 Main St'
    city: 'API City',
    zip: 91335
});
```

CTIOperationRequest - setSubStepNotFoundBehaviour(Object behaviour)

Sets the behavior to perform if the current substep's operation handler is not found.

This method should be called by the input message transformer.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| behaviour  | OperationNotFoundBehaviours | Behavior to use if a handling behavior is not specified for the substep. This must be a behavior defined on the
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| CTIOperationRequest.OperationNotFoundBehaviours | object | Possible values:  
  • ThrowError: Throw an error.  
  • PassThrough: Do not perform any further processing on the request, just return.  
  • RouteToOperation: Use the parent operation handler `<operation_name>`.

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
(function (/*HTTPRequest*/ httpRequest, /*CTIOperationRequest*/ operationRequest, /*Context*/ ctx) {
  try {
    var jsonPayload = httpRequest.body.data;
    if (jsonPayload) {
      var event = jsonPayload.event;
      if (event) {
        var intent = event.currentIntent;
        var inputTranscript = event.inputTranscript;
        if (inputTranscript) {
          operationRequest.setParameter('utterance', inputTranscript);
        }
        if (intent) {
          operationRequest.setOperationName(intent.name);
          // Add this because intent name gets changed through the pipeline
          operationRequest.setParameter('original_intent', intent.name);
          var sessionAttributes = event.sessionAttributes;
          if (sessionAttributes) {
            for (var sk in sessionAttributes) {
              switch (sk) {
                case 'interactionId':
                  operationRequest.setInteractionSysId(sessionAttributes[sk]);
                  break;
              }
            }
          }
        }
      }
    }
  }
});
```
case 'authToken':
    operationRequest.setAuthToken(sessionAttributes[sk]);
    break;

case 'language':
    operationRequest.setLanguage(sessionAttributes[sk]);
    break;

    case 'status':
    case 'message':
        break;

    default:
        operationRequest.setSessionAttribute(sk, sessionAttributes[sk]);
        break;

var slots = intent.slots;
// Always copy in slots they are the parameters for the operation
if (slots) {
    for (var pk in slots) {
        operationRequest.setParameter(pk, slots[pk]);
    }
}

var invocationSource = event.invocationSource;
operationRequest.setParameter('$$invocationSource', invocationSource);
// Specific handling for dialog hooks with a way to override for Amazon specific
provider
    if (invocationSource === 'DialogCodeHook') {
        // Set substep to trigger forwarding to another handler IF it s present
        operationRequest.setOperationSubStepName(invocationSource);
        // Allow pass through behavior
        var behaviourToUse = sn_cti_core.CTIOperationRequest.OperationNotFoundBehaviours.PassThrough;
        operationRequest.setSubStepNotFoundBehaviour(behaviourToUse);
        // Reserved - copy slots in so we can just use delegate as default if the call isn't
        handled
        operationRequest.setParameter('$$slots', slots);
    }
}

try {
    // Act
}

} catch (e) {
    ctx.setError(e);
}
CTIOperationResponse - Scoped, Global

The CTIOperationResponse API provides methods to set and get data on the current CTIOperationResponse object.

You use CTIOperationResponse objects to pass information between an operation handler and a message transformer within the Cloud Call Center framework.

Typically, an operation handler is responsible for setting values on the CTIOperationResponse object as it processes the associated request. A message transformer is then responsible for getting the values from the CTIOperationRequest object and building the CTI-specific payload that is sent back to the computer telephony integrator (CTI) provider.

The ServiceNow base system provides working operation handlers and message transformers that enable connection to Amazon Connect. When building contact flows within Amazon Connect, there are two integration points between Amazon services and a ServiceNow instance:

- Amazon Web Services (AWS) Lambda Proxy (Invoke AWS Lambda function)
- AWS Lex Bot (Get Customer Input)

You can find the available operation handlers and message transformers for these integration points in the Operation Handlers [sn_cti_operation_handler] and Provider Message Transformer [sn_cti_provider_msg_transformer] tables.

The following operation handler script shows how to use various CTIOperationResponse methods to set values on the CTIOperationResponse object.

```javascript
(function(/*CTIOperationRequest*/ request, /*CTIOperationResponse*/ response) {
    try {
        var state = request.getParameter('$state');
        if(!state) {
            state = 'new';
        }
        var phone = request.getParameter('contact.phone');
        var username = request.getParameter('contact.username');
        var someDataPresent = phone || username;
        if(!someDataPresent) {
            throw 'phone or username must be supplied';
        }
    return operationRequest;
})(httpRequest, operationRequest, ctx);
```

if('new' === state) {
    var userGr = null;
    if(phone || username) {
        userGr = new GlideRecordSecure('sys_user');
        var qc = null;
        if(phone) {
            qc = userGr.addQuery('phone', phone);
            qc.addOrCondition('mobile_phone', phone);
            qc.addOrCondition("home_phone", phone);
        }
        if(username) {
            if(qc) {
                qc.addOrCondition('user_name', username);
            } else {
                qc = userGr.addQuery('user_name', username);
            }
        }
        // If there was criteria then run the query
        if(qc) {
            userGr.query();
        } else {
            userGr = null;
        }
    }
}

var foundUser = userGr && userGr.next();

var phonelogGr = new GlideRecord('sn_openframe_phone_log');
phonelogGr.initialize();
phonelogGr.setValue('call_id', request.getParameter('contact.id'));
phonelogGr.setValue('phone_number', phone);
if(foundUser) {
    phonelogGr.setValue('contact', userGr.getUniqueValue());
}
phonelogGr.insert();

var interactionGr = new GlideRecordSecure('interaction');
interactionGr.initialize();
interactionGr.setValue('type', 'phone');
interactionGr.setValue('short_description', 'User Contact via Phone: ' + phone);
interactionGr.setValue('channel_metadata_table', 'sn_openframe_phone_log');
interactionGr.setValue('channel_metadata_document', phonelogGr.getUniqueValue());
if(foundUser) {
interactionGr.setValue('opened_for', userGr.getUniqueValue());
response.setSessionAttribute('snc_user_first_name', userGr.getValue('first_name'));
response.setSessionAttribute('snc_user_last_name', userGr.getValue('last_name'));
response.setSessionAttribute('snc_user_sys_id', userGr.getUniqueValue());
}
else {
response.setSessionAttribute('snc_user_sys_id', "USER_NOT_FOUND");
}
interactionGr.setValue('state', 'new');

var interactionId = interactionGr.insert();

response.setStatusCode(200);
response.setMessage('success');
response.setSessionAttribute('interactionTable', 'interaction');
response.setSessionAttribute('interactionId', interactionId);

})

} catch(e) {
ctx.setError(e);
}

})(request, response);

For additional information on creating operation handlers, see Configure a contact flow for an automated caller interaction.

The following message transformer script gets the values set on the CTIOperationResponse object and stores them in the CTI-specific payload that is then sent back to the CTI provider.

(function /*CTIOperationResponse*/operationResponse, /*HTTPResponse*/ httpResponse) {
// AWS Connect Lambda expects name value pairs only
var out = {};
for(var k in operationResponse.getSessionAttributes()) {
    out[k] = operationResponse.getSessionAttributes()[k];
}
out.statusCode = operationResponse.getStatusCode();
out.message = operationResponse.getMessage();
httpResponse.setBody(out);
})(operationResponse, httpResponse);

This API runs in the sn_cti_core namespace. Before you are able to access the CTIOperationRequest API, the Cloud Call Center Core (sn_cti_core) application must be installed. For information on this installation, see Install Cloud Call Center applications.
For additional information on the Cloud Call Center, see Cloud Call Center.

CTIOperationResponse - CTIOperationResponse(String origin)

Instantiates a CTIOperationResponse object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```java
var response = new sn_cti_core.CTIOperationResponse();
response.setMinorVersion(3);
```

CTIOperationResponse - getAuthToken()

Returns the authentication token that was set on the CTIOperationResponse object.

This token is used by the Cloud Call Center framework to authenticate the current Cloud Call Center user before executing the requested operation handler if the handler's `auth_required` flag is set to true. The `auth_required` flag is a field in the Operation Handler `[sn_cti_operation_handler]` table. The life of an authentication token should be for the life of the call session, but is determined by the CTI provider.

You can define whatever authentication/authorization handling required by your implementation by creating your own authentication operation handler. Regardless of how the authentication token is generated, the message translator must pass the token back in the CTI payload. Additionally, the CTI provider must store this authentication token locally and pass it in each operation request that requires authentication.

If using the instance provided authenticate operation handler, the handler initiates the creation of the authentication token based on a four-digit user-entered pin. It then sets the authentication token in the sessionAttributes object of the CTIOperationResponse object. The associated message transformer translates the sessionAttributes object into the CTI-specific payload and then sends it to the CTI provider.

⚠️ Note: If the authentication token is not passed, all requests to execute operation handlers with the `auth_required` flag set will fail. If you do not use authentication, you do not need to maintain authentication tokens.

The ServiceNow base system provides working operation handlers and message transformers that enable connection to Amazon Connect. When building
contact flows within Amazon Connect, there are two integration points between Amazon services and a ServiceNow instance:

- Amazon Web Services (AWS) Lambda Proxy (Invoke AWS Lambda function)
- AWS Lex Bot (Get Customer Input)

You can find the available operation handlers and message transformers for these integration points in the Operation Handlers [sn.cti_operation_handler] and Provider Message Transformer [sn.cti_provider_msg_transformer] tables.

<table>

</tbody>
</table>

```javascript
var response = new sn.cti_core.CTIOperationResponse();
var token = response.getAuthToken();
```

**CTIOperationResponse - getError()**

Returns the error object associated with the current CTIOperationResponse object.

You might use this information to formulate the payload returned to the computer telephony integration (CTI) provider.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Operation error information. The format of this object is determined by the CTI provider. If an error does not exist, returns null.</td>
</tr>
</tbody>
</table>

```
(function( /*CTIProviderResponseExecutionContext*/ ctx, /*CTIOperationRequest*/ operationRequest, /*CTIOperationResponse*/ operationResponse, /*HTTPResponse*/ httpResponse) {

    var sessionAttributes = {},
        intentResponse;
    var statusCode = -1;
    var message = 'Unprocessed';
    if (operationResponse) {
        statusCode = operationResponse.getStatusCode();
        sessionAttributes = operationResponse.getSessionAttributes();
        message = operationResponse.getMessage();
        var error = operationResponse.getError();
        if (error) {
            sessionAttributes.error = error;
        }
    }

    if (sn_cti_core.CTIRequestDispatcher.Constants.HTTP.Status.AUTH_REQUIRED.code === statusCode) {
        // first call for a secure action without authentication token
        sessionAttributes.statusCode = 401;
        sessionAttributes.message = message;
        intentResponse = {
            sessionAttributes: sessionAttributes,
            dialogAction: {
                type: 'Close',
                fulfillmentState: 'Fulfilled',
                message: {
                    contentType: 'PlainText',
                    content: 'This operation requires authentication. Say authenticate for authentication.'
                }
            }
        };
    } else if ('DialogCodeHook' === operationRequest.getParameter('$$invocationSource')) {
        // pass back authToken and interactionId
        sessionAttributes.authToken = operationRequest.getAuthToken();
    }
}
```
sessionAttributes.interactionId = operationRequest.getInteractionSysId();
var originalSlots = operationRequest.getParameter('$$slots');
var responseParameters = operationResponse ? operationResponse.getParameters() : {};
responseParameters = responseParameters ? responseParameters : {};

// See if we processing happened and we got a dialogAction
var responseDialogAction = responseParameters['dialogAction'];

// Default dialog action
var dialogAction = {
    type: 'Delegate',
    slots: originalSlots
};

// If the response doesn't contain an override replay the inputs
if (responseDialogAction) {
    // We bypassed dialoghook so delegate and pass through inputs
dialogAction = responseDialogAction;
}
intentResponse = {
    sessionAttributes: sessionAttributes,
    dialogAction: dialogAction
};
} else {
    // Override required session attributes
    sessionAttributes.statusCode = statusCode;
    sessionAttributes.message = message;

    // Build response template
    intentResponse = {
        sessionAttributes: sessionAttributes,
        dialogAction: {
            type: 'Close',
            fulfillmentState: 'Fulfilled',
            message: {
                contentType: 'PlainText',
                content: message
            }
        }
    }
}
httpResponse.setBody(intentResponse);})}(ctx, operationRequest, operationResponse, httpResponse);
CTIOperationResponse - getInteractionSysId()

Returns the sys_id of the interaction record associated with the call session that was set on the CTIOperationResponse object.

The CTIOperationResponse - setInteractionSysId(String Id) method must have been called prior to calling this method.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The sys_id of the interaction record set on the CTIOperationResponse object. Interaction records are located in the Interaction [interaction] table. If the interaction record sys_id is not set, the method returns null.</td>
</tr>
</tbody>
</table>

var request = new sn_cti_core.CTIOperationResponse();
var interactionId = request.getInteractionSysId();

CTIOperationResponse - getMajorVersion()

Returns the major version of the computer telephony integrator (CTI) software set on the current CTIOperationResponse object.

Use this method if the CTI providers connected to your ServiceNow instance are running multiple versions of their software, as different software versions may require different payloads. If the payload is only slightly different between the software versions, it may make sense to have only a single message transformer. You can then handle the payload differences by just checking the version of software making the request within your message transformer. If the required payload is significantly different between versions, it may be more effective to use multiple message transformers.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Major version number of the CTI software.</td>
</tr>
<tr>
<td></td>
<td>If the major version was never set, returns 1.</td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_cti_core.CTIOperationResponse();
var majorVersion = response.getMajorVersion();
```

### CTIOperationResponse - getMessage()

Returns the message string set on the current CTIOperationResponse object.

Typically this is a message that is spoken back to the user once an operation is complete. You can set this value using the `CTIOperationResponse - setMessage(String message)` method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Message text. If no message exists, returns null.</td>
</tr>
</tbody>
</table>

```javascript
(function /*CTIOperationResponse*/operationResponse, /*HTTPResponse*/ httpResponse) {
  // AWS Connect Lambda expects name value pairs only
  var out = {};
  for(var k in operationResponse.getSessionAttributes()) {
    out[k] = operationResponse.getSessionAttributes()[k];
  }
  out.statusCode = operationResponse.getStatusCode();
  out.message = operationResponse.getMessage();
  httpResponse.setBody(out);
})(operationResponse, httpResponse);
```
CTIOperationResponse - getMinorVersion()

Returns the minor version of the computer telephony integrator (CTI) software set on the current CTIOperationResponse object.

Use this method if the CTI providers connected to your ServiceNow instance are running multiple versions of their software, as different software versions may require different payloads. If the payload is only slightly different between the software versions, it may make sense to have only a single message transformer. You can then handle the payload differences by just checking the version of software making the request within your message transformer. If the required payload is significantly different between versions, it may be more effective to use multiple message transformers.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Minor version number of the payload associated with this interaction. If the minor version was never set, returns 0.</td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_cti_core.CTIOperationResponse();
var minorVersion = request.getMinorVersion();
```

CTIOperationResponse - getParameter(String key)

Returns the value of a specified key previously set on the current CTIOperationResponse object.

Using the get/set parameter methods enables the passing of virtually any string or number value between an operation handler and a message transformer. The parameter object can contain zero or more key/value pairs of data that directly correlate to the current operation response. The operation handler determines what key/value pairs are required as it produces these values. Use the CTIOperationResponse - setParameter(String key, Object value) method to set parameters on the current CTIOperationResponse object.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>The name of the key value to return.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The value of the passed in key. If no such key exists, returns null.</td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_cti_core.CTIOperationResponse();
var parm = request.getParameter('contact.phone');
```

**CTIOperationResponse - getParameters()**

Returns the key-value pairs for all parameters that were previously set on the current CTIOperationResponse object.

Using the get/set parameter methods enables the passing of virtually any string or number value between an operation handler and a message transformer. The parameter object can contain zero or more key/value pairs of data that directly correlate to the current operation response. The operation handler determines what key/value pairs are required as it produces these values. Use the `CTIOperationResponse - setParameter(String key, Object value)` method to set parameters on the current CTIOperationResponse object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>A map of key-value pairs that were previously set on the CTIOperationResponse object. This key-value pairs are free-form and defined by the needs of the operation handler. The returned values are either Strings or Numbers.</td>
</tr>
</tbody>
</table>
function( /*CTIProviderResponseExecutionContext*/ ctx, /*CTIOperationRequest*/ operationRequest, /*CTIOperationResponse*/ operationResponse, /*HTTPResponse*/ httpResponse) {
  var sessionAttributes = {},
      intentResponse;
  var statusCode = -1;
  var message = 'Unprocessed';
  if (operationResponse) {
    statusCode = operationResponse.getStatusCode();
    sessionAttributes = operationResponse.getSessionAttributes();
    message = operationResponse.getMessage();
    var error = operationResponse.getError();
    if (error) {
      sessionAttributes.error = error;
    }
  }
  if (sn_cti_core.CTIRequestDispatcher.Constants.HTTP.Status.AUTH_REQUIRED.code === statusCode) {
    //first call for a secure action without authentication token
    sessionAttributes.statusCode = 401;
    sessionAttributes.message = message;
    intentResponse = {
      sessionAttributes: sessionAttributes,
      dialogAction: {
        type: 'Close',
        fulfillmentState: 'Fulfilled',
        message: {
          contentType: 'PlainText',
          content: 'This operation requires authentication. Say authenticate for authentication.'
        }
      }
    };
  } else if ('DialogCodeHook' === operationRequest.getParameter('$$invocationSource')) {
    //pass back authToken and interactionId
    sessionAttributes.authToken = operationRequest.getAuthToken();
    sessionAttributes.interactionId = operationRequest.getInteractionSysId();
    var originalSlots = operationRequest.getParameter('$$slots');
    var responseParameters = operationResponse ? operationResponse.getParameters() : {};
    responseParameters = responseParameters ? responseParameters : {};
    // See if processing happened and we got a dialogAction
    var responseDialogAction = responseParameters['dialogAction'];
    // Default dialog action
var dialogAction = {
    type: 'Delegate',
    slots: originalSlots
};
// If the response doesn't contain an override replay the inputs
if (responseDialogAction) {
    // We bypassed dialoghook so delegate and pass through inputs
dialogAction = responseDialogAction;
}
intentResponse = {
    sessionAttributes: sessionAttributes,
    dialogAction: dialogAction
};
} else {
// Override required session attributes
    sessionAttributes.statusCode = statusCode;
    sessionAttributes.message = message;
// Build response template
intentResponse = {
    sessionAttributes: sessionAttributes,
    dialogAction: {
        type: 'Close',
        fulfillmentState: 'Fulfilled',
        message: {
            contentType: 'PlainText',
            content: message
        }
    }
};
}
httpResponse.setBody(intentResponse);
})(ctx, operationRequest, operationResponse, httpResponse);

**CTIOperationResponse - getSessionAttribute(String key)**

Returns the value for a specified session attribute key set on the current CTIOperationResponse object.

Using the get/set session attribute methods enables the passing of virtually any string or number value between an operation handler and a message transformer. Session attributes can also be accessed within a contact flow. The sessionAttribute object can contain zero or more key/value pairs of data, such as the contact's phone number, that are valid for the duration of a computer telephony integration provider defined session. The operation handler
determines what session attribute key/value pairs are needed as it utilizes these values during processing. Typically the operation handler sets these attributes on the CTIOperationResponse object by calling the `CTIOperationResponse - setSessionAttribute(String key, Object value)` method and the message transformer consumes the attributes using this method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>The name of the key value to return.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value of the passed in key. If no such key exists, returns null.</td>
</tr>
</tbody>
</table>

```javascript
var response = new sn_cti_core.CTIOperationResponse();
var phoneAttribute = response.getSessionAttribute('contact.phone');
```

### CTIOperationResponse - getSessionAttributes()

Returns the key-value pairs for all session attributes that were previously set on the current CTIOperationResponse object.

Using the get/set session attribute methods enables the passing of virtually any string or number value between an operation handler and a message transformer. Session attributes can also be accessed within a contact flow. The sessionAttribute object can contain zero or more key/value pairs of data, such as the contact's phone number, that are valid for the duration of a computer telephony integration provider defined session. The operation handler determines what session attribute key/value pairs are needed as it utilizes these values during processing. Typically the operation handler sets these attributes on the CTIOperationResponse object by calling the `CTIOperationResponse - setSessionAttribute(String key, Object value)` method and the message transformer consumes the attributes using this method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>A map of key-value pairs that were previously set on the CTIOperationResponse object. This key-value pairs are free-form and defined by the needs of the operation handler. The returned values are either Strings or Numbers.</td>
</tr>
</tbody>
</table>

```javascript
(function(/*CTIOperationResponse*/operationResponse, /*HTTPResponse*/ httpResponse) {
    // AWS Connect Lambda expects name value pairs only
    var out = {};
    for(var k in operationResponse.getSessionAttributes()) {
        out[k] = operationResponse.getSessionAttributes()[k];
    }
    out.statusCode = operationResponse.getStatusCode();
    out.message = operationResponse.getMessage();
    httpResponse.setBody(out);
})(operationResponse, httpResponse);
```

**CTIOperationResponse - getStatusCode()**

Returns the status code set on the current CTIOperationResponse object.

These status codes should correspond with standard HTTP status codes, such as 200 for success, 401 for authorization required. Typically, the resultant status codes are determined by the operation handler and are set on the CTIOperationResponse object using the `CTIOperationResponse - setStatusCode(Number statusCode)` method. The message transformer then uses this method to include the status code in the payload returned to the computer telephony integrator provider.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>(207,667,217,681)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Status code of the current operation. If a status code has not been set, returns -1.</td>
</tr>
</tbody>
</table>
(function /*CTIOperationResponse*/operationResponse, /*HTTPResponse*/ httpResponse) {
    // AWS Connect Lambda expects name value pairs only
    var out = {};
    for(var k in operationResponse.getSessionAttributes()) {
        out[k] = operationResponse.getSessionAttributes()[k];
    }
    out.statusCode = operationResponse.getStatusCode();
    out.message = operationResponse.getMessage();
    httpResponse.setBody(out);
})(operationResponse, httpResponse);

CTIOperationResponse - setAuthToken(String token)
Sets an authentication token on the current CTIOperationResponse object.

This token is used by the Cloud Call Center framework to authenticate the current Cloud Call Center user before executing the requested operation handler if the handler's auth_required flag is set to true. The auth_required flag is a field in the Operation Handler [sn_cti_operation_handler] table. The life of an authentication token should be for the life of the call session, but is determined by the CTI provider.

You can define whatever authentication/authorization handling required by your implementation by creating your own authentication operation handler. Regardless of how the authentication token is generated, the message translator must pass the token back in the CTI payload. Additionally, the CTI provider must store this authentication token locally and pass it in each operation request that requires authentication.

If using the instance provided authenticate operation handler, the handler initiates the creation of the authentication token based on a four-digit user-entered pin. It then sets the authentication token in the sessionAttributes object of the CTIOperationResponse object. The associated message transformer translates the sessionAttributes object into the CTI-specific payload and then sends it to the CTI provider.

⚠️ Note: If the authentication token is not passed, all requests to execute operation handlers with the auth_required flag set will fail. If you do not use authentication, you do not need to maintain authentication tokens.

The ServiceNow base system provides working operation handlers and message transformers that enable connection to Amazon Connect. When building contact flows within Amazon Connect, there are two integration points between Amazon services and a ServiceNow instance:
- Amazon Web Services (AWS) Lambda Proxy (Invoke AWS Lambda function)
- AWS Lex Bot (Get Customer Input)

You can find the available operation handlers and message transformers for these integration points in the Operation Handlers [sn_cti_operation_handler] and Provider Message Transformer [sn_cti_provider_msg_transormer] tables.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The authentication token to use to authenticate operations that have the <code>auth_required</code> flag set.</td>
</tr>
</tbody>
</table>

```javascript
var response = new sn_cti_core.CTIOperationResponse();
var authenticate = '<Your authentication code here>'; // Authenticate the user
if (authenticated) {
  var claims = {
    "interactionId":interactionGr.sys_id.toString()
  };
  var jwt = new sn_cti_core.AuthHelpers().generateJWT(claims);
  response.setAuthToken(jwt);
}
```

#### CTIOperationResponse - setError(Object error)

Sets the error object in the current CTIOperationResponse object.

You can use the error object in the component to formulate the payload to send to the computer telephony integrator (CTI) provider.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Object</td>
<td>Information about the error that was detected while processing the requested operation. The format of this object is determined by the CTI provider.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var response = new sn_cti_core.CTIOperationResponse();
response.setError(new Error("You did not supply a field"));
```

`CTIOperationResponse - setInteractionSysId(String Id)`

Sets the sys_id of the interaction record associated with the operation request on the current CTIOperationResponse object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>String</td>
<td>The sys_id to set for the current interaction.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var response = new sn_cti_core.CTIOperationResponse();
response.setInteractionSysId('98529cc55380001048e5ddeff7b120b');
```

`CTIOperationResponse - setMajorVersion(Number majorVersion)`

Sets the major version of the computer telephony integrator (CTI) provider software making the request on the associated CTIOperationResponse object.

Use this method if the CTI providers connected to your ServiceNow instance are running multiple versions of their software, as different software versions may require different payloads. If the payload is only slightly different between the software versions, it may make sense to have only a single message transformer. You can then handle the payload differences by just checking the version of software making the request within your message transformer. If the required payload is significantly different between versions, it may be more effective to use multiple message transformers.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>majorVersion</td>
<td>Number</td>
<td>Major version of the CTI provider software making the operation request.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If this value was not previously set, returns 1.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var request = new sn_cti_core.CTIOperationResponse();
request.setMajorVersion(2);
```

`CTIOperationResponse - setMessage(String message)`

Sets a text message on the current `CTIOperationResponse` object.

Typically this is a message that is spoken back to the user once an operation is complete and is set by the associated operation handler. The message transformer then uses the `CTIOperationResponse - getMessage()` method to obtain the message and pass it back to the computer telephony integration provider.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Message text</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
(function(/*CTIOperationRequest*/ request, /*CTIOperationResponse*/ response, /*Context*/ ctx) {
    var notes = '', lang = request.getLanguage();
    try {
```
var interactionGr = request.getInteractionRecord();

var now_GR = new GlideRecord('sys_user');
if(interactionGr && now_GR.get(interactionGr.opened_for.toString())) {
    if(now_GR.locked_out == true) {
        notes += gs.getMessageLang("User record found locked. Unlocking the account.\n", lang);
        now_GR.locked_out=false;
        now_GR.update();
        response.setStatusCode(200);
        response.setMessage(gs.getMessageLang("Your account has been unlocked.", lang));
    } else {
        notes += gs.getMessageLang("User record not locked.\n", lang);
        response.setStatusCode(200);
        response.setMessage(gs.getMessageLang("Your account doesn't seem to be locked.\", lang));
    }
} else {
    notes += gs.getMessageLang("User record not found. Transfer to agent\n", lang);
    response.setStatusCode(302);
    response.setMessage(gs.getMessageLang("I am unable to find your record. Let me transfer to someone who can help.\", lang));
}
if(interactionGr) {
    interactionGr.work_notes = notes;
    interactionGr.update();
}
} catch(e) {
    ctx.setError(e);
}
})(request, response, ctx);

CTIOperationResponse - setMinorVersion(Number minorVersion)

Sets the minor version of the computer telephony integrator (CTI) provider software making the request on the associated CTIOperationResponse object.

Use this method if the CTI providers connected to your ServiceNow instance are running multiple versions of their software, as different software versions may require different payloads. If the payload is only slightly different between the software versions, it may make sense to have only a single message transformer. You can then handle the payload differences by just checking the version of software making the request within your message transformer. If the required
payload is significantly different between versions, it may be more effective to use multiple message transformers.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>minorVersion</td>
<td>Number</td>
<td>Minor version of the CTI provider software making the operation request.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If this value was not previously set, returns 0.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var response = new sn_cti_core.CTIOperationResponse();
response.setMinorVersion(3);
```

**CTIOperationResponse - setParameter(String key, Object value)**

Sets the specified key-value pair on the associated CTIOperationResponse object.

Using the get/set parameter methods enables the passing of virtually any string or number value between an operation handler and a message transformer. The parameter object can contain zero or more key/value pairs of data that directly correlate to the current operation request. The operation handler determines what key/value pairs are required as it consumes these values. Typically the operation handler sets these parameters on the CTIOperationResponse object by calling this method and the message transformer consumes them using the `CTIOperationResponse - getParameter(String key)` or `CTIOperationResponse - getParameters()` method.

ℹ Note: You should only store objects that can survive a `JSON.parse(JSON.stringify(object))` operation. Objects not meeting this criteria may not propagate correctly through the entire operation processing chain.

For example:

```javascript
var x = {
    "string": 'abc',
    "int": 123,
};
```
```javascript
"float": 1.234,
"number": new Number(3),
"boolean": true,
"date": new Date(2006, 0, 2, 15, 4, 5),
"object": {    "string": 'abc',
    "int": 123,
    "float": 1.234,
    "number": new Number(3),
    "boolean": true,
    "date": new Date(2006, 0, 2, 15, 4, 5)
},
"function": function(abc) {

}
}

var stringify = JSON.stringify(x);
gs.info(stringify);
var hydrate = JSON.parse(stringify);
var stringify2 = JSON.stringify(hydrate);
gs.info(stringify2);

Produces:

```json
{
"string": "abc",
"int": 123,
"float": 1.234,
"number": 3,
"boolean": true,
"date": "2006-01-02T23:04:05.000Z",
"object": {
"string": "abc",
"int": 123,
"float": 1.234,
"number": 3,
"boolean": true,
"date": "2006-01-02T23:04:05.000Z"
}
}
```

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Name of the key under which to store the associated value.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>Value to store for the key. Valid data types:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• string</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• int</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• float</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• number</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>boolean</td>
<td></td>
</tr>
<tr>
<td></td>
<td>date</td>
<td></td>
</tr>
<tr>
<td></td>
<td>object</td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var response = new sn_cti_core.CTIOperationResponse();
response.setParameter('contact.phone', '+15552222345');
response.setParameter('contact.okToCall', true);
response.setParameter('contact.address', {
    street: '1234 Main St'
    city: 'API City',
    zip: 91335
});
```

**CTIOperationResponse - setSessionAttribute(String key, Object value)**

Sets the specified session attribute key-value pair on the associated CTIOperationResponse object.

Using the get/set session attribute methods enables the passing of virtually any string or number value between an operation handler and a message transformer. The sessionAttribute object can contain zero or more key/value pairs of data that are valid for the duration of a computer telephony integration provider defined session. Session attributes can also be accessed within a contact flow. The operation handler determines what session attribute key/value pairs are needed as it consumes these values. Typically the operation handler sets these attributes on the CTIOperationResponse object by calling this method and the message transformer gets the attributes using the `CTIOperationResponse - getSessionAttribute(String key)` or `CTIOperationResponse - getSessionAttributes()` method.
Note: You should only store objects that can survive a JSON.parse(JSON.stringify(object)) operation. Objects not meeting this criteria may not propagate correctly through the entire operation processing chain.

For example:

```javascript
var x = {
    "string": 'abc',
    "int": 123,
    "float": 1.234,
    "number": new Number(3),
    "boolean": true,
    "date": new Date(2006, 0, 2, 15, 4, 5),
    "object": {
        "string": 'abc',
        "int": 123,
        "float": 1.234,
        "number": new Number(3),
        "boolean": true,
        "date": new Date(2006, 0, 2, 15, 4, 5)
    },
    "function": function(abc) {
    }
};

var stringify = JSON.stringify(x);
gs.info(stringify);
var hydrate = JSON.parse(stringify);
var stringify2 = JSON.stringify(hydrate);
gs.info(stringify2);
```

Produces:

```javascript
```
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Name of the session attribute key under which to set the associated value.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>Value to set. Valid data types:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• string</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• int</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• float</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• number</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• boolean</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• date</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• object</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var response = new sn_cti_core.CTIOperationResponse();
response.setSessionAttribute('contact.phone', '+15552222345');
response.setSessionAttribute('contact.okToCall', true);
response.setSessionAttribute('contact.address', {
  street: '1234 Main St'
  city: 'API City',
  zip: 91335
});
```

**CTIOperationResponse - setStatusCode(Number statusCode)**

Sets the status code of the current operation request on the CTIOperationResponse object.

You can use any integer values to define the status, but it is recommended that you emulate the HTTP status codes, such as 200 = Ok/Success, 400 = Bad Request, 401 = Unauthorized.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>statusCode</td>
<td>Number</td>
<td>Integer that uniquely identifies the status of the requested operation.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
(function(/*CTIOperationRequest*/ request, /*CTIOperationResponse*/ response, /*Context*/ ctx) {
    var notes = '', lang = request.getLanguage();
    try {
        var interactionGr = request.getInteractionRecord();
        var now_GR = new GlideRecord('sys_user');
        if(interactionGr && now_GR.get(interactionGr.opened_for.toString())) {
            if(now_GR.locked_out == true) {
                notes += gs.getMessageLang("User record found locked. Unlocking the account.
                ", lang);
                now_GR.locked_out=false;
                now_GR.update();
                response.setStatusCode(200);
                response.setMessage(gs.getMessageLang("Your account has been unlocked.", lang));
            } else {
                notes += gs.getMessageLang("User record not locked.
                ", lang);
                response.setStatusCode(200);
                response.setMessage(gs.getMessageLang("Your account doesn't seem to be locked.",
                
                lang));
            }
        } else {
            notes += gs.getMessageLang("User record not found. Transfer to agent
            ", lang);
            response.setStatusCode(302);
            response.setMessage(gs.getMessageLang("I am unable to find your record. Let me
            
            transfer to someone who can help.", lang));
        }
        if(interactionGr) {
            interactionGr.work_notes = notes;
        }
    }
});
```
CustomEvent - Client

You can use CustomEvent API to show qualified embedded help in the right sidebar.

See Use embedded help qualifiers for more information.

CustomEvent - fireAll(String event, String qualifier)

Show the embedded-help content specified by the qualifier parameter in the right sidebar.

Before using the fireAll() method, you must have created the Embedded Help qualifier and help content.

⚠️ Note: To write to the debug log, make a call to the global function jslog().

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>event</td>
<td>String</td>
<td>The event to send. Must be the string &quot;embedded_help:load_embedded_help&quot;</td>
</tr>
<tr>
<td>qualifier</td>
<td>String</td>
<td>The qualifier name created in the Embedded Help application.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

var qualifier = 'your-EH-qualifier';

CustomEvent.fireAll("embedded_help:load_embedded_help", qualifier);
Data - Scoped, Global
A Data object contains the results of transform performed by a
\texttt{sn\_clotho.Client.transform()} method.

Do not use a constructor to create an instance of this class, instead use the
object returned by the \texttt{sn\_clotho.Client.transform()} method.

The \texttt{Data} class can be used in scoped and global server scripts. When using the
\texttt{Data} class, use the \texttt{sn\_clotho} namespace identifier.

This class is part of the MetricBase application.

**Scoped Data - \texttt{getEnd()}**
Returns the end time for data in the Data object.

<table>

<tr>
<td>GlideDateTime</td>
</tr>
</tbody>
</table>

**Scoped Data - \texttt{getLabel()}**
Returns the label assigned by the \texttt{sn\_clotho.ClothoTransform.label()} method.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>
Scoped Data - `getMetricName()`

Returns the name of the metric of the data series. Returns null when the data object is associated with multiple data series.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of the metric field. Returns null when the data object is associated with multiple data series.</td>
</tr>
</tbody>
</table>

Scoped Data - `getPeriod()`

Returns the time period in milliseconds.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The elapsed time in seconds.</td>
</tr>
</tbody>
</table>

Scoped Data - `getStart()`

Returns the start time for data in the Data object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDateTime</td>
<td>The time for the first data point.</td>
</tr>
</tbody>
</table>

Scoped Data - getSubject()

Returns the subject of the data series. Returns null when the data object is associated with multiple data series.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The subject field value of the subject GlideRecord. This is generally the sys_id of the subject GlideRecord.</td>
</tr>
</tbody>
</table>

Scoped Data - getTableName()

Returns the name of the table assigned in the DataSelector class constructor. Returns null when the data object is associated with multiple data series.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Table name. Returns null when the data object is associated with multiple data series.</td>
</tr>
</tbody>
</table>
Scoped Data - getValues()
Returns an array of values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of numbers.</td>
</tr>
</tbody>
</table>

Scoped Data - size()
Returns the number of values in the Data object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of values in the object.</td>
</tr>
</tbody>
</table>

DataBuilder - Scoped, Global
Use the DataBuilder class to create a series of data points for a metric. Use the sn_clotho.Client.put() method to save the values.

The DataBuilder class can be used in scoped and global server scripts. When using the DataBuilder class, use the sn_clotho namespace identifier.

This class is part of the MetricBase application.

Scoped DataBuilder - add(GlideDateTime start, Array value)
Add a series of data points to the DataBuilder object. Each data point is a time stamp and a value.
Uses the start parameter and the retention policy collection period to calculate the time stamp for each value in the array. The first value has the start parameter as the time stamp. This method does not save the data in the MetricBase database. Use the `sn_clotho.Client.put()` method to save the values.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>GlideDateTime</td>
<td>The time stamp for the first data point. Subsequent time stamps are calculated using the retention policy collection period.</td>
</tr>
<tr>
<td>value</td>
<td>Array</td>
<td>An array of numbers.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataBuilder</td>
<td>The same DataBuilder object.</td>
</tr>
</tbody>
</table>

```javascript
var points = [7, 0.5, 273];
var dataBuilder = new sn_clotho.DataBuilder(now_GR, 'cpu_percentage');
// this creates a GlideDateTime object set to the current date and time
var time = new GlideDateTime();
dataBuilder.add(time, points);
```

### Scoped DataBuilder - add(GlideDateTime start, Number value)

Add a data point to the DataBuilder object. Each data point is a time stamp and a value. This method does not save the data point in the metric. Use the `sn_clotho.Client.put()` method to save the values.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>GlideDateTime</td>
<td>The time stamp for the data point.</td>
</tr>
<tr>
<td>value</td>
<td>Number</td>
<td>The value of the data point.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataBuilder</td>
<td>The DataBuilder object.</td>
</tr>
</tbody>
</table>

```javascript
var dataBuilder = new sn_clotho.DataBuilder(now_GR, 'cpu_percentage');
// this creates a GlideDateTime object set to the current date and time
var time = new GlideDateTime();
dataBuilder.add(time, 0.6);
```

**Scoped DataBuilder - DataBuilder(Object glideRecord, String subject, String metric)**

Creates an instance of the DataBuilder class.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glideRecord</td>
<td>Object</td>
<td>GlideRecord from which to obtain the domain.</td>
</tr>
<tr>
<td>subject</td>
<td>String</td>
<td>The sys_id of the GlideRecord associated with this series.</td>
</tr>
<tr>
<td>metric</td>
<td>String</td>
<td>The field name of the metric.</td>
</tr>
</tbody>
</table>

```javascript
// Where cpu_percentage is the name of the metric
var dataBuilder = new sn_clotho.DataBuilder(now_GR, 'cpu_percentage');
```

**DCManager - Global**

The DCManager API enables you to group data by type.

With the DCManager API, you can:

- Assign data classifications to existing dictionary entries.
- Look up the data classifications for specific dictionary entries.
- Remove all data classifications associated with specific dictionary entries.
- Retrieve a list of all data classifications available in the current domain.

This API requires the Data Classification [com.glide.data_classification] plugin.

For more information, see Data Classification.
DCManager - classify(String dictEntries, String dataClasses)

Assigns pre-defined or user-defined data classifications to existing dictionary entries.

Requires the admin or data_classification_admin role.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>dictEntries</td>
</tr>
<tr>
<td>dataClasses</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

This example finds records containing social security numbers and classifies the records as confidential.

```javascript
var dcm = new SNC.DCManager();
var confidentialClass = {};
var ssnFields = [];
var dataClasses = JSON.parse(dcm.getAllDataClasses());

// Get the Confidential data class record
dataClasses.forEach(function (dataClass) {
    if (dataClass.name == "Confidential")
        confidentialClass = dataClass;
});

// Find fields that seem to be strong social security numbers
var dictionaryGR = new GlideRecord("sys_dictionary");
dictionaryGR.addQuery("element", "ssn").addOrCondition("element", "social_security_number");
dictionaryGR.query();
```
while (dictionaryGR.next())
    ssnFields.push(dictionaryGR.getUniqueValue());

// Classify any found entries as Confidential
if (ssnFields.length > 0)
    dcm.classify(ssnFields.join(), confidentialClass.sys_id);

Output:
"Successfully stored the data classification configurations"

DCManager - clearClassification(String dictEntries)
Removes all data classifications for the specified dictionary entries.
Requires the admin or data_classification_admin role.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dictEntries</td>
<td>String</td>
<td>The sys_ids of the records you want to remove classifications from. The sys_ids are from the Dictionary [sys_dictionary] table. Entered as a comma-separated list enclosed in a string.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Message describing the result of the operation.</td>
</tr>
</tbody>
</table>

This example removes the data classification for a dictionary entry.

```javascript
var dcm = new SNC.DCManager();
gs.info(dcm.clearClassification("445de0a6dba30300efc57416bf9619b0"));
```

Output:
"Classifications removed for the specified dictionary entries"

DCManager - getAllDataClasses()
Returns a list of all data classifications available in the current domain.
Requires the admin, data_classification_admin, or data_classification_auditor role.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Array&gt;</td>
<td>Result of the request. Returns the sys.id and name for each available data classification. If there are no data classifications, it returns an empty array.</td>
</tr>
<tr>
<td></td>
<td>Data classifications can be organized into parent-child relationships. If there are parent data classifications, they are identified in the result.</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>[</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;parent&quot;: (Object),</td>
</tr>
<tr>
<td></td>
<td>&quot;sys_id&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;name&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td>&lt;Array&gt;.parent</td>
<td>Entry for a parent data classification.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>
<td>```</td>
</tr>
<tr>
<td></td>
<td>&quot;parent&quot;: (</td>
</tr>
<tr>
<td></td>
<td>&quot;sys_id&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;name&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>)</td>
</tr>
<tr>
<td>&lt;Array&gt;.parent.sys_id</td>
<td>Sys_id of the parent data classification from the Data Classification [data_classification] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Array&gt;.parent.name</td>
<td>Name of the parent data classification.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Array&gt;.sys_id</td>
<td>Sys_id of the data classification from the Data Classification [data_classification] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;Array&gt;.name</code></td>
<td>Name of the data classification.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

This example retrieves a list of all available data classifications.

```javascript
var dcm = new SNC.DCManager();
gs.info(dcm.getAllDataClasses());
```

Output:

```
[
  {
    "parent": {
      "sys_id": "a9670fc773fc1010ae8dd21eef6a735",
      "name": "Confidential"
    },
    "sys_id": "348107b951d71010f877f3f178e7dd0d",
    "name": "Personally identifiable information"
  },
  {
    "sys_id": "a9670fc773fc1010ae8dd21eef6a735",
    "name": "Confidential"
  },
  {
    "sys_id": "59b7070b73fc1010ae8dd21eef6a764",
    "name": "Restricted"
  },

    "name": "Internal"
  },
  {
    "sys_id": "f5b4cf4773fc1010ae8dd21eef6a766",
    "name": "Public"
  }
]
```

**DCManager - getClassification(String dictEntries)**

Retrieves all data classifications for the specified dictionary entries.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dictEntries</td>
<td>String</td>
<td>The sys_ids of the records you want to retrieve classifications for. The sys_ids are from the Dictionary [sys_dictionary] table. Entered as a comma-separated list enclosed in a string.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;</td>
<td>JSON object containing each dictionary entry's sys_id with an array of its associated data classes. If there are no associated data classifications, it returns a message describing the result of the operation. Data classifications can be organized into parent-child relationships. If there are parent data classifications, they are identified in the result.</td>
</tr>
</tbody>
</table>

Data type: Object

```
{
  <sys_dictionary_sys_id>: [
    {
      "parent": {Object},
      "sys_id": "String",
      "name": "String"
    }
  ]
}
```

<Object>.parent Entry for a parent data classification. Data type: Object

```
"parent": {
  "sys_id": "String",
  "name": "String"
}
```

<Object>.parent.sys_id_sys_id of the parent data classification from the Data Classification [data_classification] table. Data type: String
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.parent.name</td>
<td>Name of the parent data classification.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.sys_id</td>
<td>Sys_id of the data classification from the Data Classification [data_classification] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.name</td>
<td>Name of the data classification.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

This example retrieves the data classifications for a dictionary entry.

```javascript
var dcm = new SNC.DCManager();
gs.info(dcm.getClassification("445de0a6dba30300efc57416bf9619b0"));
```

**Output:**

```javascript
{
  "445de0a6dba30300efc57416bf9619b0": [
    {
      "parent": {
        "sys_id": "a9670fc773fc1010ae8dd21efaf6a735",
        "name": "Confidential"
      },
      "sys_id": "348107b951d71010f877f3f178e7dd0d",
      "name": "Personally identifiable information"
    }
  ]
}
```

**ScopedDCManager - Scoped**

The `ScopedDCManager` API enables you to group data by type.

With the `ScopedDCManager` API, you can:

- Assign data classifications to existing dictionary entries.
- Look up the data classifications for specific dictionary entries.
- Remove all data classifications associated with specific dictionary entries.
- Retrieve a list of all data classifications available in the current domain.
This API requires the Data Classification [com.glide.data_classification] plugin. For more information, see Data Classification.

ScopedDCManager - classify(String dictEntries, String dataClasses)
Assigns pre-defined or user-defined data classifications to existing dictionary entries.

Requires the admin or data_classification_admin role.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dictEntries</td>
<td>String</td>
<td>The sys_ids of the records you want to classify. The sys_ids are from the Dictionary [sys_dictionary] table. Entered as a comma-separated list enclosed in a string.</td>
</tr>
<tr>
<td>dataClasses</td>
<td>String</td>
<td>The sys_ids of the data classifications you want to assign. The sys_ids are from the Data Classification [data_classification] table. Entered as a comma-separated list enclosed in a string.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Message describing the result of the operation.</td>
</tr>
</tbody>
</table>

This example finds records containing social security numbers and classifies the records as confidential.

```javascript
var dcm = new global.ScopedDCManager();
var confidentialClass = {};
var ssnFields = [];
var dataClasses = JSON.parse(dcm.getAllDataClasses());

// Get the Confidential data class record
dataClasses.forEach(function (dataClass) {
  if (dataClass.name == "Confidential")
    confidentialClass = dataClass;
});

// Find the fields that seem to be strong social security numbers
var dictionaryGR = new GlideRecord("sys_dictionary");
```
dictionaryGR.addQuery("element", "ssn").addOrCondition("element", "social_security_number");
dictionaryGR.query();
while (dictionaryGR.next())
    ssnFields.push(dictionaryGR.getUniqueValue());

// Classify any found entries as confidential
if (ssnFields.length > 0)
    dcm.classify(ssnFields.join(), confidentialClass.sys_id);

Output:
"Successfully stored the data classification configurations"

ScopedDCManager - clearClassification(String dictEntries)
Removes all data classifications for the specified dictionary entries.
Requires the admin or data_classification_admin role.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dictEntries</td>
<td>String</td>
<td>The sys_ids of the records you want to remove classifications from. The sys_ids are from the Dictionary [sys_dictionary] table. Entered as a comma-separated list enclosed in a string.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Message describing the result of the operation.</td>
</tr>
</tbody>
</table>

This example removes the data classification for a dictionary entry.

```javascript
var dcm = new global.ScopedDCManager();
gs.info(dcm.clearClassification("445de0a6dba30300efc57416bf9619b0"));
```

Output:
"Classifications removed for the specified dictionary entries"

ScopedDCManager - getAllDataClasses()

Returns a list of all data classifications available in the current domain.
Requires the admin, data_classification_admin, or data_classification_auditor role.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Array&gt;</td>
<td>Result of the request. Returns the sys_id and name for each available data classification. If there are no data classifications, it returns an empty array. Data classifications can be organized into parent-child relationships. If there are parent data classifications, they are identified in the result. Data type: Array</td>
</tr>
<tr>
<td>&lt;Array&gt;.parent</td>
<td>Entry for a parent data classification.</td>
</tr>
<tr>
<td>&lt;Array&gt;.parent.sys_id</td>
<td>Sys_id of the parent data classification from the Data Classification [data_classification] table.</td>
</tr>
<tr>
<td>&lt;Array&gt;.parent.name</td>
<td>Name of the parent data classification.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Array&gt;.sys_id</td>
<td>Sys_id of the data classification from the Data Classification [data_classification] table. Data type: String</td>
</tr>
<tr>
<td>&lt;Array&gt;.name</td>
<td>Name of the data classification. Data type: String</td>
</tr>
</tbody>
</table>

This example retrieves a list of all available data classifications.

```javascript
var dcm = new global.ScopedDCManager();
gs.info(dcm.getAllDataClasses());
```

Output:

```json
[
{
"parent": {
  "sys_id": "a9670fc773fc1010ae8dd21efaf6a735",
  "name": "Confidential"
},
  "sys_id": "348107b951d71010f877f3f178e7dd0d",
  "name": "Personally identifiable information"
},
{
  "sys_id": "a9670fc773fc1010ae8dd21efaf6a735",
  "name": "Confidential"
},
{
  "sys_id": "59b7070b73fc1010ae8dd21efaf6a764",
  "name": "Restricted"
},
{
  "sys_id": "11d60fc773fc1010ae8dd21efaf6a744",
  "name": "Internal"
},
{
  "sys_id": "f5b4cf4773fc1010ae8dd21efaf6a766",
  "name": "Public"
}
]
ScopedDCManager - getClassification(String dictEntries)
Retrieves all data classifications for the specified dictionary entries.
Requires the admin, data_classification_admin, or data_classification_auditor role.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dictEntries</td>
<td>String</td>
<td>The sys_ids of the records you want to retrieve classifications for. The sys_ids are from the Dictionary [sys_dictionary] table. Entered as a comma-separated list enclosed in a string.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;</td>
<td>JSON object containing each dictionary entry’s sys_id with an array of its associated data classes. If there are no associated data classifications, it returns a message describing the result of the operation. Data classifications can be organized into parent-child relationships. If there are parent data classifications, they are identified in the result. Data type: Object</td>
</tr>
<tr>
<td>&lt;Object&gt;.parent</td>
<td>Entry for a parent data classification. Data type: Object</td>
</tr>
</tbody>
</table>

```json
{
  "sys_dictionary_sys_id": [ 
    {
      "parent": {Object},
      "sys_id": "String",
      "name": "String"
    }
  ]
}
```

```json
"parent": {
  "sys_id": "String",
```
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;name&quot;: &quot;String&quot;</td>
<td></td>
</tr>
<tr>
<td>}</td>
<td></td>
</tr>
</tbody>
</table>

<Object>.parent.sys_id of the parent data classification from the Data Classification [data_classification] table.
Data type: String

<Object>.parent.name name of the parent data classification.
Data type: String

<Object>.sys_id Sys_id of the data classification from the Data Classification [data_classification] table.
Data type: String

<Object>.name Name of the data classification.
Data type: String

This example retrieves the data classifications for a dictionary entry.

```javascript
var dcm = new global.ScopedDCManager();
gs.info(dcm.getClassification("445de0a6dba30300efc57416bf9619b0"));
```

Output:

```json
{
    "445de0a6dba30300efc57416bf9619b0": [
    {
        "parent": {
            "sys_id": "a9670fc773fc1010ae8dd21e6af6a735",
            "name": "Confidential"
        },
        "sys_id": "348107b951d71010f877f3f178e7dd0d",
        "name": "Personally identifiable information"
    }
    ]
}
```

**DatasetDefinition - Global**

Identifies a set of records including a table name, columns, and row selection criteria to use as input for ML training algorithms. Datasets do not contain the actual data.
The DatasetDefinition API requires the Predictive Intelligence plugin (com.glide.platform_ml) and is provided within the sn_ml namespace. For information, see Predictive Intelligence.

Use the dataset to estimate mutual information PredictabilityEstimate or train data specified by an Encoder. You can also use the dataset to train data specified by one of the following solution types:

- ClassificationSolution
- ClusteringSolution
- RegressionSolution
- SimilaritySolution

For usage guidelines, refer to Using ML APIs.

**DatasetDefinition - DatasetDefinition(Object)**

Creates an instance of the DatasetDefinition class, enabling you to define a dataset by table name, fields, and query.

Create your dataset definition by passing a table and a list of fields. You can also pass a query to restrict datasets to include rows with specific characteristics. Once created, a DatasetDefinition object cannot be modified.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config</td>
<td>Object</td>
<td>JavaScript object containing the dataset definition properties.</td>
</tr>
<tr>
<td>config.tableName</td>
<td>String</td>
<td>Name of the table for the dataset. For example, &quot;tableName&quot; : &quot;Incident&quot;.</td>
</tr>
<tr>
<td>config.fieldNames</td>
<td>Array</td>
<td>Optional. List of field names from the specified table as strings. For example, &quot;fieldNames&quot; : [&quot;short_description&quot;, &quot;priority&quot;]. Default: All fields</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>config.fieldDetails</td>
<td>Array</td>
<td>Optional. List of JavaScript objects that specify field properties. Use this property to force machine learning algorithms to interpret fields as being a specific type. You do not need to get field details for every field listed in the <code>fieldNames</code> property. All details must correspond with a field listed in the <code>fieldNames</code> array.</td>
</tr>
<tr>
<td>config.fieldDetails.name</td>
<td>String</td>
<td>Name of the field defining the type of information to restrict this dataset to. If used, this field name must match the corresponding name listed in the <code>fieldNames</code> property.</td>
</tr>
<tr>
<td>config.fieldDetails.type</td>
<td>String</td>
<td>Machine-learning field type. Specifying the data type forces the ML trainer to interpret a field as having that type. If no data type is specified, the system determines the type. Supported types:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>nominal</strong>: ML interprets this field as containing classes or categories.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>numeric</strong>: ML interprets this field as containing numbers.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>text</strong>: ML interprets this field as containing text.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>These types identify data types from a machine learning perspective. The ML type might differ from the type listed in the source table. A field can be a string type, but its purpose can be to encode a nominal value. For example, t-shirt sizes such as “XL”, “L”, or…</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config.encodedQuery</td>
<td>String</td>
<td>Optional. Encoded query string in standard Glide format. See Encoded query strings. You can construct the query to be absolute or relative. For example, your query can return rows for the previous 3 months (relative), or for the May through July period (absolute). Whether using an absolute or relative pattern, the data a definition identifies can change if the rows in the underlying table change.</td>
</tr>
</tbody>
</table>

The following example shows how to create a dataset definition.

```javascript
var myData = new sn_ml.DatasetDefinition(
  {
    'tableName' : 'incident',
    'fieldNames' : ['category', 'short_description', 'priority', 'assignment_group.name'],
    'fieldDetails' : [
      {
        'name' : 'category',
        'type' : 'nominal'
      },
      {
        'name' : 'short_description',
        'type' : 'text'
      }
    ],
    'encodedQuery' : 'sys_created_onONLast%20%20quarters@javascript:gs.beginningOfLast2Quarters()@javascript:gs.endOfLast2Quarters()^state=3'
  });
```

**DatasetDefinition - getEligibleFields(String capability)**

Returns a list of fields that are eligible as either input fields (features) or predicted fields regarding a solution of a given capability, for example, a classification solution. Eligibility is determined based on the fields having the appropriate glide data types.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>capability</td>
<td>String</td>
<td>Capability for which to retrieve fields eligible for training. This method currently only supports classification solutions, any other value for the capability throws a &quot;capability not supported&quot; exception. Valid values: &quot;classification&quot;</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Object containing eligible input field names and eligible output field names.</td>
</tr>
<tr>
<td></td>
<td>{ &quot;eligibleInputFieldNames&quot; : [Array], &quot;eligibleOutputFieldNames&quot; : [Array] }</td>
</tr>
<tr>
<td>&lt;Object&gt;.eligibleInputFieldNames</td>
<td>List of strings indicating input fields eligible for training. Data type: Array</td>
</tr>
<tr>
<td>&lt;Object&gt;.eligibleOutputFieldNames</td>
<td>List of strings indicating output fields eligible for training. Data type: Array</td>
</tr>
</tbody>
</table>

The following example shows how to display eligible fields for a classification solution.

```javascript
var myIncidentData = new sn_ml.DatasetDefinition({
  'tableName' : 'incident',
  'encodedQuery' : 'activeANYTHING'
});

var eligibleFields = JSON.parse(myIncidentData.getEligibleFields('classification'));

gs.print(JSON.stringify(eligibleFields, null, 2));
```

Output:
.DateTimeUtils - Global

DateTimeUtils class is a collection of date/time functions.
The DateTimeUtils class is provided via the Script Include DateTimeUtils.
The DateTimeUtils class can be used in any server-side script, and is available through GlideAjax.

DateTimeUtils - int8ToGlideDateTime(Number int64)

Converts Microsoft AD integer8 DateTime format into GlideDateTime format.

Integer8 is also known as Microsoft Filetime format. This method is commonly used when importing AD user's date fields, such as Expiration Date.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int64</td>
<td>Number</td>
<td>A 64-bit value representing the number of 100-nanosecond intervals since January 1, 1601 (UTC).</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDateTime</td>
<td>A GlideDateTime object set to the Integer8 date and time.</td>
</tr>
</tbody>
</table>
//convert and set account expiration date from AD
//this is an example that could be used in an LDAP import transform map to import the LDAP account
//expires attribute to a customer created u_account_expires GlideDateTime field
var dtUtil = new DateTimeUtils();
target.u_account_expires = dtUtil.int8ToGlideDateTime(source.u_accountexpires);

DateTimeUtils - msToGlideDateTime(Number milliseconds)
Convert milliseconds to a GlideDateTime object

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>The number of milliseconds</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDateTime</td>
<td>A GlideDateTime object</td>
</tr>
</tbody>
</table>

//example script to call the method from a client
Replace MILLISECONDSVALUE with your variable
var ga = new GlideAjax('DateTimeUtils');
ga.addParam('sysparm_name','msToGlideDateTime');
ga.addParam('sysparm_value', MILLISECONDSVALUE);
ga/XMLWait();
var newGDT = ga.getAnswer();

DecisionTableAPI - Scoped, Global
Use the DecisionTableAPI class to access Decision Tables data in scoped and global server-side scripts.
Access DecisionTableAPI methods using the sn_dt namespace. To learn more about Decision Tables, see Decision Tables.

DecisionTableAPI - DecisionTableAPI()
Instantiates a DecisionTableAPI object.
var dt = new sn_dt.DecisionTableAPI();

**DecisionTableAPI - getAll()**

Returns all decision tables from the Decision Tables [sys_decision] table.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Object  | All decision tables and their fields from the Decision Tables [sys_decision] table. Each decision table contains these key-value pairs:  
  - distinctAnswers: Array. Answer records associated with the decision table. Each record contains these key-value pairs:  
    - valid: Boolean. True if the record exists in the system; otherwise false.
    - label: String. Answer record label.
    - value: String. Sys ID of the answer record.
    - table: String. Table containing the answer record.
  - referenceQualifier: String. Used for internal purposes.
  - inputs: Array. Decision inputs from the Decision Inputs [sys_decision_input] table associated with the decision table. Each record contains these key-value pairs:  
    - searchField: String. Used for internal purposes.
    - defaultValue: String. Default value for the input.
    - show_ref_finder: Boolean. Used for internal purposes.
    - use_dependent: Boolean. Used for internal purposes. |
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>◦</td>
<td>type: String. Input data type.</td>

DecisionTableAPI - getAnswers(String decisionID)

Returns the answers associated with the specified decision table. An answer is a record on any table associated with a Decision [sys_decision_question] record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>decisionID</td>
<td>String</td>
<td>Sys ID of the Decision Table record from the Decision Tables [sys_decision] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Answer records associated with the decision table. Each record contains these key-value pairs:</td>
</tr>
<tr>
<td></td>
<td>• valid: Boolean. True if the record exists in the system; otherwise false.</td>
</tr>
<tr>
<td></td>
<td>• label: String. Answer record label.</td>
</tr>
<tr>
<td></td>
<td>• value: String. Sys ID of the answer record.</td>
</tr>
<tr>
<td></td>
<td>• table: String. Table containing the answer record.</td>
</tr>
</tbody>
</table>

Format: JSON

```javascript
var dt = new sn_dt.DecisionTableAPI();
var response = dt.getAnswers("3c4464a7b701230034d1da23ee11a993");
gs.info(JSON.stringify(response));
```

Output:

```json
"result": [{
  "valid": true,
  "label": "CAB Approval",
  "value": "45358a5db701230034d1da23ee11a938",
  "table": "chg_approval_def"
}]
```
**DecisionTableAPI - getDecision(String decisionID, Map inputs)**

Evaluates a decision table based on the provided inputs and returns an answer. If no inputs are provided, returns the first default answer found.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>decisionID</td>
<td>String</td>
<td>Sys ID of the Decision Table record from the Decision Tables [sys_decision] table.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Optional. Input values for the Decision Inputs [sys_decision_input] table associated with the provided decision table. Use the value of the Column name field as the key. The data type of the value must match the Decision Input Type field. If no inputs are provided, returns the first default answer found.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>The correctly evaluated Answer record associated with the decision table. An answer record is a record from the table defined in the Decision [sys_decision_question] record Answer table field. If no inputs are provided, returns the first default answer found. If no default or correctly evaluated answers are found, returns an error.</td>
</tr>
</tbody>
</table>

```javascript
var dt = new sn_dt.DecisionTableAPI();
var inputs = new Object();
inputs['age'] = 25;
var response = dt.getDecision('26eea7a9dba07300efc65404ce961961', inputs);
```

**DecisionTableAPI - getDecisions(String decisionID, Map inputs)**

Evaluates a decision table based on the provided inputs and returns all correctly evaluated answers. If no inputs are provided, returns all default answers.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>decisionID</td>
<td>String</td>
<td>Sys ID of the Decision Table record from the Decision Tables [sys_decision] table.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Optional. Input values for the Decision Inputs [sys_decision_input] table associated with the provided decision table. If no inputs are provided, returns all default answers.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Answer records in GlideRecord format. An answer record is a record on any table associated with a Decision [sys_decision_question] record. If no inputs are provided, returns all default answers. If no default or correctly evaluated answers are found, returns an error.</td>
</tr>
</tbody>
</table>

```javascript
var dt = new sn_dt.DecisionTableAPI();
var input = new Object();
input['age'] = 25;
var response = dt.getDecisions('5b06ce5db701230034d1da23ee11a965', input);
```

**DecisionTableAPI - getDecisionTable(String decisionID)**

Returns a single decision table from the Decision Tables [sys_decision] table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>decisionID</td>
<td>String</td>
<td>Sys ID of the Decision Table record from the Decision Tables [sys_decision] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Decision table from the Decision Tables [sys_decision] table. Each decision table contains these key-value pairs.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>

DecisionTableAPI - getInputs(String decisionID)

Returns the decision inputs from the Decision Inputs [sys_decision_input] table associated with the passed in decision table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>decisionID</td>
<td>String</td>
<td>Sys ID of the Decision Table record from the Decision Tables [sys_decision] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Object | Decision inputs from the Decision Inputs [sys_decision_input] table associated with the decision table. You can find the inputs associated with a decision table using the Decision Inputs related list in the Decision Tables [sys_decision] table. Inputs contain these key-value pairs.  
  • searchField: String. Used for internal purposes.  
  • defaultValue: String. Default value for the input.  
  • show_ref_finder: Boolean. Used for internal purposes.  
  • use_dependent: Boolean. Used for internal purposes. |
Returns (continued)

```

**DecisionTableAPI - getQuestions(String decisionID)**

Returns the decisions from the Decision [sys_decision_question] table associated with the passed in decision table.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>decisionID</td>
<td>String</td>
<td>Sys ID of the Decision Table record from the Decision Tables [sys_decision] table.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Decisions from the Decision [sys_decision_question] table associated with the decision table. You can find the decisions associated with a decision table using the Decisions related list in the Decision Tables [sys_decision] table. Decision records contain these key-value pairs.</td>
</tr>
<tr>
<td></td>
<td>• defaultAnswer: Boolean. True if this decision is the default for the decision table; otherwise false.</td>
</tr>
<tr>
<td></td>
<td>• condition: String. Conditions required to reach this decision. The fields available for the condition are the decision inputs that are associated with this decision table.</td>
</tr>
<tr>
<td></td>
<td>• answer: Object. Answer record associated with the decision. Answer objects contain these key-value pairs.</td>
</tr>
<tr>
<td></td>
<td>◦ valid: Boolean. True if the record exists in the system; otherwise false.</td>
</tr>

    "id": "2764a4a7b701230034d1da23ee11a989",
    "label": "Requires CAB Approval",
    "order": 0
}]
}
```

**Document - Scoped, Global**

The Document API provides methods to initialize a PDF, add content, and close the PDF. After adding content, the document can be attached to a target record.

This API is part of the ServiceNow PDF Generation Utilities plugin (com.snc.apppdfgenerator) and is provided within the sn_pdfgeneratorutils namespace. The plugin is activated by default.

This API depends on the a suite of classes to build various elements comprising a PDF.

- **Cell** – Creates a Cell object as a cell in a table. You can use this API to format the cell and include additional blocks, such as paragraphs and images.

- **Color** – Creates a Color object used to define color attributes that you can apply to elements in a PDF: such as cells, tables, and lines.

- **Image** – Creates an Image object representing an image and its layout insert in a PDF. Enables defining attributes such as scale, alignment, and border color.

- **Line** – Creates a Line object using methods to draw a line in a PDF.
• **Paragraph** – Creates a Paragraph object representing a block of text in a PDF.

• **PdfPage** – Creates a PdfPage object representing a PDF page and its attributes; such as size, width, and color.

• **Style** – Creates a style for defining properties such as font size, border, and alignment. You can apply the same style to multiple objects simultaneously.

• **Table** – Creates a Table object to add to a PDF document. Defines the data to use in each cell and sets styles, margins, and alignment.

The following example shows how to create a basic PDF using the Document API and several components, such as a table, cell, and paragraph. The result is a list of Incidents from the Incident [incident] table listed in a PDF. You can test this example in your instance if you replace `<sys_id>` with the sys_id of an incident record.

```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("A4");
var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);

var whiteColor = sn_pdfgeneratorutils.Color([1,1,1]);
var greyColor = sn_pdfgeneratorutils.Color([0.8,0.8,0.8]);
var headerBgColor = new sn_pdfgeneratorutils.Color([0.4,0.6,0.8]);

// Query the Incident table
var gr = new GlideRecord("incident");
gr.query();

// declare table by providing width array and Boolean for large table
var table = new sn_pdfgeneratorutils.Table(true, [70,200], false);

var headerStyle = new sn_pdfgeneratorutils.Style;
headerStyle setBackgroundColor(headerBgColor);
headerStyle.setTextAlignment("text-center");
headerStyle.setBold();
headerStyle.setFontColor(whiteColor);

var nParagraph = new sn_pdfgeneratorutils.Paragraph("Number");
var sParagraph = new sn_pdfgeneratorutils.Paragraph("Short Description");

var hdrCell1 = new sn_pdfgeneratorutils.Cell;
var hdrCell2 = new sn_pdfgeneratorutils.Cell;
```
The PDF attachment is listed in the Attachments [sys_attachment] table.
Document - Document(PdfPage pageSize)

Instantiates a Document object and generates a PDF document.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageSize</td>
<td>PdfPage</td>
<td>PDF page size.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>PDF document.</td>
</tr>
</tbody>
</table>

The following example shows how to create a Document object and return a PDF.

```javascript
var pageSize = new sn_pdfs generatorutils.PdfPage("A4");
var document = new sn_pdfs generatorutils.Document(pageSize);
```
Document – addAndStartNewPage()

Adds a page to the document by terminating the current page and creating a new one.

Additional methods for adding a new page in a document:

- addNewPage() – Adds a new blank page to the document. Use to force a page break to start a new chapter or section in your document.
- addNewPageAtIndex() – Adds a new page at the specified index of the document. For example, setting the index to 6 inserts a page six or inserts the page at the position of the existing page six in a document. The original page six becomes page seven.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to add a new page to a document. For a document usage example, see Document API.

```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("LETTER");
var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);

var para1 = new sn_pdfgeneratorutils.Paragraph("This text lands on the first page.");
var para2 = new sn_pdfgeneratorutils.Paragraph("This text lands on the new page.");
document.addParagraph(para1);
document.addAndStartNewPage();
document.addParagraph(para2);

// save pdf as attachment to target record in the Incident table
document.saveAsAttachment("incident", "<record_sys_id>", "newPage.pdf");
```
**Document – addAuthor(String author)**

Adds a name to the author field in PDF document properties.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>author</td>
<td>String</td>
<td>Name of the document’s author.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to add a name to the author field in PDF document properties. For a document usage example, see `Document` API.

```javascript
var author = "John Do";
document.addAuthor(author);
```

**Document – addImage(Image image)**

Adds an image to a document.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>image</td>
<td>Image</td>
<td>Image to add to a document.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to add an image to a document. For a document usage example, see `Document` API.

```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("LETTER");
var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);

// declare image using sys attachment
var image = new sn_pdfgeneratorutils.Image("<imgAttachment_sys_id>");
```
// add the image to the doc
document.addImage(image);

document.saveAsAttachment("incident", "<record_sys_id>", "docWithImage.pdf");

**Document – addNewLine()**

Adds a new empty line to the document.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

The following example shows how to add a new line to a document. For a document usage example, see **Document** API.

```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("A4");

var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);

document.addNewLine();
```

**Document – addNewPage()**

Adds a new blank page to the document. Use to force a page break to start a new chapter or section in your document.

Additional methods for adding a new page in a document:

- **addAndStartNewPage()** – Adds a page to the document by terminating the current page and creating a new one.

- **addNewPageAtIndex()** – Adds a new page at the specified index of the document. For example, setting the index to 6 inserts a page six or inserts the page at the position of the existing page six in a document. The original page six becomes page seven.
The following example shows how to add a new blank page to a document. For a document usage example, see Document API.

Usage:
```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("A4");
var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);

document.addNewPage();
```

**Document – addNewPageAtIndex( Number index )**

Adds a new page at the specified index of the document. For example, setting the index to 6 inserts a page six or inserts the page at the position of the existing page six in a document. The original page six becomes page seven.

Additional methods for adding a new page in a document:
- ```addAndStartNewPage()``` – Adds a page to the document by terminating the current page and creating a new one.
- ```addNewPage()``` – Adds a new blank page to the document. Use to force a page break to start a new chapter or section in your document.
The following example shows how to add a new PDF page to position 6 of a document. For a document usage example, see Document API.

```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("A4");

var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);

var index = 6;

document.addNewPageAtIndex(index);
```

### Document – addParagraph(Paragraph paragraph)

Adds a paragraph to a document.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paragraph</td>
<td>Paragraph</td>
<td>Block of text provided as a paragraph object.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to add a paragraph to a document. For a document usage example, see Document API.

```javascript
var para = "Lorem ipsum dolor sit amet.";

document.addParagraph(para);
```

### Document – addTable(Table table)

Adds a table to a document.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Table</td>
<td>Table to be inserted into the document.</td>
</tr>
</tbody>
</table>
The following example shows how to add a table to a document. See the Table API for more details on how to define a table. For a document usage example, see Document API.

```javascript
var table = new sn_pdffgeneratorutils.Table([70,200], false);
document.addTable(table);
```

**Document – close()**

Closes a document.

The following example shows how to close a document. For a document usage example, see Document API.

```javascript
var pageSize = new sn_pdffgeneratorutils.PdfPage("A4");
var document = new sn_pdffgeneratorutils.Document.createDocument(pageSize);
document.close();
```

Creates a document with the specified page size.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("A4");
var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);
```

**Document – getPageCount()**

Gets the number of pages in the document.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of pages in the document.</td>
</tr>
</tbody>
</table>

The following example shows how to get the page count of a nine-page document. For a document usage example, see Document API.

```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("A4");
var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);
var count = document.getPageCount();
gs.info("The number of pages is "+ count);
```

Output:

```
The number of pages is 9
```

**Document – getPageSize()**

Gets the default page size of the document.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| String   | Value of the default page size set using the PdfPage API. Possible values:  
- A4 – 595 x 842 points  
- EXECUTIVE – 522 x 756 points  
- LETTER – 612 x 792 points  
- LEDGER – 792 x 1224 points |

The following example shows how to get the page size of a document. For a document usage example, see Document API.

```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("A4");
var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);
var pagesize = document.getPageSize();
```

Document – isClosed()

Indicates whether a document is closed or open.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Flag that indicates whether a document is open or closed. Valid values:</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>• true: Document is closed.</td>
<td></td>
</tr>
<tr>
<td>• false: Document is open.</td>
<td></td>
</tr>
<tr>
<td>Default: true</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to get the page size of a document. For a document usage example, see Document API.

```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("A4");

var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);

var closed = document.isClosed();
```

**Document – saveAsAttachment(String tableName, String tableSysId, String fileName)**

Attaches the document file to the specified target table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table on which to attach the document.</td>
</tr>
<tr>
<td>tableSysId</td>
<td>String</td>
<td>Sys_id of the record on which to attach the document.</td>
</tr>
<tr>
<td>fileName</td>
<td>String</td>
<td>Name of the document to attach.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

The following example shows how to attach a document to an incident record. For a document usage example, see Document API.
Document – setBaseDirection(String direction)

Sets the base text flow direction to reorder from based on character recognition

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>direction</td>
<td>String</td>
<td>Text flow direction. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LEFT_TO_RIGHT: Order text flow left to right. The text direction is only</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reordered if left-to-right language characters are detected.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• RIGHT_TO_LEFT: Order text flow right to left. The text direction is only</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reordered if right-to-left language characters are detected.</td>
</tr>
</tbody>
</table>

Default: LEFT_TO_RIGHT

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

The following example shows how to set text flow left to right. For a document usage example, see Document API.

```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("A4");
var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);
document.setBaseDirection("RIGHT_TO_LEFT");
```

Document – setMargins(Number topMargin, Number rightMargin, Number bottomMargin, Number leftMargin)

Sets the page margin sizes in the document.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>topMargin</td>
<td>Number</td>
<td>Height of the top margin in points.</td>
</tr>
<tr>
<td>rightMargin</td>
<td>Number</td>
<td>Width of the right margin in points.</td>
</tr>
<tr>
<td>bottomMargin</td>
<td>Number</td>
<td>Height of the bottom margin in points.</td>
</tr>
<tr>
<td>leftMargin</td>
<td>Number</td>
<td>Width of the left margin in points.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set page margins in a document. For a document usage example, see [Document API](#).

```javascript
var pageSize = new sn_pdfgeneratorutils.PdfPage("A4");
var document = new sn_pdfgeneratorutils.Document.createDocument(pageSize);
document.setMargins(72,36,36,36);
```

### DocumentListEntryService - Scoped, Global

Provides methods for maintaining document templates in a document list.

This API requires the Document Management plugin (com.snc.platform_document_management) and is provided within the `sn_doc_services` namespace. For information, see [Document Services](#).

Before using the methods in this API, add a document template with its version and create a document list. Use the `SystemDocumentListEntry` API to add or remove documents from a document list.

Before using the methods in this API, you must add a document with its default version and create a document list.

- **SystemDocument** – Define a document object.
- **DocumentService** – Add, update, or delete a document.
- **DocumentVersionService** – Add, update, or delete a document version.
• **SystemDocumentList** – Define a document list.

• **DocumentListService** – Add, update, or delete a document list.

To define a document as a template:

• Define the document object setting the **SystemDocument – template()** method to true. Create or update the document record with the methods in the **DocumentService API**.

• Select the Template check box of a document in the Documents [ds_document] table.

**DocumentListEntryService** - **DocumentListEntryService()**

InstANTIATES a DocumentListEntryService object.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

The following example shows how to instantiate a **DocumentListEntryService** object.

```javascript
var s = new sn_doc_services.DocumentListEntryService();
```

**DocumentListEntryService** - **createDocumentListEntry(SystemDocumentListEntry entry)**

Adds a document template entry to a document list.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>entry</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>{</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&quot;message&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;request_id&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;status&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>&lt;Object&gt;.message</td>
<td>Message confirming success or error.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.status</td>
<td>Status indicating whether the operation is successful. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• success - The operation was successful.</td>
</tr>
<tr>
<td></td>
<td>• failure – The operation was not successful. The message provides details.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

The following example shows how to define a document entry and add it to a document list. See also SystemDocumentListEntry.

```javascript
var docListEntry = new
  sn_doc_services.SystemDocumentListEntry('21afdde2460fc10f877a6fed1c2b0dd');
docListEntry.document("9acd7efa24587410f877a6fed1c2b060");
docListEntry.description('birth certificate');

var dlEntrySvc = new sn_doc_services.DocumentListEntryService();
gs.info(JSON.stringify(dlEntrySvc.createDocumentListEntry(docListEntry), null, 2));
```

Output:

```json
{
   "message": "Create List Entry , List Entry sysId : d3f0b13624e8fc10f877a6fed1c2b0d9 is successful. ",
   "request_id": "d3f0b13624e8fc10f877a6fed1c2b0d9",
   "status": "success"
}
```
DocumentListEntryService - deleteDocumentListEntry(String listEntryId)

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Success or error message.</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;message&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;status&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td>&lt;Object&gt;.message</td>
<td>Message confirming success or error.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.status</td>
<td>Status indicating whether the operation is successful. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• success - The operation was successful.</td>
</tr>
<tr>
<td></td>
<td>• failure – The operation was not successful. The message provides details.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

The following example shows how to delete a document list record. See also SystemDocumentList.

```javascript
var listEntryId = 'd3f0b13e24e8fc10f877a6fed1c2b0d9';

var dlEntrySvc = new sn_doc_services.DocumentListEntryService();
gs.info(JSON.stringify(dlEntrySvc.deleteDocumentListEntry(listEntryId), null, 2));
```

Output:
{  
  "message": "Deleting an entry for the given documentListEntrySysId : d3f0b13624e8fc10f877a6fed1c2b0d9 is successful.",
  "status": "success"
}

**DocumentListEntryService- updateDocumentListEntry(String listEntryId, SystemDocumentListEntry entry)**

Updates the field values of an existing document list entry.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>entry</td>
<td>SystemDocumentListEntry</td>
<td>One or more properties representing fields of a document list entry object.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Success or error message.</td>
</tr>
<tr>
<td>&lt;Object&gt;.message</td>
<td>Message confirming success or error. Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.status</td>
<td>Status indicating whether the operation is successful. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• success - The operation was successful.</td>
</tr>
<tr>
<td></td>
<td>• failure – The operation was not successful. The message provides details.</td>
</tr>
</tbody>
</table>
The following example shows how to update a document list entry description. See also `SystemDocumentListEntry`.

```javascript
var listEntryId = 'd3f0b13624e8fc10f877a6fed1c2b0d9';

var entry = new sn_doc_services.SystemDocumentListEntry();
entry.description('description update');

var dlEntrySvc = new sn_doc_services.DocumentListEntryService();
gs.info(JSON.stringify(dlEntrySvc.updateDocumentListEntry(listEntryId, entry), null, 2));
```

Output:

```json
{
  "message": "Updating an entry for the given documentListEntrySysId: d3f0b13624e8fc10f877a6fed1c2b0d9 is successful.",
  "request_id": "d3f0b13624e8fc10f877a6fed1c2b0d9",
  "status": "success"
}
```

### DocumentListService - Scoped, Global

Provides methods for creating, deleting, and updating a document list.

This API requires the Document Management plugin (com.snc.platform_document_management) and is provided within the `sn_doc_services` namespace. For information, see Document Services.

The Document Management plugin also supports creating lists of document templates to associate with your document. For example, a job application requiring multiple documents such as a diploma, ID, or passport. After you add your document list, you can add document templates:

- `SystemDocumentListEntry` – Define a document template list entry.
- `DocumentListEntryService` – Add or remove a document template list entry.

To define a document as a template:
• Define the document object setting the `SystemDocument - template()` method to true. Create or update the document record with the methods in the `DocumentService` API.

• Select the Template check box of a document in the Documents [ds_document] table.

The following APIs enable you to define and manage documents:

• `SystemDocument` – Define a document object.

• `DocumentService` – Add, update, or delete a document.

To define a document as a template:

• Define the document object setting the `SystemDocument - template()` method to true. Create or update the document record with the methods in the `DocumentService` API.

• Select the Template check box of a document in the Documents [ds_document] table.

See also `SystemDocumentList`.

**DocumentListService - createDocumentList(SystemDocumentList doc)**

The Document Management plugin also supports creating lists of document templates to associate with your document. For example, a job application requiring multiple documents such as a diploma, ID, or passport. After you add your document list, you can add document templates:

• `SystemDocumentListEntry` – Define a document template list entry.

• `DocumentListEntryService` – Add or remove a document template list entry.

Use the `createDocumentsFromList()` method to create documents from the document template list.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>doc</td>
<td>SystemDocumentList</td>
<td>One or more properties representing fields of a new record. The name property is required and can be set using the <code>SystemDocumentList constructor or name()</code> method.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td></td>
<td>{</td>
<td></td>
</tr>
</tbody>
</table>
|            |   "message": "String",
|            |   "request_id": "String",
|            |   "status": "String"
|            | }                                                                                                                                                                                                       |
| <Object>.message | Message confirming success or error.                                                                                                         |
|            | Data type: String                                                                                                                           |
|            | Data type: String                                                                                                                           |
| <Object>.status | Status indicating whether the operation is successful. Possible values:                                                                   |
|            | • success - The operation was successful.                                                                                                   |
|            | • failure – The operation was not successful. The message provides details.                                                                                                                               |
|            | Data type: String                                                                                                                           |

The following example shows how to create a document list. See also SystemDocumentList.

```javascript
var dL = new sn_doc_services.SystemDocumentList('My document list');

// Define the document list field
dL.description('description');

var docList = new sn_doc_services.DocumentListService();
gs.info(JSON.stringify(docList.createDocumentList(dL), null, 2));
```

Output:

```json
{
   "message": "Create List for the given name : My document list, List sysId : b2c021a9246b3c10f877a6fed1c2b0b1 is successful."
}
DocumentListService - createDocumentsFromList(String listSysId, String tableName, String tableSysId)

Creates documents from a list of document templates.

⚠️ **Note:** Before using this method, create a document template list using the `createDocumentList()` method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table containing the record on which add a list of document template references.</td>
</tr>
<tr>
<td>tableSysId</td>
<td>String</td>
<td>Sys_id of the record containing the content from which to add a list of document template references.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Success or error message.</td>
</tr>
<tr>
<td>&lt;Object&gt;.message</td>
<td>Message containing the number of document templates in the document list. Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.status</td>
<td>Status indicating whether the operation is successful.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>• success - The operation was successful.</td>
</tr>
<tr>
<td></td>
<td>• failure – The operation was not successful. The <strong>message</strong> provides details.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

The following example shows how add a list of document template references to a record. The documentation is added to a record in the Incidents [incident] table.

```javascript
var result = new sn_doc_services.DocumentListService().createDocumentsFromList('21afddea2460fc10f877a6fed1c2b0dd', 'incident', 'd7158da0c0a8016700eef46c8d1f3661');
gs.info(JSON.stringify(result, null, 2));
```

**Output:**

```javascript
{
    "message": "Created 1 document references for the given table name: incident, table sysId : d7158da0c0a8016700eef46c8d1f3661 with list SysId 21afddea2460fc10f877a6fed1c2b0dd",
    "request_id": "21afddea2460fc10f877a6fed1c2b0dd",
    "status": "success"
}
```

**DocumentListService - deleteDocumentList(String listSysId)**

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Success or error message.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| {}         | {  "message": "String",
    "request_id": "String",
    "status": "String"
        }                                                                                                                                 |
| <Object>.message | Message confirming success or error.                                                                                                          |
|        | Data type: String                                                                                                                              |
|        | Data type: String                                                                                                                              |
| <Object>.status | Status indicating whether the operation is successful. Possible values:                                                                      |
|        | • success - The operation was successful.                                                                                                     |
|        | • failure – The operation was not successful. The message provides details.                                                                      |
|        | Data type: String                                                                                                                              |

The following example shows how to delete a document list record. See also SystemDocumentList.

```javascript
var docListID = 'b2c021a924683c10f877a6fed1c2b0b1';

var docListSvc = new sn_doc_services.DocumentListService();
gs.info(JSON.stringify(docListSvc.deleteDocumentList(docListID), null, 2));
```

Output:

```javascript
{
    "message": "Delete List for the given sysId : b2c021a924683c10f877a6fed1c2b0b1 is successful.",
    "request_id": "b2c021a924683c10f877a6fed1c2b0b1",
    "status": "success"
}
```

**DocumentListService - DocumentListService()**

Instantiates a DocumentListService object.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to instantiate a `DocumentListService` object. See also `SystemDocumentList`.

```javascript
var s = new sn_doc_services.DocumentListService();
```

**DocumentListService - updateDocumentList(String docSysId, SystemDocumentList doc)**

Updates the field values of an existing document list.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>doc</td>
<td>SystemDocument</td>
<td>One or more properties representing document list fields to be updated.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Success or error message.</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;message&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;request_id&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;status&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>&lt;Object&gt;.message</td>
<td>Message confirming success or error.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.status</td>
<td>Status indicating whether the operation is successful. Possible values:</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>The operation was successful.</td>
</tr>
<tr>
<td>failure</td>
<td>The operation was not successful. The message provides details.</td>
</tr>
</tbody>
</table>

Data type: String

The following example shows how to update a document list name and description. See also SystemDocumentList.

```javascript
var docListID = 'b2c021a924683c10f877a6fed1c2b0b1';

var docListUpdate = new sn_doc_services.SystemDocumentList();
docListUpdate.name('name change');
docListUpdate.description('description update');

var docListSvc = new sn_doc_services.DocumentListService();
gs.info(JSON.stringify(docListSvc.updateDocumentList(docListID , docListUpdate), null, 2));
```

Output:

```json
{
  "message": "Update List for the given sysId : b2c021a924683c10f877a6fed1c2b0b1 is successful. ",
  "request_id": "b2c021a924683c10f877a6fed1c2b0b1",
  "status": "success"
}
```

**DocumentReferenceService - Scoped, Global**

Provides methods for managing document references within a target table, such as the Incidents [incident] or Knowledge [kb_knowledge] table. You can use document references to associate information with a record.

This API requires the Document Management plugin (com.snc.platform_document_management) and is provided within the sn_doc_services namespace. For information, see Document Services.

The following APIs enable you to define and manage documents:

- **SystemDocument** – Define a document object.
- **DocumentService** – Add, update, or delete a document.
DocumentReferenceService - DocumentReferenceService()

Instantiates a DocumentReferenceService object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to instantiate a DocumentReferenceService object.

```javascript
var result = new sn_doc_services.DocumentReferenceService();
```

DocumentReferenceService - addDocumentReference(String docSysId, String targetTable, String tableSysId)

Adds a document reference to a target table record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetTable</td>
<td>String</td>
<td>Name of the target table on which to provide a document reference.</td>
</tr>
<tr>
<td>tableSysId</td>
<td>String</td>
<td>Sys_id of the target table record to which the document reference is to be added.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

```javascript
{
  "message": "String",
  "status": "String"
}
```
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;Object&gt;.message</code></td>
<td>Message confirming success or error. If successful, includes the sys_id of the record the document reference was added to. Data type: String</td>
</tr>
</tbody>
</table>
| `<Object>.status` | Status indicating whether the operation is successful. Possible values:  
  • success - The operation was successful.  
  • failure – The operation was not successful. The `message` provides details. Data type: String                                                   |

The following example shows how to add a document reference to a record in the Incidents `[incident]` table.

```javascript
var docReference = new sn_doc_services.DocumentReferenceService();

var result = docReference.addDocumentReference("<docSysId>", "incident", ",<tableSysId>");

gs.info(JSON.stringify(result, null, 2));
```

Output:

```javascript
{
  "message": "Adding an entry to DocumentReference for the given docId to target table: incident, sysId : <tableSysId> is successful.",
  "status": "success"
}
```

**DocumentReferenceService - removeDocumentReference(String docSysId, String targetTable, String tableSysId)**

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetTable</td>
<td>String</td>
<td>Name of the table containing the document reference. This information is listed with the document in the Document References [ds_document_reference] table.</td>
</tr>
<tr>
<td>tableSysId</td>
<td>String</td>
<td>Sys_id of the record from which the document is referenced. You can find related information listed with the document in the Document References [ds_document_reference] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Success message. Error message otherwise.</td>
</tr>
<tr>
<td>&lt;Object&gt;.message</td>
<td>Message confirming success or error. If successful, includes the sys_id of the record the document reference was removed from.</td>
</tr>
<tr>
<td>&lt;Object&gt;.status</td>
<td>Status indicating whether the operation is successful. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• success - The operation was successful.</td>
</tr>
<tr>
<td></td>
<td>• failure – The operation was not successful. The message provides details.</td>
</tr>
</tbody>
</table>

The following example shows how to remove a document reference from a record in the Incidents [incident] table.
var docReference = new sn_doc_services.DocumentReferenceService();

var result = docReference.removeDocumentReference("<docSysId>", "incident",
  "<tableSysId>");

gs.info(JSON.stringify(result, null, 2));

Output:

{
  "message": "Deleting an entry to DocumentReference for the given docId to target table : incident, sysId : <tableSysId> is successful.",
  "status": "success"
}

DocumentService - Scoped, Global

Provides methods for creating, deleting, and updating a document.

This API requires the Document Management plugin (com.snc.platform_document_management) and is provided within the sn_doc_services namespace. For information, see Document Services.

A document is a collection of information about a document record. The methods used to create or update a record modify fields using the SystemDocument object.

Document content is managed using versions. The following APIs enable you to define and manage document versions:

- SystemDocumentVersion – Define a document version as the source of the document content. Each version is an element containing the document content and is provided using a single URL or attachment. An attachment can only be added in the Document Versions [ds_document_version] table UI and not with the API.

- DocumentVersionService – Document content is managed using versions.

Use the DocumentReferenceService API to manage documents referenced in a target table, such as the Incidents [incident] or Knowledge [kb_knowledge] table.

The Document Management plugin also supports creating lists of document templates to associate with your document. For example, a job application requiring multiple documents such as a diploma, ID, or passport.

- DocumentListService – Add or remove a document template list.
• **SystemDocumentListEntry** – Define a document template list entry.
• **DocumentListEntryService** – Add or remove a document template list entry.

**DocumentService - DocumentService()**
Instantiates a `DocumentService` object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to instantiate a `DocumentService` object.

```csharp
var s = new sn_doc_services.DocumentService();
```

**DocumentService - createDocument(SystemDocument doc)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>doc</td>
<td><code>SystemDocument</code></td>
<td>One or more properties representing fields of a new record. The name property is required and can be set using the <code>SystemDocument</code> constructor or <code>name()</code> method.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;Object&gt;.message</code></td>
<td>Message confirming success or error. Possible values:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
|      | • Create document sysId : `<sys_id>` is successful.  
|      | • Document Name is mandatory and should be valid.  
|      | • Document Name is mandatory and it should not be null or empty.  
|      | • `<SystemDocument` property requiring sys_id input> withSysId: "<sys_id>" does not exist  
|      | Data type: String |

Data type: String

<Object>.statusStatus indicating whether the operation is successful. Possible values:  
• success - The operation was successful.  
• failure – The operation was not successful. The message provides details.  
Data type: String

The following example shows how to populate `SystemDocument` object properties and create a new document record.

```javascript
var d = new sn_doc_services.SystemDocument('My document');

// Define the document fields
var reviewers = '62826bf03710200044e0bfc8bcbe5df1,a8f98bb0eb32010045e1a5115206fe3a';
d.description('description');
d.classification('restricted');
d.state('review');
d.department('93b25282c0a8000b0b55c8ab34e2f1e6');
d.template(false);
d.type('policy');
d.reviewers(reviewers);
d.audience('external');
```
var s = new sn_doc_services.DocumentService();
gs.info(JSON.stringify(s.createDocument(d), null, 2));

Output:
{
  "message": "Create document sysId : 1040420224503410f877a6fed1c2b031 is successful.",
  "request_id": "1040420224503410f877a6fed1c2b031",
  "status": "success"
}

DocumentService - deleteDocument(String docSysId)

Removes a document record from the Documents [ds_document] table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Success or error message.</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;message&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;request_id&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;status&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>&lt;Object&gt;.message</td>
<td>Message confirming success or error.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.status</td>
<td>Status indicating whether the operation is successful. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• success - The operation was successful.</td>
</tr>
<tr>
<td></td>
<td>• failure – The operation was not successful. The message provides details.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to delete an existing document record.

```javascript
var docid = "<sys_id>";
var svc = new sn_doc_services.DocumentService();
gs.info(JSON.stringify(svc.deleteDocument(docid), null, 2));
```

Output:

```json
{
  "message": "Delete document sysId : <sys_id> is successful.",
  "request_id": "<sys_id>",
  "status": "success"
}
```

DocumentService - updateDocument(String docSysId, SystemDocument doc)

Updates the field values of an existing document record.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>doc</td>
<td>SystemDocument</td>
<td>One or more properties representing document fields to be updated.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Success or error message.</td>
</tr>
</tbody>
</table>

```json
{
  "message": "String",
  "request_id": "String",
  "status": "String"
}
```
## Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td><code>&lt;Object&gt;.status</code></td>
<td>Status indicating whether the operation is successful.</td>
</tr>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>• success - The operation was successful.</td>
</tr>
<tr>
<td></td>
<td>• failure – The operation was not successful. The message provides details.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

The following example shows how to change a document name. See also SystemDocument.

```javascript
var dId = "19aab54e24103410f877a6fed1c2b03d";
var d = new sn_doc_services.SystemDocument();
d.name("c22.txt");
var s = new sn_doc_services.DocumentService();
gs.info(JSON.stringify(s.updateDocument(dId, d), null, 2));
```

Output:

```javascript
{
  "message": "Update document sysId : 19aab54e24103410f877a6fed1c2b03d is successful.",
  "request_id": "19aab54e24103410f877a6fed1c2b03d",
  "status": "success"
}
```

### DocumentVersionService - Scoped, Global

Provides a service for creating and deleting document versions. Each version is an element containing the document content and is provided using a single URL or attachment. An attachment can only be added in the Document Versions [ds_document_version] table UI and not with the API.

This API requires the Document Management plugin (com.snc.platform_document_management) and is provided within the sn_doc_services namespace. For information, see Document Services.
Before creating a document version, you must first define and add a document record.

- **SystemDocument** – Define a document object.
- **DocumentService** – Add, update, or delete a document.

**DocumentVersionService - DocumentVersionService()**

Instantiates a `DocumentVersionService` object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to instantiate a `DocumentVersionService` object.

```javascript
var versionSvc = new sn_doc_services.DocumentVersionService();
```

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

```json
{
    "message": "String",
    "request_id": "String",
    "status": "String"
}
```
## Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;Object&gt;.message</code></td>
<td>Message confirming success or error. If successful, includes the sys_id of the document record and the sys_id of its new document version. Data type: String</td>
</tr>
</tbody>
</table>
| `<Object>.status`         | Status indicating whether the operation is successful. Possible values:  
  • success - The operation was successful.  
  • failure – The operation was not successful. The message provides details. Data type: String                                                                 |

The following example shows how to populate SystemDocumentVersion object properties and create a new document version. See also SystemDocumentVersion.

```javascript
var versionDefinition = new sn_doc_services.SystemDocumentVersion('491efbee24187410f877a6fed1c2b0a9');
versionDefinition.type('url');
versionDefinition.url('http://one/1.0');
var versionSvc = new sn_doc_services.DocumentVersionService();
gs.info(JSON.stringify(versionSvc.createDocumentVersion(versionDefinition), null, 2));

Output:
```

```javascript
{
  "message": "Adding an entry to DocumentVersion for the given docId : 491efbee24187410f877a6fed1c2b0a9, sysId : d5a340d9242cf810f877a6fed1c2b069 is successful.",
  "request_id": "d5a340d9242cf810f877a6fed1c2b069",
  "status": "success"
}
```
DocumentVersionService - deleteDocumentVersion(String docVersionSysId)

Deletes a document version.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Success message. Error message otherwise.</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;message&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;status&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>&lt;Object&gt;.message</td>
<td>Message confirming success or error. If successful, includes the sys_id of the deleted document version.</td>
</tr>
<tr>
<td>&lt;Object&gt;.status</td>
<td>Status indicating whether the operation is successful. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• success - The operation was successful.</td>
</tr>
<tr>
<td></td>
<td>• failure – The operation was not successful. The message provides details.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

The following example shows how to delete an existing document version.

```javascript
var vId = "<versionSysId>";
var versionSvc = new sn_doc_services.DocumentVersionService();

gs.info(JSON.stringify(versionSvc.deleteDocumentVersion(vId), null, 2));
```

Output:

```javascript
{
   "message": "Deleting an entry to DocumentVersion for the given documentVersionSysId : , sysId : <versionSysId> is successful.",
```
DSCScriptableAPI - Global

Provides methods for checking the health of your domain configuration for the instance.

The DSCScriptableAPI is part of the Domain Separation Center dashboard and is available in the SNC global namespace.

The com.glide.domain.msp_extensions.installer plugin must be activated for Domain Separation Center dashboard availability.

DSCScriptableAPI - chkDataInvalidDomainForTables(String tableNames)

Checks a list of comma-separated tables for invalid domains.

View records that reference invalid domains in the Domain Log [syslog_domain] table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableNames</td>
<td>String</td>
<td>Comma-separated list of table names.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GUID of any invalid references; OK otherwise</td>
</tr>
</tbody>
</table>

```
var dsc = new SNC.DSCScriptableAPI();
dsc.chkDataInvalidDomainForTables('task, sys_user');
```

DSCScriptableAPI - chkDataInvalidPathForTables(String tableNames)

Checks a list of comma-separated tables for invalid domain paths.

Records that have an invalid domain path are logged in the syslog_domain table.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Comma-separated list of table names.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GUID if there are invalid paths; OK otherwise</td>
</tr>
</tbody>
</table>

```javascript
var dsc = new SNC.DSCScriptableAPI();
dsc.chkDataInvalidPathForTables('task, sys_user');
```

DSCScriptableAPI - DSCScriptableAPI()

Instantiates a new DSCScriptable object.

DurationCalculator - Global

Provides methods for calculating durations and due dates.

DurationCalculator - calcDuration(Number seconds)

Calculates an end date and time based on current start date and time and passed in duration (seconds).

This method also sets the `this.endDateDateTime`, `this.seconds`, and `this.totalSeconds` properties with the updated values. Prior to calling this method, you must call `setStartDateTime()` with the start time to use in the computation.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seconds</td>
<td>Number</td>
<td>Number of seconds to add to the start date and time to compute the end date and time, seconds, and total seconds values.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>False if the input value is not a number.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2020-05-01 00:00:00");
var dc = new DurationCalculator();
dc.setStartDateTime(gdt);

if(!dc.calcDuration(2*24*3600)){ // 2 days
  gs.log("*** Error calculating duration");
  return;
}
var secs = dc.getSeconds();
var totalSecs = dc.getTotalSeconds();

gs.print("***SCHEDULE DURATION: SECS=" + secs + " TOTALSECS=" + totalSecs + " ENDTIME = " + endDateTime);
```

Output

```
***SCHEDULE DURATION: SECS=172800 TOTALSECS=970534 ENDTIME = 2020-05-03 00:00:00
```

DurationCalculator - calcRelativeDueDate(GlideDateTime start, Number days, String endTime)

Calculates the due date starting at the passed in start time and adding the number of days using the current schedule and time zone.

Called from relative duration definitions, initiated by calcRelativeDuration(), as calculator.calcRelativeDueDate(calculator.startDateTime, days). Once the day that the work is due is determined, the method sets the time to the passed in endTime of that day. If there are not enough days left in the schedule, uses the last day in the schedule.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>GlideDateTime</td>
<td>GlideDateTime object that contains the start date for the computation.</td>
</tr>
<tr>
<td>days</td>
<td>Number</td>
<td>Number of days to add to the start date.</td>
</tr>
<tr>
<td>endTime</td>
<td>String</td>
<td>Time of day that the work is due on the computed due date. If blank,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>defaults to the end of the work day. Format: HH:mm:ss</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates if the completion date is within the schedule. Possible</td>
</tr>
<tr>
<td></td>
<td>values:</td>
</tr>
<tr>
<td></td>
<td>• true: Completion date is within the schedule.</td>
</tr>
<tr>
<td></td>
<td>• false: Completion date falls outside the schedule. Undefined if no</td>
</tr>
<tr>
<td></td>
<td>schedule was set prior to calling this method.</td>
</tr>
</tbody>
</table>

```javascript
var dc = new DurationCalculator();
var startTime = new GlideDateTime();

// Settings for calculations
// Optional: Specify the schedule to use for the following calculations
dc.setSchedule('08fcd0830a0a0b2600079f56b1adb9ae');
// Optional: Specify a different timezone to use
dc.setTimeZone("Los Angeles");
// Optional: Set a start date and time, otherwise the current time is assumed
dc.setStartDateTime("2020-04-10 08:00:00")
// Calculate end time, from number of seconds required in the schedule
dc.calcDuration(3*24*3600); // 3 days
dc.calcRelativeDueDate(startTime, "3", "07:00:00");
```

**DurationCalculator - calcRelativeDuration(String relativeDurationID)**
Calculates the duration using the specified relative duration script.
Upon completion, the `this.endDateTime` and `this.seconds` properties are set to indicate the results of the calculation.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>relativeDurationID</td>
<td>String</td>
<td>sys_id of relative duration schedule (table cmn_relative_duration).</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>The result of the duration script.</td>
</tr>
</tbody>
</table>

```javascript
var dc = new DurationCalculator();
dc.calcRelativeDuration('08fcd0830a0a1b2600074f56b1ad7cb');
```

### DurationCalculator - calcScheduleDuration(String startTime, String endTime)

Returns the duration between the `startTime` and the `endTime` within the already-specified schedule and optionally overridden timezone.

This method also sets `this.endDateTime`, `this.seconds`, and `this.totalSeconds` in the current schedule object.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startTime</td>
<td>String</td>
<td>Optional. Display value for the end time.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: Uses the current date and time (set using <code>setStartDateTime()</code>).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You must pass a placeholder if this parameter it not passed, such as</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>dur.calcScheduleDuration('', endDateTime)</code>;</td>
</tr>
<tr>
<td>endTime</td>
<td>String</td>
<td>Optional. Display value for the start time.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: Uses the current date and time (set using <code>setEndDateTime()</code>).</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Schedule duration. Returns 0 if endTime is before startTime. Unit: Seconds</td>
</tr>
</tbody>
</table>

```javascript
var dur = new DurationCalculator();

// Set 9-5 weekday schedule. This is the schedule in which endDateTime, seconds, and totalseconds is set
dur.setSchedule('08fcd0830a0a0b2600079f56b1ad9ae');
dur.calcScheduleDuration("2019-01-02 11:00:00", "2019-01-06 09:00:00");
var secs = dur.getSeconds();
var totalSecs = dur.getTotalSeconds();
var endDateTime = dur.getEndDateTime() + "";

gs.print("***SCHEDULE DURATION: SECS=\" + secs + " TOTALSECS=\" + totalSecs + " ENDTIME = \" + endDateTime);```

Output

```markdown
***SCHEDULE DURATION: SECS=97200 TOTALSECS=338400 ENDTIME = 2019-01-06 09:00:00
```

**DurationCalculator - calcScheduleDuration(GlideDateTime startTime, GlideDateTime endTime)**

Returns the duration between the startTime and the endTime within the already-specified schedule and optionally overridden timezone.

This method also sets this.endDateTime, this.seconds, and this.totalSeconds in the current schedule object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startTime</td>
<td>GlideDateTime</td>
<td>Optional. GlideDateTime object that contains the start time to use.  Default: Uses the current date and time (set using setStartDateTime()). You must pass a placeholder if this parameter it not passed, such as dur.calcScheduleDuration(&quot;&quot;, endDateTime);.</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>endTime</td>
<td>GlideDateTime</td>
<td>Optional. GlideDateTime object that contains the end time to use. Default: Uses the current date and time (set using setEndDateTime()).</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Schedule duration. Returns 0 if endTime is before startTime. Unit: Seconds</td>
</tr>
</tbody>
</table>

```javascript
var startDateTime = new GlideDateTime("2020-11-02 11:00:00");
// Instantiate a new GlideDateTime object which has the end date as the current date and time
var endDateTime = new GlideDateTime();
var dur = new DurationCalculator();

// Set 9-5 weekday schedule. This is the schedule in which endTime, seconds, and totalSeconds is set
dur.setSchedule('08fcd0830a0a0b2600079f56b1adb9ae');
dur.calcScheduleDuration(startDateTime, endDateTime);
var secs = dur.getSeconds();
var totalSecs = dur.getTotalSeconds();

gs.print("***SCHEDULE DURATION: SECS=" + secs + " TOTALSECS=" + totalSecs + " ENDTIME = " + endDateTime);
```

### Output

```text
***SCHEDULE DURATION: SECS=293734.24 TOTALSECS=970534 ENDTIME = 2020-11-13 16:35:34
```

**DurationCalculator** - Constructor for **DurationCalculator** class.
DurationCalculator - getEndDateTime()

Gets the `endDateTime` property that was set by `calcDuration/calcRelativeDuration`, indicating the end date and time for the duration.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDateTime</td>
<td>The end datetime.</td>
</tr>
</tbody>
</table>

```javascript
var dc = new DurationCalculator();
dc.calcDuration(52);
gs.print(dc.getEndDateTime());
```

2012-04-17 20:57:27

DurationCalculator - getSeconds()

Returns the `this.seconds` property that was set by `calcDuration/calcRelativeDuration`, indicating the total number of seconds of work to be performed for the duration.

This is the total work time, not the total time between start and end times and may be used to determine percentages of the work time.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The total work time, in seconds.</td>
</tr>
</tbody>
</table>

```javascript
var startDate = new GlideDateTime("2020-11-02 11:00:00");
// Instantiate a new GlideDateTime object which has the end date as the current date and time
var endDate = new GlideDateTime();
var dur = new DurationCalculator();

// Set 9-5 weekday schedule. This is the schedule in which endDate, seconds, and totalSeconds is set
dur.setSchedule('08fcd0830a0a0b2600079f56b1adb9ae');
dur.calcScheduleDuration(startDate, endDate);
var secs = dur.getSeconds();
var totalSecs = dur.getTotalSeconds();

gs.print("***SCHEDULE DURATION: SECS=" + secs + " TOTALSECS=" + totalSecs + " ENDTIME = " + endDate);
```

Output

```
***SCHEDULE DURATION: SECS=293734.24 TOTALSECS=970534 ENDTIME = 2020-11-13 16:35:34
```

**DurationCalculator - getTotalSeconds()**

Returns the `totalSeconds` value that was set by a call to `calculate(record)`.
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The total number of seconds.</td>
</tr>
</tbody>
</table>

```javascript
var startDateTime = new GlideDateTime("2020-11-02 11:00:00");
// Instantiate a new GlideDateTime object which has the end date as the current date and
time
var endDateTime = new GlideDateTime();
var dur = new DurationCalculator();

// Set 9-5 weekday schedule. This is the schedule in which endDateTime, seconds, and
totalseconds is set
dur.setSchedule('08fcd0830a0a0b2600079f56b1adb9ae');
dur.calcScheduleDuration(startDateTime, endDateTime);
var secs = dur.getSeconds();
var totalSecs = dur.getTotalSeconds();

gs.print("***SCHEDULE DURATION: SECS=\" + secs + " TOTALSECS=\" + totalSecs + " ENDTIME = \" +
endDateTime);```

Output

```
***SCHEDULE DURATION: SECS=293734.24 TOTALSECS=970534 ENDTIME = 2020-11-13 16:35:34
```

**DurationCalculator - isAfter(GlideDateTime dt, String tm)**

Compares the passed in time to the time value in the passed in GlideDateTime object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dt</td>
<td>GlideDateTime or String</td>
<td>Either a GlideDateTime object or a display value date and time to compare to the passed in tm value. If you pass a display value date and time, the method converts it to a GlideDateTime object.</td>
</tr>
<tr>
<td>tm</td>
<td>String</td>
<td>Display value for the time to compare against the time value in the GlideDateTime object. Assumes same date. Format: HH:mm:ss.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates if the passed in time value (tm) is after the time in</td>
</tr>
<tr>
<td></td>
<td>the GlideDateTime object (dt). Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: tm is after dt.</td>
</tr>
<tr>
<td></td>
<td>• false tm is not after dt.</td>
</tr>
</tbody>
</table>

```javascript
var dc = new DurationCalculator();
gs.print(dc.isAfter("2020-04-10 08:00:00", "09:00:00"));

*** Script: true

DurationCalculator - setSchedule(String schedId, String timezone)
Sets the schedule and time zone to use for calculating the due date.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedId</td>
<td>String</td>
<td>Sys_id of the schedule to set. Located in the Schedule [cmn_schedule] table.</td>
</tr>
<tr>
<td>timezone</td>
<td>String</td>
<td>Optional. Time zone to set. Default: User’s time zone.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var startDateTime = new GlideDateTime("2020-11-02 11:00:00");
// Instantiate a new GlideDateTime object which has the end date as the current date and
time
var endDateTime = new GlideDateTime();
var dur = new DurationCalculator();
```
// Set 9-5 weekday schedule. This is the schedule in which endDateTime, seconds, and
totalseconds is set
dur.setSchedule('08fcd0830a0a0b2600079f56b1adb9ae');
dur.calcScheduleDuration(startDateTime, endDateTime);
var secs = dur.getSeconds();
var totalSecs = dur.getTotalSeconds();

gs.print("***SCHEDULE DURATION: SECS=\" + secs + " TOTALSECS=\" + totalSecs + " ENDTIME = " +
endDateTime);

Output

***SCHEDULE DURATION: SECS=293734.24 TOTALSECS=970534 ENDTIME = 2020-11-13 16:35:34

DurationCalculator - setStartDateTime(String start)
Sets the start date and time for the duration calculations.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>String</td>
<td>Display value for the start time in GMT for subsequent calculations.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var dc = new DurationCalculator();
dc.setStartDateTime("2020-04-10 08:00:00")

DurationCalculator - setStartDateTime(GlideDateTime description)
Sets the start date and time for the duration calculations.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>GlideDateTime</td>
<td>GlideDateTime object that contains the start time in GMT for subsequent calculations.</td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var startDateTime = new GlideDateTime("2020-11-02 11:00:00");
var dur = new DurationCalculator();
// Set 9-5 weekday schedule.
dur.setSchedule('08fcd0830a0a0b260079f56b1ad9ae');
dur.setStartDateTime(startDateTime);
```

### DurationCalculator - setTimeZone(String timezone)

Sets the time zone to use for calculating the due date.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timezone</td>
<td>String</td>
<td>Value of the time zone.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var dc = new DurationCalculator();
dc.setTimeZone("Los Angeles");
```

### DynamicTranslation - Client

The **DynamicTranslation** API provides methods that translate text, in real time, into multiple languages using translation service providers. This API is available for both standard clients and Angular-based Service Portal clients.

In addition, you can use this API to detect the language of a specific string and check whether the **DynamicTranslation** methods are enabled for a translation service. Use this API to create a seamless localization experience for your user interface, enabling one interface to service multiple countries.
Currently this API supports three translation service providers: Microsoft Azure Translator Service, IBM Watson Translator Service, and Google Cloud Translator Service. You can also configure other translation services within your instance and then use the DynamicTranslation API to translate your text.

To use this API you must activate the Dynamic Translation plugin. For information on this plugin and additional information on Dynamic Translation, refer to Dynamic translation overview. Also, to use this API in a Service Portal widget, you must inject the dynamicTranslation service into the widget client script function.

⚠️ Note: The name of the class to use in Service Portal clients is dynamicTranslation, while the name of the class to use in standard clients is DynamicTranslation.

**DynamicTranslation - getDetectedLanguage(String text, Object parms)**

Detects the language of the passed in text.

If you pass in a translator, the method uses that translation service to detect the source language. Otherwise, the detection is performed by the default translation service. Ensure that the text strings that you provide contain enough verbiage to enable proper language detection.

In addition to the detected language, the response contains a confidence level of the detection, along with other possible language alternatives. If a translator is not passed in, the method also returns the default translation service used to detect the language.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>String</td>
<td>Text to use to detect the language.</td>
</tr>
<tr>
<td>parms</td>
<td>Object</td>
<td>Optional. JSON object that contains additional translation parameters.</td>
</tr>
<tr>
<td>parms.translator</td>
<td>String</td>
<td>Translation service to use to detect the language of a string. Translation services are configured under the Translator Configuration menu and located in the Translator Configuration [sn_dt_translator_configuration] table.</td>
</tr>
</tbody>
</table>

## Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Possible values - not case-sensitive:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Google</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Microsoft</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- IBM</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- &lt;custom&gt;</td>
</tr>
</tbody>
</table>

**Note:** To use custom translation services you must first configure the translation service in your instance. For details, see Integrate with a translation service provider.

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alternatives</td>
<td>Array of objects that describe other languages that might also be a match. Data type: Array</td>
</tr>
</tbody>
</table>

```json
"alternatives": [
  {
    "code": "String",
    "confidence": "String",
    "name": "String"
  }
]
```

<table>
<thead>
<tr>
<th>alternatives.code</th>
<th>Language code of the alternative language. Data type: String</th>
</tr>
</thead>
<tbody>
<tr>
<td>alternatives.confidence</td>
<td>Float value indicating the confidence level of the alternative language. Value is between zero and one. The lower the value, the lower the confidence level.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alternatives.name</td>
<td>Language code of the alternative language. Data type: String</td>
</tr>
<tr>
<td>detectedLanguage</td>
<td>Description of the detected language. Data type: Object</td>
</tr>
<tr>
<td>detectedLanguage.code</td>
<td>Language code of the detected language. Data type: String</td>
</tr>
<tr>
<td>detectedLanguage.confidence</td>
<td>Float value indicating the confidence level of the alternative language. Value is between zero and one. The lower the value, the lower the confidence level. Data type: String</td>
</tr>
<tr>
<td>detectedLanguage.name</td>
<td>Language code of the detected language. Data type: String</td>
</tr>
<tr>
<td>translator</td>
<td>Translation service used to detect the language. Data type: String</td>
</tr>
</tbody>
</table>

Error messages

The following are error messages that the method may return and indications as to the error's root cause.

- Text ("text" field) is missing or invalid. (40000): The text to detect the language is either missing or not a string.
- Dynamic Translation plugin is not installed. (40001): The Dynamic Translation API was invoked without activating the com.glide.dynamic_translation plugin. For

</tr>
</tbody>
</table>

This example shows code that detects a string in English using IBM's translation service in a standard client script.

```
var detectedResponse = DynamicTranslation.getDetectedLanguage('Please detect the language of this text', {'translator':'IBM'}).then(function(res) {console.log(res); }, function(res) {console.log(res); } );
```

Output:

```
detectedResponse {
    detectedLanguage: {
        "code": "en", "confidence": "1", "name": "en" }
alternatives:
    [ {
        "code": "vi", "confidence": "0.86", "name": "vi" },
        { "code": "id", "confidence": "0.86", "name": "id" }
    ]
}
```

This example shows a client script that throws an error when an invalid translation service is passed in.
var detectedResponse = DynamicTranslation.getDetectedLanguage('Please detect the language of this text',{"translator":123}).then(function(res) {console.log(res); }, function(res) {console.log(res); });

Output:

{"code":40003,"message":"Translator ("translator" field) is invalid"}

This example shows code that detects a string in English using IBM's translation service in a Service Portal widget client script. Note that the name of the class is dynamicTranslation not DynamicTranslation.

var detectedResponse = dynamicTranslation.getDetectedLanguage('Please detect the language of this text',{"translator':'IBM'}).then(function(res) {console.log(res); }, function(res) {console.log(res); });

Output:

detectedResponse {
  detectedLanguage:
    { "code": "en", "confidence": "1", "name": "en" }
  alternatives:
    [
      { "code": "vi", "confidence": "0.86", "name": "vi" },
      { "code": "id", "confidence": "0.86", "name": "id" }
    ]
}

This example shows a Service Portal widget client script that throws an error when an invalid translation service is passed in.

var detectedResponse = dynamicTranslation.getDetectedLanguage('Please detect the language of this text',{"translator":123}).then(function(res) {console.log(res); }, function(res) {console.log(res); });

Output:

{"code":40003,"message":"Translator ("translator" field) is invalid"}

DynamicTranslation - getDetectedLanguages(Array texts, Object parms)
Detects the languages of the passed in text strings.

If you pass in a translator, the method uses that translation service to detect the source language. Otherwise, the detection is performed by the default translation service. Ensure that the text strings that you provide contain enough verbiage to enable proper language detection.
In addition to the detected language, the response contains a confidence level of the detection, along with other possible language alternatives. If a translator is not passed in, the method also returns the default translation service used to detect the language.

When calling this method from a portal client script, use the class name `dynamicTranslation`; such as `dynamicTranslation.getTranslations()`. When calling it from a platform client script, use the class name `DynamicTranslation`; such as `DynamicTranslation.getTranslations()`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parms</td>
<td>Object</td>
<td>Optional. JSON object that contains additional translation parameters.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;parms&quot;: {</td>
</tr>
<tr>

</tr>
<tr>
<td>• Unknown error occurred. (40051): Default error thrown when the error doesn’t fall in to any other category.</td>
<td></td>
</tr>
<tr>
<td>• Text (&quot;text&quot; field) has exceeded its maximum length. (40052): The text that was passed in for language detections exceeds the maximum length supported by the corresponding translation service.</td>
<td></td>
</tr>
<tr>
<td>• Request is not authorized because credentials are missing or invalid (40055): The credentials configured for the translation service in Connections &amp; Credentials are not valid. For information on connections and credentials, see Dynamic translation overview.</td>
<td></td>
</tr>
</tbody>
</table>

This example shows code from a portal client script that detects English as the language of the passed-in strings using the Microsoft translation service.

```javascript
var detectedResponse = dynamicTranslation.getDetectedLanguages(["First text string language to detect", "Second text string language to detect"], {"translator": "Microsoft"}).then(function(res) {console.log(res);}, function(res) {console.log(res);});
gs.info(JSON.stringify(detectedResponse));
```

Output

```javascript
{
 "translator":"Microsoft",
 "status":"Success",
 "detections": [
 { 
 "isError":false,
 "detectedLanguage":{"name":"en", "code":"en", "confidence":"1"},
 "alternatives":[
 {"name":"id", "code":"id", "confidence":"0.83"},
 {"name":"ms", "code":"ms", "confidence":"0.83"}
 ]
 },
}
```
This example shows code in a portal client script that returns a Partial status when two text strings are passed in and one of them is invalid. To use this code example in a platform client script, change `dynamicTranslation.getDetectedLanguages` to `DynamicTranslation.getDetectedLanguages`.

```javascript
var detectedResponse = dynamicTranslation.getDetectedLanguages(
    ["First text string language to detect", ""],
    {"translator": "Microsoft"}
).then(function(res) {
    console.log(res);
},
function(res) {
    console.log(res);
});
gs.info(JSON.stringify(detectedResponse));
```

Output

```javascript
{
    "translator": "Microsoft",
    "status": "Partial",
    "detections": [
        {
            "isError": false,
            "detectedLanguage": {"name": "en", "code": "en", "confidence": "1"},
            "alternatives": [
                {"name": "fr", "code": "fr", "confidence": "0.83"},
                {"name": "id", "code": "id", "confidence": "0.83"}
            ]
        },
        {
            "isError": true,
            "code": "40000",
            "message": "Text is missing or invalid"
        }
    ]
}
```
This example shows code from a portal client script that throws an error when an invalid translation service is passed in. To use this code example for a platform client script, change `dynamicTranslation.getDetectedLanguages` to `DynamicTranslation.getDetectedLanguages`.

```javascript
var detectedResponse = dynamicTranslation.getDetectedLanguages(["First text string language to detect", "Second text string language to detect"], {"translator": "123"}).then(function(res) {console.log(res); }, function(res) {console.log(res); });
gs.info(JSON.stringify(detectedResponse));
```

Output

```json
{"code":40003,"message":"Translator ("translator" field) is invalid","status":"Error"}
```

**DynamicTranslation - getTranslation(String textToTranslate, Object parms)**

Translates the passed in text to one or more languages.

The method uses translation services, such as Microsoft Azure Translator Service, IBM Watson Translator Service, and Google Cloud Translator Service, to perform the translation. If you do not pass in translation parameters, the method uses the system default.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>textToTranslate</td>
<td>String</td>
<td>Text to translate.</td>
</tr>
<tr>
<td>parms</td>
<td>Object</td>
<td>Optional. JSON object that contains additional translation parameters.</td>
</tr>
</tbody>
</table>

  "parms": {
  "additionalParameters":
  {Object},
  "sourceLanguage": "String",
  "targetLanguages": [Array],
  "translator": "String"
  }

| parms.additionalParameters | Object | Optional. Array of JSON objects. Each object contains key-value pairs that provide additional information for performing the translation. |
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>additionalParameters</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>parameterName</strong></td>
<td>String</td>
<td>Optional. Key name. Valid values:</td>
</tr>
<tr>
<td><strong>parameterValue</strong></td>
<td>String</td>
<td>Optional. Value of the associated key. Valid values:</td>
</tr>
<tr>
<td><strong>sourceLanguage</strong></td>
<td>String</td>
<td>Optional. Language code of the source text. Default: Translation service detects the source language.</td>
</tr>
<tr>
<td><strong>targetLanguages</strong></td>
<td>Array</td>
<td>Optional. List of language codes to use to translate the text. Default: User preferred language.</td>
</tr>
<tr>
<td><strong>translator</strong></td>
<td>String</td>
<td>Optional. Translation service to use to translate the text (not case-sensitive). Valid values:</td>

</tbody>
</table>

This example shows the translation of plain text content from English (detected) into French and Italian using Microsoft's translation service in a standard client script.
DynamicTranslation.getTranslation("Translate this text using platform from client", {  "targetLanguages": ["fr", "it"],  "additionalParameters": [{    "parameterName": "texttype",    "parameterValue": "plain"  }],  "translator": "Microsoft"}).then(function(res){console.log(res);}, function(res){console.log(res);});

Response:

{"translations":[
  {
    "targetLanguage":"it",
    "translatedText":"Tradurre questo testo utilizzando la piattaforma dal client"
  },
  {
    "targetLanguage":"fr",
    "translatedText":"Traduire ce texte en utilisant la plate-forme du client"
  }
],
"translator":"Microsoft",
"detectedLanguage":{"code":"en","name":"en"}
}

This example shows a client script that throws an error when an invalid target language is passed in.

DynamicTranslation.getTranslation("Translate this text using platform from client", {  "targetLanguages": ["123"],  "additionalParameters": [{    "parameterName": "texttype",    "parameterValue": "plain"  }],  "translator": "Microsoft"}).then(function(res){console.log(res);}, function(res){console.log(res);});

Response:

{"code":"40054","message":"Target language is invalid"}

This example shows the translation of plain text content from English (detected) into French and Italian using Microsoft's translation service in a Service Portal widget client script. Note that the name of the class is dynamicTranslation not DynamicTranslation.
dynamicTranslation.getTranslation("Translate this text using platform from client", {
    "targetLanguages": ["fr", "it"],
    "additionalParameters": [{
        "parameterName": "texttype",
        "parameterValue": "plain"
    }],
    "translator": "Microsoft"
}).then(function(res){console.log(res);}, function(res){console.log(res);});

Response:

{"translations": [  
   {  
        "targetLanguage": "it",
        "translatedText": "Tradurre questo testo utilizzando la piattaforma dal client"
   },
   {  
        "targetLanguage": "fr",
        "translatedText": "Traduire ce texte en utilisant la plate-forme du client"
   }
],
"translator": "Microsoft",
"detectedLanguage": {"code": "en", "name": "en"}
}

This example shows a Service Portal widget client script that throws an error when an invalid target language is passed in

dynamicTranslation.getTranslation("Translate this text using platform from client", {
    "targetLanguages": [123],
    "additionalParameters": [{
        "parameterName": "texttype",
        "parameterValue": "plain"
    }],
    "translator": "Microsoft"
}).then(function(res){console.log(res);}, function(res){console.log(res);});

Response:

{"code": "40054", "message": "Target language is invalid"}

DynamicTranslation - getTranslations(Array texts, Object parms)
Translates the passed in text strings to one or more languages.
The method uses translation services, such as Microsoft Azure Translator Service, IBM Watson Translator Service, and Google Cloud Translator Service, to perform the translation. If you do not pass in translation parameters, the method uses the system default.

When calling this method from a portal client script, use the class name `dynamicTranslation`; such as `dynamicTranslation.getTranslations()`. When calling it from a platform client script, use the class name `DynamicTranslation`; such as `DynamicTranslation.getTranslations()`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>texts</td>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>valid. For information on connections and credentials, see Dynamic translation overview.</td>
</tr>
<tr>
<td></td>
<td>• Text cannot be translated to target languages. (40056): The specified translation service is not able to translate the passed in text into the specified target languages.</td>
</tr>
</tbody>
</table>

This example shows code in a portal client script that translates a list of text strings into French and Italian using the Microsoft translation service.

dynamicTranslation.getTranslations(
	"Translate first text using portal from client",
	"Translate second text using portal from client"), {
	"targetLanguages": ["fr", "it"],
	"additionalParameters": [
		"parameterName": "texttype",
		"parameterValue": "plain"
	],
	"translator": "Microsoft"
}).then(function(res){console.log(res);}, function(res){console.log(res);});

Response:

{
	"translations": [
	{
		"isError":false,
		"textTranslations": [
		{
			"targetLanguage": "it",
			"translatedText": "Tradurre il primo testo utilizzando il portale dal client"
		},
		{
			"targetLanguage": "fr",
			"translatedText": "Traduire le premier texte à l’aide du portail à partir du client"
		}
	],
	"detectedLanguage": {"name": "en", "code": "en"}
	}
}
This example shows a portal client script that returns a Partial status when one of the two passed in text strings is invalid. To use this code example for a platform client script, change `dynamicTranslation.getTranslations` to `DynamicTranslation.getTranslations`.

```javascript
dynamicTranslation.getTranslations(['Translate first text using portal from client', ''], {
  'targetLanguages': ['fr', 'it'],
  'additionalParameters': [{
    'parameterName': 'texttype',
    'ParameterValue': 'plain'
  }],
  'translator': 'Microsoft'
}).then(function(res){console.log(res);}, function(res){console.log(res);});
```

Response:

```json
{
  "translations":{
    {
      "isError":false,
      "textTranslations":{
        {
          "targetLanguage": "it",
          "translatedText": "Tradurre il primo testo utilizzando il portale dal client"
        }
      }
    }
  }
}
This example shows a portal client script that throws an error when an invalid translation service is passed in. To use this code example for a platform client script, change `dynamicTranslation.getTranslations` to `DynamicTranslation.getTranslations`.

```javascript
dynamicTranslation.getTranslations(
  [
    "Translate first text using portal from client",
    "Translate second text using portal from client"
  ],
  {
    "targetLanguages": ["fr", "it"],
    "additionalParameters": [{
      "parameterName": "texttype",
      "parameterValue": "plain"
    }],
    "translator": 123
  }).then(function(res){console.log(res);}, function(res){console.log(res);});
```

Response:

```json
{"code":40003,"message":"Translator ("translator" field) is invalid","status":"Error"}
```

**DynamicTranslation - isEnabled(String translator)**

Determines whether the various methods in the `DynamicTranslation API` are enabled for a translation service.

If you pass in a specific translation service, the method checks the method activation for that translation service; otherwise the method checks the default translation service.
When calling this method from a portal client script, use the class name `dynamicTranslation`; such as `dynamicTranslation.isEnabled()`. When calling it from a platform client script, use the class name `DynamicTranslation`; such as `DynamicTranslation.isEnabled()`.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>translator</td>
<td>String</td>
<td>Optional. Translation service to use to verify whether the methods are active. Translation services are configured under the Translator Configuration menu. Possible values - not case-sensitive:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Google</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Microsoft</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• IBM</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &lt;custom&gt;</td>
</tr>
</tbody>
</table>

**Note:** To use custom translation services you must first configure the translation service in your instance. For details, see [Integrate with a translation service provider](#).

Default: Default translation service.

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>batchDetection</td>

<tr>
<td></td>
<td>• Translator (&quot;translator&quot; field) is invalid. (40003): The passed in translator parameter is</td>
</tr>
<tr>
<td></td>
<td>not a string.</td>
</tr>
</tbody>
</table>

This example shows a client script that checks whether the `DynamicTranslation` methods are enabled for the Microsoft translation service. To use this code example for a platform client script, change `DynamicTranslation.getTranslations` to `dynamicTranslation.getTranslations`.

```javascript
DynamicTranslation.isEnabled('Microsoft').then(function(res){console.log(res);},
    function(res){console.log(res);});
```

Output:

```
{"detection":true,"batchTranslation":true,"batchDetection":true,"translation":true}
```

This example shows a client script that throws an error when an invalid translation service is passed in. To use this code example for a platform client script, change `DynamicTranslation.getTranslations` to `dynamicTranslation.getTranslations`.

```javascript
DynamicTranslation.isEnabled(123).then(function(res){console.log(res);},
    function(res){console.log(res);});
```
**DynamicTranslation - Scoped**

The DynamicTranslation API provides methods that translate text, in real time, into multiple languages using translation service providers.

In addition, you can use this API to detect the language of a specific string and check whether the DynamicTranslation methods are enabled for a translation service. Use this API to create a seamless localization experience for your user interface, enabling one interface to service multiple countries.

Currently this API supports three translation service providers: Microsoft Azure Translator Service, IBM Watson Translator Service, and Google Cloud Translator Service. You can also configure other translation services within your instance and then use the DynamicTranslation API to translate your text.

When using these methods in a server-side script, use the `sn_dt_api` namespace identifier. Before you are able to use this API, you must activate the DynamicTranslation (com.glide.dynamic_translation) plugin. For information on this plugin and additional information on Dynamic Translation, refer to [Dynamic translation overview](#).

**DynamicTranslation - getDetectedLanguage(String text, Object parms)**

Detects the language of the passed in text.

If you pass in a translator, the method uses that translation service to detect the source language. Otherwise, the detection is performed by the default translation service. Ensure that the text strings that you provide contain enough verbiage to enable proper language detection.

In addition to the detected language, the response contains a confidence level of the detection, along with other possible language alternatives. If a translator is not passed in, the method also returns the default translation service used to detect the language.

This example shows code in a server-side script that detects a string in English using IBM’s translation service.

```javascript
var detectedResponse = sn_dt_api.DynamicTranslation.getDetectedLanguage('Please detect the language of this text', {"translator":"IBM");
gs.info(JSON.stringify(detectedResponse));
```

**Output:**

```json
{
  detectedLanguage:
    { "code": "en", "confidence": "1", "name": "en" },
  alternatives:
    {
      { "code": "vi", "confidence": "0.86", "name": "vi" },
      { "code": "id", "confidence": "0.86", "name": "id" }
    }
}
```
This example shows a server script that throws an error when an invalid translation service is passed in.

```
var detectedResponse = sn_dt_api.DynamicTranslation.getDetectedLanguage('Please detect the language of this text', {"translator":123});
gs.info(JSON.stringify(detectedResponse));
```

Output:

```
{"code":"40003","message":"Translator ("translator" field) is invalid"}
```

**DynamicTranslation - getDetectedLanguages(Array texts, Object parms)**

Detects the languages of the passed in text strings.

If you pass in a translator, the method uses that translation service to detect the source language. Otherwise, the detection is performed by the default translation service. Ensure that the text strings that you provide contain enough verbiage to enable proper language detection.

In addition to the detected language, the response contains a confidence level of the detection, along with other possible language alternatives. If a translator is not passed in, the method also returns the default translation service used to detect the language.

This example shows code in a server script that detects English as the language of the passed-in strings using the Microsoft translation service.
var detectedResponse = sn_dt_api.DynamicTranslation.getDetectedLanguages(["First text string language to detect", "Second text string language to detect"], {"translator": "Microsoft"});
gs.info(JSON.stringify(detectedResponse));

Output

```
{
   "translator": "Microsoft",
   "status": "Success",
   "detections": [
   {
      "isError": false,
      "detectedLanguage": {"name": "en", "code": "en", "confidence": "1"},
      "alternatives": [
         {"name": "id", "code": "id", "confidence": "0.83"},
         {"name": "ms", "code": "ms", "confidence": "0.83"}
      ]
   },
   {
      "isError": false,
      "detectedLanguage": {"name": "en", "code": "en", "confidence": "1"},
      "alternatives": [
         {"name": "fr", "code": "fr", "confidence": "0.83"},
         {"name": "id", "code": "id", "confidence": "0.83"}
      ]
   }
   ]
}
```

This example shows code in a server script that returns a Partial status when two text strings are passed in and one of them is invalid.

var detectedResponse = sn_dt_api.DynamicTranslation.getDetectedLanguages(["First text string language to detect", ""], {"translator": "Microsoft"});
gs.info(JSON.stringify(detectedResponse));

Output

```
{
   "translator": "Microsoft",
   "status": "Partial",
   "detections": [
   {
      "isError": false,
      "detectedLanguage": {"name": "en", "code": "en", "confidence": "1"},
```
This example shows code in a server script that throws an error when an invalid translation service is passed in.

```javascript
var detectedResponse = sn_dt_api.DynamicTranslation.getDetectedLanguages(["First text string language to detect", "Second text string language to detect"], {"translator": "123");
gs.info(JSON.stringify(detectedResponse));
```

Output

```
{"code":"40003","message":"Translator ("translator" field) is invalid","status":"Error"
```

**DynamicTranslation - getTranslation(String textToTranslate, Object parms)**

Translates the passed in text to one or more languages.

The method uses translation services, such as Microsoft Azure Translator Service, IBM Watson Translator Service, and Google Cloud Translator Service, to perform the translation. If you do not pass in translation parameters, the method uses the system default.

<table>

</tr>
<tr>
<td></td>
<td>• Source language is invalid. (40053): The passed in <code>sourceLanguage</code> parameter contains a language code that is not supported by the corresponding translation service.</td>
</tr>
<tr>
<td></td>
<td>• Target language is invalid. (40054): One or more of the language codes passed in the <code>targetLanguages</code> parameter is not supported by the corresponding translation service.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Request is not authorized because credentials are missing or invalid (40055): The credentials configured for the translation service in Connections &amp; Credentials are not valid. For information on connections and credentials, see Dynamic translation overview.</td>
<td></td>
</tr>
<tr>
<td>• Text cannot be translated to target languages. (40056): The specified translation service is not able to translate the passed in text into the specified target languages.</td>
<td></td>
</tr>
</tbody>
</table>

This example shows a server script translating plain text from English (detected) into French and Italian using Microsoft’s translation service.

```javascript
try {
    gs.info(JSON.stringify(sn_dt_api.DynamicTranslation.getTranslation("Translate this text using platform from server", {
        "targetLanguages": ["fr", "it"],
        "additionalParameters": [{
            "parameterName": "texttype",
            "parameterValue": "plain"
        },
        "translator": "Microsoft"
    })));
} catch (error) {
    gs.info(error.message);
}
```

Response:

```javascript
[*translations*]:
{
    "targetLanguage": "it",
    "translatedText": "Tradurre questo testo utilizzando la piattaforma dal server"
},
{
    "targetLanguage": "fr",
    "translatedText": "Traduire ce texte en utilisant la plate-forme à partir du serveur"
},
"translator": "Microsoft",
```
This example shows a server script that throws an error when an invalid target language is passed in.

```javascript
try {
    gs.info(JSON.stringify(sn_dt_api.DynamicTranslation.getTranslation("Translate this text using platform from server", {
        "targetLanguages": ["123"],
        "additionalParameters": [{
            "parameterName": "texttype",
            "parameterValue": "plain"
        }],
        "translator": "Microsoft"
    }));
} catch (error) {
    gs.info(error.message);
}
```

Response:

```
{"code":"40054","message":"Target language is invalid"}
```

**DynamicTranslation - getTranslations(Array texts, Object parms)**

Translates the passed in text strings to one or more languages.

The method uses translation services, such as Microsoft Azure Translator Service, IBM Watson Translator Service, and Google Cloud Translator Service, to perform the translation. If you do not pass in translation parameters, the method uses the system default.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>texts</td>
<td>Array</td>
<td>List of text strings to translate.</td>
</tr>
<tr>
<td>parms</td>
<td>Object</td>
<td>Optional. JSON object that contains additional translation parameters.</td>
</tr>
</tbody>
</table>

"parms": {
    "additionalParameters": {
        "sourceLanguage": "String",
    },
...
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parms.additionalParameters</td>
<td>Object</td>
<td>Optional. Array of JSON objects. Each object contains key-value pairs that provide additional information for performing the translation.</td>
</tr>
<tr>
<td>parms.additionalParameters.parameterName</td>
<td>String</td>
<td>Optional. Key name. Valid values: • textype: Type of text to translate. For Microsoft Azure Translator Service only.</td>
</tr>
<tr>
<td>parms.additionalParameters.parameterValue</td>
<td>String</td>
<td>Optional. Value of the associated key. Valid values: • plain: Standard text string • html: HTML text string Default: plain</td>
</tr>
<tr>
<td>parms.sourceLanguage</td>
<td>String</td>
<td>Optional. Language code of the source text. Default: Translation service detects the source language.</td>
</tr>
<tr>
<td>parms.targetLanguages</td>
<td>Array</td>
<td>Optional. List of language codes to use to translate the text. The method returns translated text for each language code.</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parms.translator</td>
<td>String</td>
<td>Optional. Translation service to use to translate the text (not case-sensitive).</td>
</tr>
</tbody>
</table>

Valid values:
- Google
- Microsoft
- IBM
- <custom>

**Note:** To use custom translation services you must first configure the translation service in your instance. For details, see [Integrate with a translation service provider](#).

Default: Translation service configured in the Translator Configuration table.

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>Status of the response to the method call. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• Error</td>
</tr>
<tr>
<td></td>
<td>• Partial</td>
</tr>
<tr>
<td></td>
<td>• Success</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>translations</td>
<td>Array of objects that describe the language translations.</td>
</tr>
<tr>
<td>translations.isError</td>
<td>Flag that indicates whether the translation of the text resulted in an error.</td>
</tr>
<tr>
<td>translations.detectedLanguage</td>
<td>Description of the detected language.</td>
</tr>
<tr>
<td>translations.detectedLanguage.code</td>
<td>Language code of the detected language.</td>
</tr>
<tr>
<td>translations.detectedLanguage.name</td>
<td>Language code of the detected language.</td>
</tr>
</tbody>
</table>

- **Data type:** String
- **Data type:** Array
- **Data type:** Boolean
- **Data type:** Object
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>textTranslations</td>
<td>Array of objects. Description of the language used to translate the text string.</td>
</tr>
<tr>
<td>textTranslations.targetLanguage</td>
<td>Language code to which the source text was translated.</td>

<tr>
<td></td>
<td>• &lt;translator&gt; translator is not configured. (40004): The specified translation service is not configured in the Translator Configuration. For information on creating/modifying a translator configuration, see Create a translator configuration.</td>
</tr>
<tr>
<td></td>
<td>• &lt;translator&gt; translator is inactive. (40005): The specified translation service is not set to Active in the Translator Configuration. For information on creating/modifying a translator configuration, see Create a translator configuration.</td>
</tr>
<tr>
<td></td>
<td>• Additional parameters are invalid. (40006): The additional parameters that were passed are not an object.</td>
</tr>
<tr>
<td></td>
<td>• Target languages (&quot;targetLanguages&quot; field) are invalid. (40007): The targetLanguages parameter is passed in the call but is not valid for one of the following reasons:  ◦ Value is not an array  ◦ Array is empty  ◦ One or multiple of the entries is not a string</td>
</tr>
<tr>
<td></td>
<td>• Source language (&quot;sourceLanguage&quot; field) is invalid. (40008): The sourceLanguage parameter is passed in the call but the value is not a String.</td>
</tr>
</tbody>
</table>
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Maximum time limit has been exceeded. (40009): The operation took longer than the defined timeout value specified in the Translation Configuration. Default: 40 seconds.</td>
<td></td>
</tr>
<tr>
<td>• Request failed with multiple errors. (40010): Multiple errors occurred in the language detection call. For more information, refer to the response for each individual text string.</td>
<td></td>
</tr>
<tr>
<td>• <code>&lt;translator&gt;</code> translator is not configured for translation. (40012): The specified translation service is not configured for text translation in the Translator Configuration. For information on creating/modifying a translator configuration, see <a href="#">Create a translator configuration</a>.</td>
<td></td>
</tr>
<tr>
<td>• Translator configuration version is invalid. Migrate to v3. (40014): The associated version of the Translator Configuration for the specified translation service does not support the specified text translation method. For more information, see <a href="#">Migrate to version v3 of a translator configuration</a>.</td>
<td></td>
</tr>
<tr>
<td>• Unknown error occurred. (40051): Default error thrown when the error doesn’t fall in to any other category.</td>
<td></td>
</tr>
<tr>
<td>• Text (&quot;text&quot; field) has exceeded its maximum length. (40052): The text that was passed in to translate exceeds the maximum length supported by the corresponding translation service.</td>
<td></td>
</tr>
</tbody>
</table>
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Source language is invalid. (40053): The passed in <code>sourceLanguage</code> parameter contains a language code that is not supported by the corresponding translation service.</td>
</tr>
<tr>
<td></td>
<td>• Target language is invalid. (40054): One or more of the language codes passed in the <code>targetLanguages</code> parameter is not supported by the corresponding translation service.</td>
</tr>
<tr>
<td></td>
<td>• Request is not authorized because credentials are missing or invalid (40055): The credentials configured for the translation service in Connections &amp; Credentials are not valid. For information on connections and credentials, see Dynamic translation overview.</td>
</tr>
<tr>
<td></td>
<td>• Text cannot be translated to target languages. (40056): The specified translation service is not able to translate the passed in text into the specified target languages.</td>
</tr>
</tbody>
</table>

This example shows code in a server-side script that translates a list of text strings into French and Italian using the Microsoft translation service.

```javascript
try {
    gs.info(JSON.stringify(sn_dt_api.DynamicTranslation.getTranslations(["Translate first text using platform from server", "Translate second text using platform from server"], {
        "targetLanguages": ["fr", "it"],
        "additionalParameters": [{"parameterName": "texttype", "parameterValue": "plain"}],
        "translator": "Microsoft"
    }));
} catch (error) {
    gs.error(error.message);
}
```

Response:
This example shows a server script that returns a Partial status when one of the two passed in text strings is invalid.

```javascript
try {
  gs.info(JSON.stringify(sn_dt_api.DynamicTranslation.getTranslations(["Translate first text using platform from server", ""], {
    "targetLanguages": ["fr", "it"],
  }));
}
```
This example shows a server script that throws an error when an invalid translation service is passed in.

```js
try {
  gs.info(JSON.stringify(sn_dt_api.DynamicTranslation.getTranslations(["Translate first text using platform from server", "Translate second text using platform from server"], {
    "targetLanguages": ["fr", "it"],
    "additionalParameters": [{"parameterName": "texttype", "parameterValue": "plain"}],
    "translator": 123
  }));
} catch (error) {
  gs.error(error.message);
}
```
DynamicTranslation - isEnabled(String translator)

Determines whether the various methods in the DynamicTranslation API are enabled for a translation service.

If you pass in a specific translation service, the method checks the method activation for that translation service; otherwise the method checks the default translation service.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>translator</td>
<td>String</td>
<td>Optional. Translation service to use to verify whether the methods are active. Translation services are configured under the Translator Configuration menu. Possible values - not case-sensitive: • Google • Microsoft • IBM • &lt;custom&gt; Note: To use custom translation services you must first configure the translation service in your instance. For details, see Integrate with a translation service provider. Default: Default translation service.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>batchDetection</td>
<td>Flag that indicates whether the getDetectedLanguages() method is enabled.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>Possible values:</td>

<tr>
<td></td>
<td>• true: Enabled</td>
</tr>
<tr>
<td></td>
<td>• false: Disabled</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>batchTranslation</td>
<td>Flag that indicates whether the <code>getTranslations()</code> method is enabled. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Enabled</td>
</tr>
<tr>
<td></td>
<td>• false: Disabled</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>detection</td>
<td>Flag that indicates whether the <code>getDetectedLanguage()</code> method is enabled. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Enabled</td>
</tr>
<tr>
<td></td>
<td>• false: Disabled</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>translation</td>
<td>Flag that indicates whether the <code>getTranslation()</code> method is enabled. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Enabled</td>
</tr>
<tr>
<td></td>
<td>• false: Disabled</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
</tbody>
</table>

Error messages

The following are error messages that the API may return and indications as to their root cause.

• Translator ("translator" field) is invalid. (40003): The passed in `translator` parameter is not a string.

This example shows a server script that checks whether the `DynamicTranslation` methods are active for the Microsoft translator.
try {
    var response = sn_dt_api.DynamicTranslation.isEnabled('Microsoft');
    gs.info(JSON.stringify(response));
} catch(error) {
    gs.info(error.message);
}

Output:

{"detection":true,"batchTranslation":true,"batchDetection":true,"translation":true}

This example shows a server script that throws an error when an invalid translation service is passed in.

try {
    var response = sn_dt_api.DynamicTranslation.isEnabled(123);
    gs.info(JSON.stringify(response));
} catch(error) {
    gs.info(error.message);
}

Output:

{"code":"40003","message":"Translator ("translator" field) is invalid"}

Encoder - Global

Scriptable object used in Predictive Intelligence stores. This object converts input data into vectors of numbers, based on encoder-specific goals and configurations. Encoders can be used independently to run encodings, or can be configured as part of solutions to encode text columns.

The Encoder API requires the Predictive Intelligence plugin (com.glide.platform_ml) and is provided within the sn_ml namespace.

Encoders are text processing objects that are either pre-trained or trained based on the language datasets you provide. You can train encoders that determine how the system interprets and processes text fields. For ML solutions that include text, you can train an encoder to specify how to process text and use the trained encoder in a solution.

Encoders have configuration and versions, and can be trained independently with their own retraining frequency. API-defined encoders are different from UI-defined encoders, because the retraining of UI-defined encoders is controlled by the solutions using them.

The encoder setup-to-training flow is as follows:
1. Create one or more datasets using the `DatasetDefinition` API.
2. Use the `constructor` to create an encoder object.
3. Add the encoder object to the encoder store using the `EncoderStore.add()` method.
4. Train the encoder using the `submitTrainingJob()` method. This creates a version of the object that you can manage using the `EncoderVersion` API.

Once you have trained an encoder, you can use it in a solution object:

- `ClassificationSolution`
- `ClusteringSolution` (required unless using the Levenshtein distance algorithm)
- `RegressionSolution`
- `SimilaritySolution` (required)

**Note:** This API runs with full privileges. To restrict user access, include an access control mechanism in the script.

For usage guidelines, refer to Using ML APIs.

**Encoder - Encoder(Object config)**

Creates an encoder.

To get an encoder for one or more datasets, use this constructor to create a new encoder object with a unique name.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config</td>
<td>Object</td>
<td>JavaScript object containing configuration properties of the encoder.</td>
</tr>
</tbody>
</table>

```json
{
  "algorithmConfig": {Object},
  "datasets": [Array],
  "domainName": "String",
  "label": "String",
  "minRowCount": "String",
  "processingLanguage": "String",
  "stopwords": [Array],
}
```
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config.algorithmConfig</td>
<td>Object</td>
<td>Optional. JavaScript object containing algorithm configuration properties.</td>
</tr>
<tr>
<td>config.algorithmConfig.algo</td>
<td>String</td>
<td>Name of the algorithm for training this encoder. Possible values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• paravec: Paragraph vector word embedding.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• tf-idf: Term Frequency–Inverse Document Frequency (TF-IDF)-based text.</td>
</tr>
<tr>
<td>config.datasets</td>
<td>Array</td>
<td>List of DatasetDefinition object names.</td>
</tr>
<tr>
<td>config.domainName</td>
<td>String</td>
<td>Optional. Domain name associated with this dataset. See Domain separation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>and Predictive Intelligence.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: Current domain, for example, &quot;global&quot;.</td>
</tr>
<tr>
<td>config.label</td>
<td>String</td>
<td>Identifies the prediction task.</td>
</tr>
<tr>
<td>config.minRowCount</td>
<td>String</td>
<td>Optional. Minimum number of records required in the dataset for training.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: 10000</td>
</tr>
<tr>
<td>config.processingLanguage</td>
<td>String</td>
<td>Optional. Processing language in two-letter ISO 639-1 language code format.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config.stopwords</td>
<td>Array</td>
<td>Optional. Preset list of strings that the system automatically generates based on the language property setting. For details, see Create a custom stopwords list. Default: English Stopwords</td>
</tr>
<tr>
<td>config.trainingFrequency</td>
<td>String</td>
<td>The frequency to retrain the model. Possible values: every_30_days, every_60_days, every_90_days, every_120_days, every_180_days, run_once Default: run_once</td>
</tr>
</tbody>
</table>

The following example shows how to create an encoder job and add it to the encoder store.

```javascript
var myPrbData = new sn_ml.DatasetDefinition({
    'tableName': 'problem',
    'fieldNames': ['short_description'],
    'encodedQuery': 'activeANYTHING'
});

var myIncidentData = new sn_ml.DatasetDefinition({
    'tableName': 'incident',
    'fieldNames': ['short_description', 'description'],
    'encodedQuery': 'activeANYTHING'
});

var myEncoder = new sn_ml.Encoder({
```
Encoder - cancelTrainingJob()

Cancels a job for a encoder object that has been submitted for training.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to cancel an existing training job.

```javascript
var myEncoder = sn_ml.EncoderStore.get('ml_sn_global_global_encoder');
myEncoder.cancelTrainingJob();
```

Encoder - getActiveVersion()

Gets the active EncoderVersion object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Active EncoderVersion object.</td>
</tr>
</tbody>
</table>
The following example shows how to get an active Encoder version from the store and return its training status.

```javascript
var mlEncoder = sn_ml.EncoderStore.get('ml_x_snc_global_global_encoder');

gs.print(JSON.stringify(JSON.parse(mlEncoder.getActiveVersion().getStatus()), null, 2));
```

Output:

```javascript
{
  "state": "encoder_complete",
  "percentComplete": "100",
  "hasJobEnded": "true"
}
```

**Encoder - getAllVersions()**

Gets all versions of an encoder.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Existing versions of an encoder object. See also EncoderVersion API.</td>
</tr>
</tbody>
</table>

The following example shows how to get all Encoder version objects and call the getVersionNumber() and getStatus() encoder version methods on them.

```javascript
var mlEncoder = sn_ml.EncoderStore.get('ml_x_snc_global_global_encoder');

var mlEncoderVersions = mlEncoder.getAllVersions();

for (i = 0; i < mlEncoderVersions.length; i++) {
  gs.print("Version "+ mlEncoderVersions[i].getVersionNumber() + " Status: " +
            mlEncoderVersions[i].getStatus() +"\n");
}
```

Output:

```javascript
Version 3 Status: {"state":"encoder_complete","percentComplete":"100","hasJobEnded":"true"}
```
Encoder - getLatestVersion()

Gets the latest version of an encoder.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>EncoderVersion object corresponding to the latest version of an Encoder().</td>
</tr>
</tbody>
</table>

The following example shows how to get the latest version of an encoder and return its training status.

```javascript
var mlEncoder = sn_ml.EncoderStore.get('ml_x_snc_global_global_encoder');

gs.print(JSON.stringify(JSON.parse(mlEncoder.getLatestVersion().getStatus()), null, 2));
```

Output:

```json
{
    "state": "encoder_complete",
    "percentComplete": "100",
    "hasJobEnded": "true"
}
```

### Encoder - getName()

Gets the name of the object to use for interaction with the store.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The following example shows how to update Encoder dataset information and print the name of the object.

```javascript
// Update encoder
var myIncidentData = new sn_ml.DatasetDefinition({
    'tableName': 'incident',
    'fieldNames': ['category', 'short_description', 'priority'],
    'encodedQuery': 'activeANYTHING'
});

var eligibleFields = JSON.parse(myIncidentData.getEligibleFields(encoder));

var myEncoder = new sn_ml.Encoder({
    'label': 'my encoder',
    'datasets': [myIncidentData],
    'inputFieldNames': eligibleFields['eligibleInputFieldNames'],
    'predictedFieldName': 'category'
});

// update encoder
sn_ml.EncoderStore.update('ml_x_snc_global_global_my_definition_4', myEncoder);

// print encoder name
gs.print('Encoder Name: ' + myEncoder.getName());
```

Output:

```
Encoder Name: ml_x_snc_global_global_my_definition_4
```

**Encoder - getProperties()**

Gets solution object properties.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Object</td>
<td>Contents of the Dataset and Encoder() object details in the EncoderStore.</td>
<td></td>
</tr>
</tbody>
</table>

```json
{
  "algorithmConfig": {Object},
  "datasetsProperties": [Array],
  "domainName": "String",
  "label": "String",
  "name": "String",
  "processingLanguage": "String",
  "scope": "String",
  "stopwords": [Array],
  "trainingFrequency": "String"
}
```

- `<Object>.algorithmConfig.algorithm`
  - Name of the algorithm for training this encoder.
  - Possible values:
    - `paravec`: Paragraph vector word embedding.
    - `tf-idf`: Term Frequency–Inverse Document Frequency (TF-IDF)-based text.
  - Data type: String.

- `<Object>.algorithmConfig` Optional. JavaScript object containing
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>algorithm configuration properties.</td>
</tr>
<tr>
<td></td>
<td>`{&quot;algorithmConfig&quot;: {</td>

Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>every_30_days</td>
<td></td>
</tr>
<tr>
<td>every_60_days</td>
<td></td>
</tr>
<tr>
<td>every_90_days</td>
<td></td>
</tr>
<tr>
<td>every_120_days</td>
<td></td>
</tr>
<tr>
<td>every_180_days</td>
<td></td>
</tr>
<tr>
<td>run_once</td>
<td></td>
</tr>
</tbody>
</table>

Default: run_once

Data type: String.

The following example gets properties of an encoder object in the store.

```javascript
var myEncoder = sn_ml.EncoderStore.get('ml_sn_global_global_encoder');

gs.print(JSON.stringify(JSON.parse(myEncoder.getProperties()), null, 2));
```

Output:

```json
*** Script: {
    "datasetsProperties": [
        {
            "tableName": "incident",
            "fieldNames": [
                "assignment_group",
                "short_description",
                "description"
            ],
            "encodedQuery": "activeANYTHING"
        }
    ],
    "domainName": "global",
    "label": "my encoder definition",
    "name": "ml_x_snc_global_global_my_encoder_definition",
    "processingLanguage": "en",
    "scope": "global",
    "stopwords": [
        "Default English Stopwords"
    ],
```
Encoder - getVersion(String version)

Gets an encoder by provided version number.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>String</td>
<td>Existing version number of an encoder.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Specified version of the Encoder() object on which you can call EncoderVersion API methods.</td>
</tr>
</tbody>
</table>

The following example shows how to get the training status of an encoder by version number.

```javascript
var mlEncoder = sn_ml.EncoderStore.get('ml_x_snc_global_global_encoder');

gs.print(JSON.stringify(JSON.parse(mlEncoder.getVersion('1').getStatus()), null, 2));
```

Output:

```javascript
{
  "state": "encoder_complete",
  "percentComplete": "100",
  "hasJobEnded": "true"
}
```

Encoder - setActiveVersion(String version)

Activates a specified version of an encoder in the store.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>String</td>
<td>Name of the Encoder() object version to activate.</td>
</tr>
</tbody>
</table>

© 2021 ServiceNow, Inc. All rights reserved.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Activating this version deactivates any other version.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to activate an encoder version in the store.

```javascript
sn_ml.Encoder.setActiveVersion("ml_incident_categorization");
```

**Encoder - submitTrainingJob()**

Submits a training job.

ℹ️ **Note:** Before running this method, you must first add an encoder to the store using the `EncoderStore - add()` method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>EncoderVersion object corresponding to the Encoder being trained.</td>
</tr>
</tbody>
</table>

The following example shows how to create a dataset, apply it to an encoder, add it to a store, and submit the training job.

```javascript
// Create a dataset
var myData = new sn_ml.DatasetDefinition({
  'tableName' : 'incident',
  'fieldNames' : ['assignment_group', 'short_description', 'description'],
  'encodedQuery' : 'activeANYTHING'
});
```
// Create an encoder
var myEncoder = new sn_ml.Encoder(
    
    'label': "my encoder definition",
    'datasets' : [myData],
    'predictedFieldNames' : 'assignment_group',
    'inputFieldNames': ['short_description']

);

// Add the encoder to the store to later be able to retrieve it.
var my_unique_name = sn_ml.EncoderStore.add(myEncoder);

// Train the encoder - this is a long running job
var myEncoderVersion = myEncoder.submitTrainingJob();

EncoderStore - Global

Enables storing and retrieving encoders.

The EncoderStore API requires the Predictive Intelligence plugin (com.glide.platform_ml) and is provided within the sn_ml namespace.

EncoderStore - add(Object mlEncoder)

Adds a new encoder object to the store and returns a unique name.

⚠️ Note: Label values do not need to be unique. For example, if you run this method with the same label 10 times, this method adds 10 different uniquely-named objects to the store.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mlEncoder</td>
<td>Encoder</td>
<td>Encoder() object to add to the store.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>System-generated solution name.</td>
</tr>
</tbody>
</table>
The following example shows how to add an encoder to the store. Use `Encoder.submitTrainingJob()` to run the training job after adding it to the store.

```javascript
// Create a dataset
var myData = new sn_ml.DatasetDefinition({
    'tableName': 'incident',
    'fieldNames': ['assignment_group', 'short_description', 'description'],
    'encodedQuery': 'activeANYTHING'
});

// Create a solution
var myEncoder = new sn_ml.Encoder({
    'label': "my encoder definition",
    'datasets': [myData],
    'predictedFieldName': 'assignment_group',
    'inputFieldNames': ['short_description']
});

// Add the encoder to the store to later be able to retrieve it.
var my_unique_name = sn_ml.EncoderStore.add(myEncoder);
```

**EncoderStore - deleteObject(String name)**

Removes a specified encoder object from the store.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the <code>Encoder()</code> object to be deleted.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to delete an encoder from the store.

```javascript
sn_ml.EncoderStore.deleteObject("ml_sn_global_global_encoder");
```
EncoderStore - get(String name)
Gets an encoder object from a store.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of an encoder in a store.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Encoder object. Returns an error if the object does not exist.</td>
</tr>
</tbody>
</table>

The following example shows how to get an encoder object from the store using the get() method and view its training status using the Encoder - getActiveVersion() and EncoderVersion - getStatus() methods.

```javascript
// Get status
var myEncoder = sn_ml.EncoderStore.get('ml_incident_categorization');

gs.print(JSON.stringify(JSON.parse(myEncoder.getActiveVersion().getStatus(), null, 2)));
```

Output:

```
{
    "state":"solution_complete",
    "percentComplete":"100",
    "hasJobEnded":"true"
}
```

EncoderStore - getAllNames(Object options)
Gets the names of all encoder definition records in the store.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Object</td>
<td>Options for restricting results within the specified properties.</td>
</tr>
</tbody>
</table>

```javascript
{
    "label": "String",
    "domainName": "String",
}
```
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options.label</td>
<td>String</td>
<td>Optional. Label of your solution object.</td>
</tr>
<tr>
<td>options.domainName</td>
<td>String</td>
<td>Optional. Name of the domain for your solution object. Refer to Domain separation and Predictive Intelligence.</td>
</tr>
<tr>
<td>options.scope</td>
<td>String</td>
<td>Optional. Name of an application scope for your solution object.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>List of strings representing encoder object names in the store.</td>
</tr>
</tbody>
</table>

In the following example, the `getAllNames()` method returns a list of all names in the store.

```javascript
gs.print(JSON.stringify(JSON.parse(sn_ml.EncoderStore.getAllNames()), null, 2));
```

**Output:**

```javascript
[
  "ml_x_snc_global_global_classification_word_corpus",
  "ml_x_snc_global_global_predictability_estimate",
  "GloVe",
  "ml_x_snc_global_global_encoder",
  "ml_x_snc_global_global_predictability_estimate_1"
]
```

In the following example, the `getAllNames()` method returns only names associated with values set in the `options` parameter.

```javascript
var options = {
  'label' : 'my encoder definition',
  'domainName' : 'global',
  'scope' : 'global'
};
```
Output:

```
[
  "ml_x_snc_global_global_my_encoder_definition"
]
```

**EncoderStore - update(String name, Object mlEncoder)**

Updates an encoder object in a store.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the encoder to update.</td>
</tr>
<tr>
<td>mlEncoder</td>
<td>Encoder</td>
<td>Encoder() object properties to update.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to update an encoder object in the store.

```javascript
var encoderUpdate = new sn_ml.Encoder({
  'label': 'my encoder definition',
  'dataset': myData,
  'predictedFieldName': 'assignment_group',
  'inputFieldNames': ['short_description']
});

sn_ml.EncoderStore.update('ml_sn_global_global_incident_service', encoderUpdate);
```

**EncoderVersion - Global**

Scriptable object used in Predictive Intelligence stores.

The EncoderVersion API requires the Predictive Intelligence plugin (com.glide.platform_ml) and is provided within the sn_ml namespace.

This API is used for working with encoder versions based on Encoder API objects in the Encoder store.
The system activates the most recent version of the encoder when it completes training, and only allows one version to be active at a time. However, you can activate any previously trained version you want to use to make predictions.

Methods in this API are accessible using the following Encoder methods:

- `getActiveVersion()`
- `getAllVersions()`
- `getLatestVersion()`
- `getVersion()`

**EncoderVersion - getProperties()**

Gets encoder object properties and version number.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Contents of the Dataset and Encoder details. Results vary by object property setup.</td>
</tr>
</tbody>
</table>

```
{
    // Object
    "algorithmConfig": {Object},
    "datasetsProperties": [Array],
    "domainName": "String",
    "isActive": "String",
    "label": "String",
    "name": "String",
    "predictedFieldName": "String",
    "processingLanguage": "String",
    "scope": "String",
    "stopwords": [Array],
    "trainingFrequency": "String",
    "versionNumber": "Number"
}
```

## Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| `{algorithmConfig: {  
  "algorithm": "String"  
}}` | Data type: Object. |

**algorithmConfig**

Name of the algorithm for training this encoder.

Possible values:

- **paravec**: Paragraph vector word embedding.
- **tf-idf**: Term Frequency–Inverse Document Frequency (TF-IDF)-based text.

Data type: String.

### <Object>.datasetsProperties

List of `DatasetDefinition()` properties associated with the encoder.

```json
{
  "encodedQuery": "String",
  "fieldDetails": [Array],
  "fieldNames": [Array],
  "tableName": "String"
}
```

Data type: Array.

**tableName**

Name of the table for the dataset. For example, "tableName" : "Incident".

Data type: String.

**fieldNames**

List of field names from the specified table as strings. For example, "fieldNames" : ["short_description", "priority"].

Data type: Array.

**fieldDetails**

List of JavaScript objects that specify field properties.
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>}</td>
<td>Data type: Array.</td>
</tr>
</tbody>
</table>

`<Object>.datasetsProperties.fieldDetails.field@type`<br>Field of the type object that information to restrict this dataset to.<br>Data type: String.<br>

`<Object>.datasetsProperties.fieldDetails.<object>.type`<br>Machine-learning field type.<br>Data type: String.<br>

`<Object>.datasetsProperties.encodedQuery`<br>Encoded query string in standard Glide format. See Encoded query strings.<br>Data type: String.<br>

`<Object>.domainName`<br>Domain name associated with this dataset. See Domain separation and Predictive Intelligence.<br>Data type: String.<br>

`<Object>.isActive`<br>Flag that indicates whether this version is active. Valid values:<br>• true: Version is active.<br>• false: Version is not active.<br>Data type: String.<br>

`<Object>.label`<br>Identifies the prediction task.<br>{<br>  "label": "my first prediction"
}<br>Data type: String.<br>

`<Object>.name`<br>System-assigned name.<br>Data type: String.<br>

`<Object>.predictedFieldName`<br>Identifies a field to be trained for predictability.<br>Data type: String.
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Object&gt;.processingLanguage</td>
<td>Processing language in two-letter ISO 639-1 language code format.</td>
</tr>
<tr>
<td></td>
<td>Data type: String.</td>
</tr>
<tr>
<td>&lt;Object&gt;.scope</td>
<td>Object scope. Currently the only valid value is <code>global</code>.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.stopwords</td>
<td>Optional. Preset list of strings that the system automatically generates based on the <code>language</code> property setting. For details, see <a href="#">Create a custom stopwords list</a>.</td>
</tr>
<tr>
<td></td>
<td>Data type: Array.</td>
</tr>
<tr>
<td>&lt;Object&gt;.trainingFrequency</td>
<td>The frequency to retrain the model.</td>
</tr>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>• every_30_days</td>
</tr>
<tr>
<td></td>
<td>• every_60_days</td>
</tr>
<tr>
<td></td>
<td>• every_90_days</td>
</tr>
<tr>
<td></td>
<td>• every_120_days</td>
</tr>
<tr>
<td></td>
<td>• every_180_days</td>
</tr>
<tr>
<td></td>
<td>• run_once</td>
</tr>
<tr>
<td></td>
<td>Default: run_once</td>
</tr>
<tr>
<td></td>
<td>Data type: String.</td>
</tr>
<tr>
<td>&lt;Object&gt;.versionNumber</td>
<td>Version number of the Encoder object.</td>
</tr>
<tr>
<td></td>
<td>Data type: String.</td>
</tr>
</tbody>
</table>

The following example gets properties of the active object version in the store.

```javascript
// Get properties
var mlEncoder = sn_ml.EncoderStore.get('ml_incident_categorization');

gs.print(JSON.stringify(JSON.parse(mlEncoder.getActiveVersion().getProperties()), null, 2));
```

Output:
EncoderVersion - getSentenceVectors(Array input)

Returns vectors for each input sentence.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>Array</td>
<td>Array of strings as sentences from which to receive vectors.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Array of sentence vectors.</td>
</tr>
</tbody>
</table>

The following example shows how to return a vector for a single sentence.

```javascript
var myEncoderName = 'GloVe';

var myEncoder = sn_ml.EncoderStore.get(myEncoderName);
```
```javascript
var input = "I like to code.";

var vectors = myEncoder.getActiveVersion().getSentenceVectors(input);

gs.print(vectors);
```

Output:

```javascript
*** Script: [-0.16243751347064972, 0.30614474415779114, 0.08489049971103668,

```

**EncoderVersion - getSimilarWords(Array input, Object options)**

Returns words similar to each input word in the descending rank order of similarity.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>Array</td>
<td>Array of words for which to find similar words.</td>
</tr>
<tr>
<td>options</td>
<td>Object</td>
<td>Map to refine results.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{ &quot;topN&quot;:&quot;String&quot; }</td>
</tr>
<tr>
<td>options.topN</td>
<td>String</td>
<td>If provided, returns the top results up to the specified number of words. For example, use &quot;10&quot; to return the top 10 most similar words.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>List of elements containing the similar words for the input word in the corresponding position. These similar words are represented by an array of pairs in the format [word, similarity score].</td>
</tr>
</tbody>
</table>
The following example shows how to get similar words using the GloVe encoder.

```javascript
var myEncoderName = 'GloVe';
var myEncoder = sn_ml.EncoderStore.get(myEncoderName);
var input = ['apple'];
var options = {'topN': '5'};
gs.print(myEncoder.getActiveVersion().getSimilarWords(input, options));
```

Output:

```javascript
*** Script:

[[["iphone", 0.5987], ["macintosh", 0.5836], ["ipod", 0.5761], ["microsoft", 0.5664], ["ipad", 0.5628]]]
```

**EncoderVersion - getStatus(Boolean includeDetails)**

Gets training completion status.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>includeDetails</td>
<td>Boolean</td>
<td>Flag that indicates whether to return status <strong>details</strong>. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Return additional details.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Do not return additional details.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: False</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>JavaScript object containing training status information for an <strong>Encoder</strong> object.</td>
</tr>
</tbody>
</table>

```javascript
{
  "state": "String",
  "percentComplete": "Number as a String",
  "hasJobEnded": "Boolean value as a String",
  "details": {Object}
}
```

<Object>.state

Training completion state. If the training job reaches a terminal state, the job does not leave that state. If the state is terminal, the **hasJobEnded** property is set to **true**.
## Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>• fetching_files_for_training</td>
</tr>
<tr>
<td></td>
<td>• preparing_data</td>
</tr>
<tr>
<td></td>
<td>• retry</td>
</tr>
<tr>
<td></td>
<td>• solution_cancelled <em>(terminal)</em></td>
</tr>
<tr>
<td></td>
<td>• solution_complete <em>(terminal)</em></td>
</tr>
<tr>
<td></td>
<td>• solution_error <em>(terminal)</em></td>
</tr>
<tr>
<td></td>
<td>• solution_incomplete</td>
</tr>
<tr>
<td></td>
<td>• training_request_received</td>
</tr>
<tr>
<td></td>
<td>• training_request_timed_out <em>(terminal)</em></td>
</tr>
<tr>
<td></td>
<td>• training_solution</td>
</tr>
<tr>
<td></td>
<td>• uploading_solution</td>
</tr>
<tr>
<td></td>
<td>• waiting_for_training</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>&lt;Object&gt;.hasJobEnded</td>
<td>Flag that indicates whether training is complete.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Training is complete.</td>
</tr>
<tr>
<td></td>
<td>• false: Training is incomplete.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean value as a String</td>
</tr>
<tr>
<td>&lt;Object&gt;.percentComplete</td>
<td>Number between zero and 100 representing training percent complete.</td>
</tr>
<tr>
<td></td>
<td>If the completion percentage is less than 100, the job might be in a terminal state. For example, if training times out.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number as a String</td>
</tr>
<tr>
<td>&lt;Object&gt;.details</td>
<td>Object containing a list of additional training details.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
</tbody>
</table>

The following example shows a successful result with training complete.
// Get status
var mlEncoder = sn_ml.EncoderStore.get('ml_incident_categorization');

gs.print(JSON.stringify(JSON.parse(mlEncoder.getActiveVersion().getStatus(true), null, 2)));

Output:

{
  "state":"solution_complete",
  "percentComplete":"100",
  "hasJobEnded":"true",
  "details":{"stepLabel":"Encoder Complete"} // This information is only returned if
  getStatus(true);
}

The following example shows an unsuccessful result with training complete.

// Get status
var encoderName = 'ml_x_snc_global_global_encoder';
var mlEncoder = sn_ml.EncoderStore.get(encoderName);
var trainingStatus = mlEncoder.getLatestVersion().getStatus();

gs.print(JSON.stringify(JSON.parse(trainingStatus), null, 2));

Output:

{
  "state":"solution_error",
  "percentComplete":"100",
  "hasJobEnded":"true"
}

EncoderVersion - getVersionNumber()

Gets the version number of a solution object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
The following example shows how to get a version number.

```javascript
// Get version number
var mlEncoder = sn_ml.EncoderStore.get('ml_incident_categorization');

gs.print("Version number:
  "+JSON.stringify(JSON.parse(mlEncoder.getActiveVersion().getVersionNumber()), null, 2));
```

Output:

```
Version number: 1
```

**EncoderVersion - getWordVectors(Array input)**

Returns vectors for each input word.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>Array</td>
<td>List of strings as words from which to receive vectors.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>List of vectors for each word provided.</td>
</tr>
</tbody>
</table>

The following example shows how to get a vector from the word hello.

```javascript
var myEncoderName = 'GloVe';
var myEncoder = sn_ml.EncoderStore.get(myEncoderName);
var input = ["hello"];

gs.print(myEncoder.getActiveVersion().getWordVectors(input));
```

Output:

```
*** Script: [\[-0.337119996547699,-0.2169100046157837,-0.006636499892920256, -0.41624999954325684,-1.2554999589920044,-0.0284659992903471,-0.7219499945640564, -0.5288699865341187,0.0072085000574588776,0.3199700117111206,0.02942500077188015, -0.013236000202596188,0.4351100027561188,0.2571600079536438,0.3899500072002411,]
```
Event - Global

The Event API provides methods that enable the setting/getting of values within an event.

These events are sent from a MID Server to a ServiceNow instance. Before you are able to successfully send events, the connection between the MID Server and the ServiceNow instance must be defined.

Use the Event API to add/update fields within an event. Use the SNEventSenderProvider API to instantiate an event sender object. Then use the IEventSender API to send the event to a ServiceNow instance.

You must activate the Event Management (com.glideapp.itom.snac) plugin before attempting to access this API. The Event Management plugin requires a separate subscription and must be activated by ServiceNow personnel. This plugin includes demo data and activates related plugins if they are not already active.

For additional information on event management, see Event Management.

Event - Event()

Instantiates an Event constructor.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var event = new Event();
var esource = event.getField("source");
var eseverity = event.getField("severity");
```

Event - getField(String field)

Returns the current value of the passed in event management field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Name of the event management field value to return.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value of the requested event management field.</td>
</tr>
</tbody>
</table>

```javascript
var event = new Event();
var eventSource = event.getField("source");
var eventSeverity = event.getField("severity");
```

**Event - setAdditionalInfo(String additionalInfo)**

Replaces the existing `additional_info` field in the associated event with the passed in JSON string.

ℹ️ **Note:** You can use the `setfield()` method to update a specific field within the `additional_info` field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalInfo</td>
<td>String</td>
<td>JSON String (key/value pairs) to save in the <code>additional_info</code> field.</td>
</tr>
</tbody>
</table>

ℹ️ **Note:** This parameter replaces the existing information. It does not update the existing fields.

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
event.setAdditionalInfo("{"evtComponent":"Microsoft-Windows-WindowsUpdateClient","evtMessage":"Installation Failure: Windows failed. Error 0x80070490"}");
```

**Event - setField(String key, String value)**

Sets the specified field in the associated event.

If the passed in `key` matches a predefined event field, the method updates the corresponding event field. Otherwise, the method adds the `key` parameter to the `additional_info` section of the event before applying the passed in `value`. 
The following are the predefined event fields that you can modify using this method:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>additional_info</td>
<td>Key-value pair to add to the <code>additional_info</code> field of the associated event. If the passed in key already exists, its value is overwritten.</td>
</tr>
<tr>
<td></td>
<td>Maximum length: 4,000 characters</td>
</tr>
<tr>
<td></td>
<td>Associated UI field: Additional information</td>
</tr>
<tr>
<td>ci_identifier</td>
<td>JSON string that uniquely identifies a configuration item. For example, <code>{&quot;name&quot;:&quot;SAP ORA01&quot;,&quot;type&quot;:&quot;Oracle&quot;}</code>.</td>
</tr>
<tr>
<td></td>
<td>Maximum length: 1,000 characters</td>
</tr>
<tr>
<td>cmdb_ci</td>
<td>Sys_id of the Configuration Item [cmdb_ci] record to bind the event to.</td>
</tr>
<tr>
<td></td>
<td>Default: Null</td>
</tr>
<tr>
<td>description</td>
<td>Free-form description of the event.</td>
</tr>
<tr>
<td></td>
<td>Maximum length: 4,000 characters</td>
</tr>
<tr>
<td></td>
<td>Associated UI field: Description</td>
</tr>
<tr>
<td></td>
<td>Default: Null</td>
</tr>
<tr>
<td>event_class</td>
<td>Enterprise Message Service (EMS) that generated the event. For example, &quot;Solarwinds&quot; or &quot;SCOM&quot;.</td>
</tr>
<tr>
<td></td>
<td>Maximum length: 100</td>
</tr>
<tr>
<td></td>
<td>Associated UI field: Source instance</td>
</tr>
<tr>
<td></td>
<td>Default: Null</td>
</tr>
<tr>
<td>message_key</td>
<td>Unique event identifier. To override an existing event severity, use the same <code>message_key</code> value.</td>
</tr>
<tr>
<td></td>
<td>Maximum length: 1024 characters</td>
</tr>
<tr>
<td></td>
<td>Associated UI field: Message key</td>
</tr>
<tr>
<td></td>
<td>Default: Combination of <code>source</code>, <code>node</code>, <code>type</code>, <code>resource</code>, and <code>metric name</code>.</td>
</tr>
<tr>
<td>resolution_state</td>
<td>Event resolution state.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td></td>
<td>• New: Resolution state for the corresponding event is open.</td>
</tr>
<tr>
<td></td>
<td>• Closing: Resolution state for corresponding event is closing/closed.</td>
</tr>
<tr>
<td></td>
<td>Associated UI field: Resolution state</td>
</tr>
<tr>
<td></td>
<td>Default: New</td>
</tr>
<tr>
<td>resource</td>
<td>Node resource to associate with the event. For example, &quot;Disk C:&quot;, &quot;CPI-1&quot;, or the name of a process or service.</td>
</tr>
<tr>
<td></td>
<td>Maximum length: 100 characters</td>
</tr>
<tr>
<td></td>
<td>Associated UI field: Resource</td>
</tr>
<tr>
<td>severity</td>
<td>Event severity.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• 0: Clear - No action is required. An alert is not created from this event. Existing alerts are closed.</td>
</tr>
<tr>
<td></td>
<td>• 1: Ok - An alert is created. The resource is still functional.</td>
</tr>
<tr>
<td></td>
<td>• 2: Warning - Attention is required, even though the resource is still functional.</td>
</tr>
<tr>
<td></td>
<td>• 3: Minor - Partial, non-critical loss of functionality or performance degradation occurred.</td>
</tr>
<tr>
<td></td>
<td>• 4: Major - Major functionality is severely impaired or performance has degraded.</td>
</tr>
<tr>
<td></td>
<td>• 5: Critical - Immediate action is required. The resource is either not functional or critical problems are imminent.</td>
</tr>
<tr>
<td></td>
<td>Associated UI field: Severity</td>
</tr>
<tr>
<td></td>
<td>Default: Null</td>
</tr>
<tr>
<td>source</td>
<td>Instance of the EMS that triggered the event. Typically the connector instance name.</td>
</tr>
<tr>
<td></td>
<td>Maximum length: 200 characters</td>
</tr>
<tr>
<td></td>
<td>Associated UI field: Source</td>
</tr>
<tr>
<td></td>
<td>Default: Null</td>
</tr>
<tr>
<td>time_of_event</td>
<td>UTC time that the event occurred in the source system.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Metric type to which the event is related, such as Disk or CPU. This value is used to identify an event record from which alerts are created. Maximum length: 100 characters Associated UI field: Type Default: Null</td>
</tr>
<tr>
<td></td>
<td>Format: &quot;yyyy-MM-dd HH:mm:ss&quot; Maximum length: 40 characters Associated UI field: Time of event Default: Current date/time</td>
</tr>
</tbody>
</table>

**Note:** You can also use the `setText()` method to update the `description` field and the `setTimeOfEvent()` method to update the event time.

For additional information on events, see *Event Management*.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Name of the key to add or update in the event. For additional information on the predefined event fields, see <em>Event field format for event collection</em>.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Information to store in the associated event field.</td>
</tr>
</tbody>
</table>

**Note:** The `value` string is trimmed before it is stored, whereby multiple spaces are replaced with a single space.

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var event = new Event();
event.setField("source","SAP Solman");
event.setField("severity","3");
```
event.setField("time_of_event", "2019-18-05 13:12:05");
event.setField("type", "SAP object");
event.setField("user", "admin"); // parameter will be added to additional_info section

Event - setText(String text)

Sets the description field of the associated event to the passed in value.

Note: You can also use the Event - setField(String key, String value) method to set the text field in the current event. Unlike the setField() method, this method does not trim the passed in text.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>String</td>
<td>Text to store in the description field of the associated event.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Max length: 4000 characters</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var event = new Event();
event.setText("SAP Solman");

Event - setTimeOfEvent(String timeOfEvent)

Sets the time_of_event field in the associated event to the passed in UTC time value.

Note: You can also use the Event - setField(String key, String value) method to set the time_of_event field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeOfEvent</td>
<td>String</td>
<td>UTC time value to set in the time_of_event field.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Format: &quot;yyyy-MM-dd HH:mm:ss&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Max length: 40 characters</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var event = new Event();
```

**ExpenseAllocation - Global**

The `ExpenseAllocation` API is included with the Cost Management Plugin as a script include record. It is used by various cost management processes and can also be used for generating custom expense allocation records (`fm_expense_allocation`) from scripted expense allocation rules.

**ExpenseAllocation - createAllocation(GlideRecord target, Number amount)**

Creates an expense allocation (`fm_expense_allocation`) record referencing the parameters provided during instantiation and this method.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>target</td>
<td>GlideRecord</td>
<td>GlideRecord target of the allocation, for example a cost center record to allocate an expense to Decimal amount - the amount of the allocation.</td>
</tr>
<tr>
<td>amount</td>
<td>Number</td>
<td>The amount of the allocation.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the expense allocation was successfully created.</td>
</tr>
</tbody>
</table>

```javascript
var allocation = new ExpenseAllocation(expenseGlideRecord, ruleGlideRecord);
allocation.createAllocation(costCenterGlideRecord, 2345.67);
```

**ExpenseAllocation - ExpenseAllocation(GlideRecord expense, GlideRecord rule)**

Called when you create a new `ExpenseAllocation` object.
This is not needed if scripting advanced allocation rules. This object is already available as the `allocation` variable.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expense</td>
<td>GlideRecord</td>
<td>GlideRecord identifying the source of the expense.</td>
</tr>
<tr>
<td>rule</td>
<td>GlideRecord</td>
<td>GlideRecord identifying the rule to use in allocating the expense line.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ExpenseAllocation object</td>
<td>The ExpenseAllocation object just created.</td>
</tr>
</tbody>
</table>

```javascript
var allocation = new ExpenseAllocation(expenseGlideRecord, ruleGlideRecord);
```

### ExpenseLine - Global

The `ExpenseLine` API is included with the Cost Management Plugin as a script include record. It is used by various cost management processes and can also be used for generating expense line (`fm_expense_line`) records from your own server-side scripts.

### ExpenseLine - createExpense()

Creates a new expense line record.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the expense line was successfully created.</td>
</tr>
</tbody>
</table>
//get some random CI to be used as an expense source
var ci = new GlideRecord("cmdb_ci_server");
    ci.query();
    ci.next();

//create expense line
var exp = new ExpenseLine(ci, 234.56, "Test expense line");
    exp.setSummaryType("run_business");
    var success = exp.createExpense();

ExpenseLine - ExpenseLine (GlideRecord source, Number amount, String description)
Constructor for ExpenseLine object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>GlideRecord</td>
<td>GlideRecord identifying the source of the expense</td>
</tr>
<tr>
<td>amount</td>
<td>Number</td>
<td>Decimal number identifying the amount of the expense</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>(Optional) Description of the expense.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ExpenseLine object</td>
<td>The ExpenseLine object just instantiated.</td>
</tr>
</tbody>
</table>

//get some random CI to be used as an expense source
    var ci = new GlideRecord("cmdb_ci_server");
    ci.query();
    ci.next();

//create expense line
    var exp = new ExpenseLine(ci, 234.56, "Test expense line");

ExpenseLine - processCIParents()
Used internally by the createExpense method to process CI relationships when the expense source is a cmdb_ci record.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**ExpenseLine - setCostSource(GlideRecord costSource)**

Identifies the source rate card or distribution cost that was the source of expense line generation.

This is not the source (CI, task) of the expense.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>costSource</td>
<td>GlideRecord</td>
<td>GlideRecord of CI rate card cost, distribution cost, or task rate card. This is generally only used for system-generated expense lines.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**ExpenseLine - setDescription(String description)**

Defines the description of an expense.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>String</td>
<td>Description of expense.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**ExpenseLine - setParent(GlideRecord expense)**

Sets the parent field on the expense line.

This is generally only used by the system when generating indirect expenses such as business service aggregated expenses.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expense</td>
<td>GlideRecord</td>
<td>Parent expense line record.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**ExpenseLine - setRecurring(Boolean recurring)**

Flags the expense as recurring by setting the recurring field to true.

Expense lines are set to false by default so there is no need to call `setRecurring(false)`.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>recurring</td>
<td>Boolean</td>
<td>Set to true to identify expense line as a recurring expense.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
ExpenseLine - setSummaryType(String summaryType)
Sets a value for the expense line summary_type field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>summaryType</td>
<td>String</td>
<td>Typically you would set this to a value already specified in the expense line summary type field choice list.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
//get some random CI to be used as an expense source
var ci = new GlideRecord("cmdb_ci_server");
ci.query();
ci.next();

//create expense line
var exp = new ExpenseLine(ci, 234.56, "Test expense line");
exp.setSummaryType("run_business");
```

ExtractTermsFromAttachment - Global
Extracts terms from an attachment.

This class is called with the ScriptedExtractor object, SysAttachmentInputStream, the sys_id for the attachment, and the extension for the attachment. The `getTerms()` method is called to extract the terms from the attachment that should be indexed. The `getTerms()` method should just return a string that contains the terms. If you prefer to input a file rather than an input stream, call `extractor.getFile()` to get the File object containing the attachment.

Findings API - Scoped, Global
Provides methods for handling how an Instance Scan check produces findings. This API is included with the Instance Scan (com.glide.instance_scan) plugin. For more information, see Instance Scan.

In Instance Scan, checks run on each record in the scope of a scan on the instance to generate findings. Each finding holds information about an issue record and which check it violated. Findings API methods are used in Instance
Scan checks as part of the `engine` object passed to the user. Add the code to the `Script` field in the check form.

See also:
- Getting started with checks
- Findings

**Findings - increment()**

Increases the count of the current finding.

The finding count starts at zero for each record that a check analyzes in a scan. When called, this method increments the finding count. The count indicates that a finding is to be generated for the current record.

This method can be called multiple times to signify that this finding has multiple occurrences of a check violation in the current record.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to count the number of records with a failed state in a table type check. For more information, see Create a table type check.

```javascript
(function(engine) {
    if (current.getValue("state") == "failed") {
        engine.finding.increment();
    }
})(engine);
```

**Findings - incrementWithNode(Object node)**

If the current finding is from a linter check, this method increments the current finding count and simultaneously passes the linter node object to the finding.
Use this method in the Script field in the Linter Check form. This method saves information about the given node, such as a line number in a current finding’s details column.

See also:
• Advanced linter check scripts
• LinterCheckAstNode API

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node</td>
<td>Object</td>
<td>Node object from the linter check.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to increment linter type nodes in a linter check. For information on using linter check methods, see LinterCheckAstNode API.

```javascript
(function(engine) {
  engine.rootNode.visit(function(node) {
    if (node.getTypeName() === "NAME" &&
        node.getNameIdentifier() === "soughtFunction" &&
        node.getParent().getTypeName() === "CALL") {
      engine.finding.incrementWithNode(node);
    }
  });
})(engine);
```

**Findings - setCurrentSource(GlideRecord source)**

Sets the source of the current finding based on the provided GlideRecord.

Use this method in the **Script** field of a Script Only check. This method is not used for any other checks because they automatically set the source as the current record during the scan. For more information, see Create a script only check.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>GlideRecord</td>
<td>The record to set as the source record for the current finding. This value is added as a reference in the Source field of the Scan Findings [scan_finding] table.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set the current source to an incident record in a script only check. For more information, see Create a script only check.

```javascript
(function(engine) {
    var gr = new GlideRecord('incident');
    gr.get('2f99f330730210100a5310c92bf6a798');
    engine.finding.setCurrentSource(gr);
    engine.finding.increment();
})(engine);
```

### FormInfoHeader - Global

FormInfoHeader allows you to add an HTML message as a form info message. The `addMessage` function is commonly used in record producers. The FormInfoHeader class is available to server-side script.

### FormInfoHeader - addMessage(String message)

Adds an HTML message to the form header, where form info messages are displayed.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>A message that may include HTML tags.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
gs.include("FormInfoHeader");
var fi = new FormInfoHeader();
fi.addMessage('This incident was opened on your behalf<br/>
The IT department will contact you for further information or when the incident is
resolved');
```

FlowAPI - Scoped, Global

Use FlowAPI methods to execute actions, flows, or subflows in server-side scripts using either blocking or non-blocking methods.

Access FlowAPI methods in global and scoped scripts using the sn_fd.FlowAPI object. Create calls to your flows using the Code Snippet action in Flow Designer, or use the methods detailed here to update scripts manually.

**Note:** In domain separated instances, flows, subflows, and actions triggered by this API run in the domain of the user who started the script. For example, if a user in the Acme domain starts a script that triggers a flow, the flow runs in the Acme domain and can only access Acme data, even if the flow runs as the System User.

**Note:** To optimize instance performance, avoid calling these methods from a script for an asynchronous business rule. Instead, create a scheduled job record within the Flow Designer UI.

FlowAPI - cancel(String contextId, String reason)

Cancels a paused or running flow, subflow, or action.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contextId</td>
<td>String</td>
<td>Sys_id of the execution details record for the flow, subflow, or action. Access the execution details by navigating to the Flow Executions tab in Flow Designer, or pass the sys_id of the context record returned by the startFlow(), startSubflow(), or startAction() methods.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example uses the return value of the `startFlow()` method to cancel any long-running flows.

```javascript
(function() {
  var now_GR = new GlideRecord('incident');
  now_GR.addQuery('number', 'INC0000050');
  now_GR.query();
  now_GR.next();

  try {
    var inputs = {};
    inputs['current'] = now_GR; // GlideRecord of table:
    inputs['table_name'] = 'incident';

    // Starts the flow asynchronously.
    var contextId = sn_fd.FlowAPI.startFlow('global.myFlow', inputs);
  }
  catch (ex) {
    var message = ex.getMessage();
    gs.error(message);
  }
})();

// Call the cancel() method using the context Id returned from the startFlow() method
sn_fd.FlowAPI.cancel(contextId, 'Flow took too long to execute.');
```

This example cancels any flows named Test Flow.
var now_GR = new GlideRecord("sys_flow_context");
now_GR.addQuery("name", "Test Flow");
now_GR.query();

while (now_GR.next()) {
    sn_fd.FlowAPI.cancel(now_GR.getUniqueValue(), 'Canceling Test Flows');
}

**FlowAPI - executeAction(String name, Map inputs, Number timeout)**

Runs an action from a server-side script synchronously.

Execute an action from within a business rule, script include, or any other server-side script. Actions run using this method run synchronously, so the method has access to outputs created by the action. Use `startAction` to run an action asynchronously.

ℹ️ **Note:** This API is replaced by `ScriptableFlowRunner`, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the `getRunner()` method in the `FlowAPI` class to return a `ScriptableFlowRunner` object and use the associated methods. Use the `ScriptableFlowRunner` methods if you need to support domain separation.

ℹ️ **Note:** This method runs the action as the user who initiates the session.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The scope and name of the action to be executed, for example <code>global.action_name</code>.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define action inputs. Use the input name, not the input label.</td>
</tr>
<tr>
<td>timeout</td>
<td>Number</td>
<td>Optional. Timeout in milliseconds. This value overrides the 30 second default timeout specified by the <a href="https://service-now.com/">com.glide.hub.flow_api.default_execution_time</a> system property. After the timeout expires, an exception is thrown.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The action outputs.</td>
</tr>
</tbody>
</table>
In this example, the script uses `sn_fd.FlowAPI.executeAction` to execute an action called `actionforpassword2test` in the global scope. A variable called `inputs` contains the inputs for the action. In this case, a name and password. The outputs for the action are stored in the `outputs` variable, which in this case, is an encrypted password object. The code is wrapped in a try/catch statement to capture any errors that might occur when the flow executes.

```javascript
(function() {
    try {
        var inputs = {};
        inputs['name'] = ; // String
        inputs['password2'] = ; // Password (2 Way Encrypted)

        // Execute Synchronously: Run in foreground. Code snippet has access to outputs.
        // var timeout = ; //timeout in ms
        //sn_fd.FlowAPI.executeAction('global.actionforpassword2test', inputs, timeout)
        var outputs = sn_fd.FlowAPI.executeAction('global.actionforpassword2test', inputs);

        // Get Outputs:
        // Note: outputs can only be retrieved when executing synchronously.
        var output = outputs['output']; // Password (2 Way Encrypted)
    } catch (ex) {
        var message = ex.getMessage();
        gs.error(message);
    }
})();
```

**FlowAPI - executeActionQuick(String name, Map inputs, Number timeout)**

Run an action from a server-side script synchronously from the current user session without creating execution details or other related records. Improve performance by eliminating record-keeping overhead. Use this API to increase the speed of high-volume processing, for example multiple executions per second, in a production environment.

⚠️ **Note:** This API is replaced by `ScriptableFlowRunner`, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the `getRunner()` method in the `FlowAPI` class to return a `ScriptableFlowRunner` object and use the associated methods. Use the `ScriptableFlowRunner` methods if you need to support domain separation.
**Note:** Execution details and context records are not created, regardless of Flow Designer settings.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Scope and internal name of the action to execute. For example, <code>global.action_name</code>. Locate the Internal name field in the list of Flow Designer actions.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define action inputs. You can find the available action inputs and required data types under Inputs in the action outline. Use the input name, not the input label. For example, <code>{&quot;table&quot;:&quot;incident&quot;,&quot;sys_id&quot;:&quot;a39d8e3cf0212300964feefe80ff0ed&quot;}</code>.</td>
</tr>
<tr>
<td>timeout</td>
<td>Number</td>
<td>Optional. Timeout in milliseconds. This value overrides the 30 second default timeout specified by the <code>com.glide.hub.flow_api.default_execution_time</code> system property. After the timeout expires, an exception is thrown.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Object containing outputs defined by the action. You can find the outputs for the action under Outputs in the action outline.</td>
</tr>
</tbody>
</table>

```javascript
(function() {
  try {

    var grIncident = new GlideRecord('incident');
    grIncident.get('57af7aec73d423002728660c4cf6a71c');

    var inputs = {};
    inputs['variable'] = grIncident;

    var outputs = sn_fd.FlowAPI.executeActionQuick('global.update_record_test', inputs);

    // Get Outputs:
    // Note: outputs can only be retrieved when executing synchronously.
    var output1 = outputs['output1'];

  } catch (ex) {
  }
})
```
var message = ex.getMessage();
    gs.error(message);
}

FlowAPI - executeDataStreamAction(String name, Map inputs, Number timeout)
Runs a Data Stream action synchronously from a server-side script and returns a ScriptableDataStream object.

For more information about Data Stream actions, see Data Stream actions and pagination.

Note: This API is replaced by ScriptableFlowRunner, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the getRunner() method in the FlowAPI class to return a ScriptableFlowRunner object and use the associated methods. Use the ScriptableFlowRunner methods if you need to support domain separation.

Note: Always wrap data stream logic in a try/catch block to catch errors. Always include a finally statement that ends with the close() method from the ScriptableDataStream class to close the data stream and prevent performance issues.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The scope and name of the Data Stream action to execute. For example, global.data_stream_action_name.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define action inputs. Use the input name, not the input label. If the action does not have any inputs, do not include this parameter.</td>
</tr>
<tr>
<td>timeout</td>
<td>Number</td>
<td>Optional. Amount of time before the action times out. After the timeout expires, an exception is thrown. The timeout only applies to the executeDataStreamAction method, not to methods in the ScriptableDataStream class. Default: 30000, specified by the com.glide.hub.flow_api.default_execution_time system property Unit: Milliseconds</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScriptableDataStream</td>
<td>An object used to iterate through items in the data stream. Use the methods in the ScriptableDataStream class to interact with this object. See ScriptableDataStream API.</td>
</tr>
</tbody>
</table>

This example creates an incident record for each item returned in the data stream.

```javascript
(function() {

  try {

    // Execute Data Stream Action.
    var stream = sn_fd.FlowAPI.executeDataStreamAction('x_my_scope.data_stream_name');

    // Process each item in the data stream
    while (stream.hasNext()) {

      // Get a single item from the data stream.
      var item = stream.next();

      // Use the item.
      var now_GR = new GlideRecord('incident');
      now_GR.setValue('number',item.id);
      now_GR.setValue('short_description',item.name);
      now_GR.insert();

      // By default, this code snippet will terminate after 10 items.
      // Remove or modify this limit after testing your code.
      if (stream.getItemIndex() >= 9) {
        break;
      }
    }
    catch (ex) {
      var message = ex.getMessage();
      gs.error(message);
    }
  }
}
```
FlowAPI - executeFlow(String name, Map inputs, Number timeout)

Runs a flow from a server-side script synchronously.

Execute a flow from within a business rule, script include, or any other server-side script. Flows run using this method run synchronously. Use startFlow to run a flow asynchronously.

⚠️ **Note:** This API is replaced by ScriptableFlowRunner, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the getRunner() method in the FlowAPI class to return a ScriptableFlowRunner object and use the associated methods. Use the ScriptableFlowRunner methods if you need to support domain separation.

⚠️ **Note:** This method runs the flow as the user specified in flow properties.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The scope and name of the flow to be executed, for example global.flow_name.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define trigger inputs. Use the input name, not the input label.</td>
</tr>
<tr>
<td>timeout</td>
<td>Number</td>
<td>Optional. Timeout in milliseconds. This value overrides the 30 second default timeout specified by the com.glide.hub.flow_api.default_execution_time system property. After the timeout expires, an exception is thrown.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Normal operation produces no return value.</td>
</tr>
<tr>
<td>Exception</td>
<td>The API throws an exception when a flow called synchronously pauses. The current execution is in the waiting state. In most cases, the exception is removed when the flow resumes. However, the API cannot resume a flow that has been sent to a MID Server.</td>
</tr>
</tbody>
</table>

This example uses sn_fd.FlowAPI.executeFlow to execute a global flow called test_flow. This flow is normally triggered when a record on the incident table is
updated. Because you are activating the flow from a script, you must provide this information. The code creates an inputs variable that contains the current record, and the table for the record. The code is wrapped in a try/catch statement to capture any errors that might occur when the flow executes.

```javascript
(function() {
    try {
        var inputs = {};
        inputs['current'] = ; // GlideRecord of table:
        inputs['table_name'] = 'incident';
        // Execute Synchronously: Run in foreground.
        // var timeout = ; //timeout in ms
        // sn_fd.FlowAPI.executeFlow('global.test_flow', inputs, timeout)
        sn_fd.FlowAPI.executeFlow('global.test_flow', inputs);
    } catch (ex) {
        var message = ex.getMessage();
        gs.error(message);
    }
})();
```

**FlowAPI - executeFlowQuick(String name, Map inputs, Number timeout)**

Runs a flow, subflow, or action from a server-side script synchronously or asynchronously without creating execution details or other related records. Improves performance by eliminating record-keeping overhead. Use this API to increase the speed of high-volume processing, for example multiple executions per second, in a production environment.

This method runs the flow as the user who initiates the session. Setting the flow to run as the system user, or impersonating a user, is not supported. Flows that include wait conditions, for instance the Wait for a duration of time flow logic or Ask For Approval action, are not supported.

**Note:** This API is replaced by ScriptableFlowRunner, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the getRunner() method in the FlowAPI class to return a ScriptableFlowRunner object and use the associated methods. Use the ScriptableFlowRunner methods if you need to support domain separation.

**Note:** Execution details and context records are not created, regardless of Flow Designer settings.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Scope and internal name of the flow to execute. For example, global.flow_name. Locate the <strong>Internal name</strong> field in the list of Flow Designer flows.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define trigger inputs. You can find the available trigger inputs and required data types in the Trigger section of the flow. Use the input name, not the input label. For example, { 'table': 'incident', 'sys_id': 'a39d8e3cf0212300964feefef80ff0ed' }.</td>
</tr>
<tr>
<td>timeout</td>
<td>Number</td>
<td>Optional. Timeout in milliseconds. This value overrides the 30 second default timeout specified by the com.glide.hub.flow_api.default_execution_time system property. After the timeout expires, an exception is thrown.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```
(function() {

  try {
    var grIncident = new GlideRecord('incident');
    grIncident.get('ed92e8d173d023002723002728660c4cf6a7bc');

    var inputs = {};
    inputs['current'] = grIncident;
    inputs['table_name'] = 'incident';

    sn_fd.FlowAPI.executeFlowQuick('global.test_quick_flow', inputs);

  } catch (ex) {
    var message = ex.getMessage();
    gs.error(message);
  }
})();
```
FlowAPI - executeSubflow(String name, Map inputs, Number timeout)

Runs an subflow from a server-side script synchronously.

Execute a subflow from within a business rule, script include, or any other server-side script. Subflows run using this method run synchronously. Use startSubflow to run an subflow asynchronously.

⚠️ Note: This API is replaced by ScriptableFlowRunner, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the getRunner() method in the FlowAPI class to return a ScriptableFlowRunner object and use the associated methods. Use the ScriptableFlowRunner methods if you need to support domain separation.

⚠️ Note: This method runs the flow as the user specified in flow properties.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The scope and name of the subflow to be executed, for example global.subflow_name.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define subflow inputs. Use the input name, not the input label.</td>
</tr>
<tr>
<td>timeout</td>
<td>Number</td>
<td>Optional. Timeout in milliseconds. This value overrides the 30 second default timeout specified by the com.glide.hub.flow_api.default_execution_time system property. After the timeout expires, an exception is thrown.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Object containing the subflow outputs.</td>
</tr>
<tr>
<td>Exception</td>
<td>The API throws an exception when a flow called synchronously pauses. The current execution is in the waiting state. In most cases, the exception is removed when the flow resumes. However, the API cannot resume a flow that has been sent to a MID Server.</td>
</tr>
</tbody>
</table>

In this example, the script uses sn_fd.FlowAPI.executeSubflow to execute an subflow called subflowTest in the global scope. A variable called inputs contains the inputs for the subflow. In this case, a name and password. The code is wrapped in a try/catch statement to capture any errors that might occur when the flow executes.
(function() {
    try {
        var inputs = {};  
        inputs['name'] = ; // String
        inputs['password2'] = ; // Password (2 Way Encrypted)

        // Execute Synchronously: Run in foreground.
        // var timeout = ; //timeout in ms
        // sn_fd.FlowAPI.executeSubflow('global.subflowTest', inputs, timeout)
        var outputs = sn_fd.FlowAPI.executeSubflow('global.subflowTest', inputs);
    } catch (ex) {
        var message = ex.getMessage();
        gs.error(message);
    }
})() ;

**FlowAPI - executeSubflowQuick(String name, Map inputs, Number timeout)**

Run a subflow from a server-side script synchronously from the current user session without creating execution details or other related records. Improve performance by eliminating record-keeping overhead. Use this API to increase the speed of high-volume processing, for example multiple executions per second, in a production environment.

This method runs the subflow as the user who initiates the session. Setting the subflow to run as the System User, or impersonating a user, is not applied. Subflows that include wait conditions, for instance the Wait for a duration of time flow logic or Ask For Approval action, are not supported.

⚠️ **Note:** This API is replaced by ScriptableFlowRunner, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the getRunner() method in the FlowAPI class to return a ScriptableFlowRunner object and use the associated methods. Use the ScriptableFlowRunner methods if you need to support domain separation.

⚠️ **Note:** Execution details and context records are not created, regardless of Flow Designer settings.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Scope and internal name of the subflow to execute. For example, <code>global.subflow_name</code>. Locate the <strong>Internal name</strong> field in the list of Flow Designer subflows.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define subflow inputs. You can find the available subflow inputs and required data types under Inputs in the subflow. Use the input name, not the input label. For example, <code>{'table': 'incident', 'sys_id': 'a39d8e3cf02130964f3f3f80ff0ed'}</code>.</td>
</tr>
<tr>
<td>timeout</td>
<td>Number</td>
<td>Optional. Timeout in milliseconds. This value overrides the 30 second default timeout specified by the <code>com.glide.hub.flow_api.default_execution_time</code> system property. After the timeout expires, an exception is thrown.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Object containing outputs defined by the subflow. You can find the outputs for the subflow under <strong>Subflow Inputs &amp; Outputs</strong> in the subflow outline.</td>
</tr>
</tbody>
</table>

{(function() {

    try {
        var grIncident = new GlideRecord('incident');
        grIncident.get('57af7aec73d423002728660c4cf6a71c');

        var inputs = {};
        inputs['variable'] = grIncident;

        var outputs = sn_fd.FlowAPI.executeSubflowQuick('global.test_quick_run_subflow', inputs);

        // Get Outputs:
        // Note: outputs can only be retrieved when executing synchronously.
        var output1 = outputs['output1'];

    } catch (ex) {
        var message = ex.getMessage();
        gs.error(message);
    }
})()}

FlowAPI - getOutputs(String contextId)

Returns the outputs of a completed action or subflow.

You can use the return values from either the startAction() or startSubflow() methods as the contextId parameter.

**Note:** This API is replaced by ScriptableFlowRunner, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the getRunner() method in the FlowAPI class to return a ScriptableFlowRunner object and use the associated methods. Use the ScriptableFlowRunner methods if you need to support domain separation.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contextId</td>
<td>String</td>
<td>The sys_id of the action or subflow whose outputs you want to get.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Object containing the action or subflow outputs.</td>
</tr>
</tbody>
</table>

This example starts a global subflow called test_subflow, waits for the flow to finish, and then gets its output values. Normally, a single script does not both run a flow and then get its output values. Since a flow may not complete before the getOutputs() call, this example uses a wait time. Typically, either another script or Flow Designer would have already run the flow. The code is wrapped in a try/catch statement to capture any errors that might occur when the flow executes.

```javascript
(function() {
    try {
        // Gather inputs to call flow
        var inputs = {};
        inputs['ah_task'] = myTaskRecord; // GlideRecord of table: task
        inputs['ah_comment'] = 'Test Comment'; // String
```
// Call flow
var contextId = sn_fd.FlowAPI.startSubflow('global.test_subflow', inputs);

// Wait for the flow to finish running

// Get flow outputs
var outputs = sn_fd.FlowAPI.getOutputs(contextId);
var output1 = outputs['output1'];
return output1;

} catch (ex) {
    var message = ex.getMessage();
    gs.error(message);
}
})

FlowAPI - hasApprovals(String scopedFlowName)
Checks if a flow within a give scope contains any Ask for Approval actions.

The hasApprovals() method determines if a flow within a given scope contains any Ask for Approval actions. This method also checks if any Ask for Approval actions within the flow are nested under If flow logic blocks. For more information, see Ask for Approval actions.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scopedFlowName</td>
<td>String</td>
<td>Scope and internal name of the flow to execute. For example, global.flow_name. Locate the Internal name field in the list of Flow Designer flows.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Returns one of the following string values:</td>
</tr>
<tr>
<td></td>
<td>• ALWAYS: The flow contains an Ask for Approval action that isn’t nested within a conditional If flow logic block.</td>
</tr>
<tr>
<td></td>
<td>• CONDITIONALLY: The flow contains an Ask for Approval action that is nested within a conditional If flow logic block.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• NO: The flow doesn't contain any Ask for Approval actions.</td>
<td></td>
</tr>
<tr>
<td>• UNKNOWN: There was a compiler error, and the system can't determine whether the flow contains any Ask for Approval actions.</td>
<td></td>
</tr>
</tbody>
</table>

The following example checks if the `example_flow` flow within the `global` scope contains any Ask for Approval actions and logs the result.

```javascript
(function() {
  try {
    var result = sn_fd.FlowAPI.hasApprovals('global.example_flow');
    gs.log('Result: ' + result);
  }

  catch (ex) {
    var message = ex.getMessage();
    gs.error(message);
  }
})();
```

**FlowAPI - setEncryptedOutput(String password)**

Builds password2 values inside a script step.

Identify an encrypted password2 value returned from a GlideRecord, enabling the system to display the value as a masked password rather than an encrypted string.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>password</td>
<td>String</td>
<td>Encrypted password2 value.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Encrypted password2 value, recognised by the engine as a password value.</td>
</tr>
</tbody>
</table>

This example returns value of a password2 field from a user record and stores it in a variable. This variable is passed into the setEncryptedOutput method, which is called using `sn_fd.GlideActionUtil.setEncryptedOutput`. The instance recognises the returned value as a password.

```javascript
{function execute(inputs, outputs) {
  // ...code...
  var now_GR = new GlideRecord('sys_user');
  now_GR.addQuery('first_name', 'Abel');
  now_GR.query();
  now_GR.next();
  var pwVal = now_GR.getValue('pw2');
  outputs['usedSetEncrypted'] = sn_fd.GlideActionUtil.setEncryptedOutput(pwVal);
  outputs['justSetDirectly'] = pwVal;
})(inputs, outputs);
```

**FlowAPI - startAction(String name, Map inputs)**

Runs an action from a server-side script asynchronously.

Execute an action from within a business rule, script include, or any other server-side script. Actions run using this method run asynchronously, so scripts using this method do not have access to any outputs created by the action. Use `executeAction` to run an action synchronously and access the outputs it generates.

ℹ️ **Note:** This API is replaced by `ScriptableFlowRunner`, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the `getRunner()` method in the `FlowAPI` class to return a `ScriptableFlowRunner` object and use the associated methods. Use the `ScriptableFlowRunner` methods if you need to support domain separation.

ℹ️ **Note:** This method runs the action as the user who initiates the session.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The scope and name of the action to be executed, for example <code>global.action_name</code>.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define action inputs. Use the input name, not the input label.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys Id of the context record for the action. Access the context record by navigating to the Flow Executions tab in Flow Designer, selecting a flow execution, and clicking <strong>Open Context Record</strong>.</td>
</tr>
</tbody>
</table>

This example uses `sn_fd.FlowAPI.startAction` to execute an action called `add_comment` in the `sn_itsm_spoke` scope. The inputs object contains a target record and a comment to add to that record. The code is wrapped in a try/catch statement to capture any errors that might occur when the flow executes.

```javascript
(function() {
    try {
        var inputs = {};
        inputs['ah_task'] = myTaskRecord; // GlideRecord of table: task
        inputs['ah_comment'] = 'Test Comment'; // String

        var contextId = sn_fd.FlowAPI.startAction('sn_itsm_spoke.add_comment', inputs);
    } catch (ex) {
        var message = ex.getMessage();
        gs.error(message);
    }
})();
```

#### FlowAPI - startActionQuick(String name, Map inputs)

Runs an action from a server-side script asynchronously without creating execution details or other related records. Improve performance by eliminating record-keeping overhead. Use this API to increase the speed of high-volume processing, for example multiple executions per second, in a production environment.
Note: This API is replaced by ScriptableFlowRunner, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the getRunner() method in the FlowAPI class to return a ScriptableFlowRunner object and use the associated methods. Use the ScriptableFlowRunner methods if you need to support domain separation.

Note: Execution details and context records are not created, regardless of Flow Designer settings.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Scope and internal name of the action to execute. For example, global.action_name. Locate the Internal name field in the list of Flow Designer actions.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define action inputs. You can find the available action inputs and required data types under Inputs in the action outline. Use the input name, not the input label. For example, {'table':'incident','sys_id':'a39d8e3cf0212300964feefe80ff0ed'}.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```
(function() {

try {
   var grIncident = new GlideRecord('incident');
   grIncident.get('57af7aec73d423002728660c4cf6a71c');

   var inputs = {};
   inputs['variable'] = grIncident;

   sn_fd.FlowAPI.startActionQuick('global.update_record_test', inputs);

} catch (ex) {
   var message = ex.getMessage();
   gs.error(message);
}
```
FlowAPI - startFlow(String name, Map inputs)
Runs a flow from a server-side script.

Execute a flow from within a business rule, script include, or any other server-side script. Flows executed with this method run asynchronously.

**Note:** This API is replaced by ScriptableFlowRunner, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the getRunner() method in the FlowAPI class to return a ScriptableFlowRunner object and use the associated methods. Use the ScriptableFlowRunner methods if you need to support domain separation.

**Note:** This method runs the flow as the user specified in flow properties.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The scope and name of the flow to be executed, for example global.flow_name.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define trigger inputs. Use the input name, not the input label.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys Id of the context record for the flow. Access the context record by navigating to the Flow Executions tab in Flow Designer, selecting a flow execution, and clicking <strong>Open Context Record</strong>.</td>
</tr>
</tbody>
</table>

This example uses sn_fd.FlowAPI.startFlow to execute a global flow called test_flow. The code creates an inputs variable that contains inputs required by the flow. In this case, the current record and the table for the record. The code is wrapped in a try/catch statement to capture any errors that might occur when the flow executes.

```javascript
(function() {
    var now_GR = new GlideRecord('incident');
    now_GR.addQuery('number', 'INC0009009');
```

```javascript
now_GR.query();
now_GR.next();

try {
    var inputs = {};
    inputs['current'] = now_GR; // GlideRecord of table: Incident
    inputs['table_name'] = 'incident';

    var contextId = sn_fd.FlowAPI.startFlow('global.test_flow', inputs);
    }
    catch (ex) {
        var message = ex.getMessage();
        gs.error(message);
    }
})();
```

**FlowAPI - startFlowQuick(String name, Map inputs)**

Runs a flow from a server-side script asynchronously without creating execution details or other related records. Improve performance by eliminating record-keeping overhead. Use this API to increase the speed of high-volume processing, for example multiple executions per second, in a production environment.

This method runs the flow as the System User. Setting the flow to run as the user who initiates the session, or impersonating a user, is not applied. Flows that include wait conditions, for instance the Wait for a duration of time flow logic or Ask For Approval action, are not supported.

ℹ️ **Note:** This API is replaced by `ScriptableFlowRunner`, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the `getRunner()` method in the `FlowAPI` class to return a `ScriptableFlowRunner` object and use the associated methods. Use the `ScriptableFlowRunner` methods if you need to support domain separation.

ℹ️ **Note:** Execution details and context records are not created, regardless of Flow Designer settings.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Scope and internal name of the flow to execute. For example, <code>global.flow_name</code>. Locate the <strong>Internal name</strong> field in the list of Flow Designer flows.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define trigger inputs. You can find the available trigger inputs and required data types in the Trigger section of the flow. Use the input name, not the input label. For example,</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
(function() {
    try {
        var grIncident = new GlideRecord('incident');
        grIncident.get('ed92e8d173d023002728660c4cf6a7bc');

        var inputs = {};
        inputs['current'] = grIncident;
        inputs['table_name'] = 'incident';

        sn_fd.FlowAPI.startFlowQuick('global.test_quick_flow', inputs);
    } catch (ex) {
        var message = ex.getMessage();
        gs.error(message);
    }
})();
```

**FlowAPI - startSubflow(String name, Map input)**

Runs a subflow from a server-side script.

Execute a subflow from within a business rule, script include, or any other server-side script. Subflows run using this method run asynchronously.
that include this method do not have access to outputs created by the flow. Use `executeSubflow` to run a subflow synchronously and access the outputs it generates.

**Note:** This API is replaced by `ScriptableFlowRunner`, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the `getRunner()` method in the `FlowAPI` class to return a `ScriptableFlowRunner` object and use the associated methods. Use the `ScriptableFlowRunner` methods if you need to support domain separation.

**Note:** This method runs the flow as the user specified in flow properties.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The scope and name of the subflow to be executed, for example <code>global.subflow_name</code>.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define subflow inputs. Use the input name, not the input label.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys Id of the context record for the subflow. Access the context record by navigating to the Flow Executions tab in Flow Designer, selecting a flow execution, and clicking <strong>Open Context Record</strong>.</td>
</tr>
</tbody>
</table>

This example uses `sn_fd.FlowAPI.startSubflow` to execute a global flow called `test_subflow`. The code is wrapped in a try/catch statement to capture any errors that might occur when the flow executes.

```javascript
(function() {
    try {
        var inputs = {};
        inputs['ah_task'] = myTaskRecord; // GlideRecord of table: task
        inputs['ah_comment'] = 'Test Comment'; // String

        var contextId = sn_fd.FlowAPI.startSubflow('global.test_subflow', inputs);
    }
    catch (ex) {
        var message = ex.getMessage();
        gs.error(message);
    }

```

FlowAPI - startSubflowQuick(String name, Map inputs)

Runs a subflow from a server-side script asynchronously without creating execution details or other related records. Improve performance by eliminating record-keeping overhead. Use this API to increase the speed of high-volume processing, for example multiple executions per second, in a production environment.

This method runs the subflow as the System User. Setting the subflow to run as the user who initiates the session, or impersonating a user, is not applied. Subflows that include wait conditions, for instance the Wait for a duration of time flow logic or Ask For Approval action, are not supported.

⚠️ **Note:** This API is replaced by ScriptableFlowRunner, which deprecates the existing methods used to build objects and execute Flow Designer flows and actions. Use the getRunner() method in the FlowAPI class to return a ScriptableFlowRunner object and use the associated methods. Use the ScriptableFlowRunner methods if you need to support domain separation.

⚠️ **Note:** Execution details and context records are not created, regardless of Flow Designer settings.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Scope and internal name of the subflow to execute. For example, <code>global.subflow_name</code>. Locate the <strong>Internal name</strong> field in the list of Flow Designer subflows.</td>
</tr>
<tr>
<td>inputs</td>
<td>Map</td>
<td>Name-value pairs that define subflow inputs. You can find the available subflow inputs and required data types under Inputs in the subflow. Use the input name, not the input label. For example, <code>{'table': 'incident', 'sys_id': 'a239d8e3cf0212300964feeeefe0ff0ed'}</code>.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
(function() {

try {

    var grIncident = new GlideRecord('incident');
    grIncident.get('57af7aec73d423002728660c4cf6a71c');

    var inputs = {};
    inputs['variable'] = grIncident;

    sn_fd.FlowAPI.startSubflowQuick('global.test_quick_run_subflow', inputs);

} catch (ex) {
    var message = ex.getMessage();
    gs.error(message);
}
})();

FlowAPI - getRunner()

Returns a ScriptableFlowRunner builder object for a flow or action that you want to run.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ScriptableFlowRunner</td>
<td>Builder object used to run a Flow Designer action, flow, or subflow.</td>
</tr>
</tbody>
</table>

This example runs a flow synchronously.

(function() {
    try {

        var inputs = {};

...
inputs['sys_id'] = '57af7aec73d423002728660c4cf6a71c'; // Pass the record’s sys_id in as input.

var result = sn_fd.FlowAPI.getRunner() // Create a ScriptableFlowRunner builder object.
    .action('global.markapproved') // Run the global scope action named markapproved.
    .inForeground()
    .inDomain('TOP/ACME') // Run the action from the TOP/ACME domain.
    .withInputs(inputs)
    .run(); // Run the action and return a FlowRunnerResult object.

var contextId = result.getContextId(); // Retrieve the context ID from the result
var dateRun = result.getDate();
var domainUsed = result.getDomainId(); // Retrieve the Domain ID from the result.
var flowName = result.getFlowObjectName();
var flowObjectType = result.getFlowObjectType();

var outputs = result.getOutputs(); // Retrieve any outputs from the action execution.
var newApprovalStatus = outputs['approval']; // Echo back the approval status for verification.

} catch (ex) {
    var message = ex.getMessage();
    gs.error(message);
}

());

---

**FlowScriptAPI - Scoped**

A FlowScriptAPI object allows you to access Flow Designer context details from script steps and inline scripts.

You cannot instantiate objects of this type. Objects of this type are created automatically and are accessible only in script steps and inline scripts.

**FlowScriptAPI - getContextID()**

Returns the context ID of the running flow.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The sys_id of the running flow.</td>
</tr>
</tbody>
</table>

This example assumes you have created a flow containing a Log action. This inline script generates the content of the Log message.

```javascript
var contextId = FlowScriptAPI.getContextID();
return contextId;
```

Output:

4cead85c4da0010598d0c7c6bf73554

Flow - Scoped

Runs activated Flow Designer flows.

This API is deprecated and replaced by the FlowAPI - Scoped, Global and ScriptableFlowRunner - Scoped APIs.

The Flow API can only be used in server scripts.

Use the `sn_fd` namespace to access the Flow API.

Before interacting with a flow using the Flow API, you must first create and activate the flow in the Flow Designer interface. Because the Flow API only interacts with pre-built flows, there is no constructor for the class.

⚠️ Note: To optimize instance performance, avoid calling these methods from a script for an asynchronous business rule. Instead, create a scheduled job record within the Flow Designer UI.

 Scoped Flow - startAsync(String scopeName.flowName, Map flowInputs)

Ignores the trigger and runs an activated flow asynchronously.

Asynchronous calls are non-blocking, allowing the client to execute other code in the script without having to wait for the flow to complete.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scopeName.flowName</td>
<td>String</td>
<td>The application scope for the flow and the internal name of the flow to run. If scopeName is not included, the scope of the user currently logged in is used. Retrieve the internal name of the flow using the <strong>Internal name</strong> column on the Flow Designer landing page.</td>
</tr>
<tr>
<td>flowInputs</td>
<td>Map</td>
<td>Name-value pairs in <code>&lt;String, Object&gt;</code> format that define record-based flow inputs. To call a flow with a record-based trigger, use the format:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>var flowInputs = {};&lt;br&gt;flowInputs['current'] = glideRecord;&lt;br&gt;flowInputs['table_name'] = glideRecord.getTableName();</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The GlideRecord object must be named 'current'. To call a flow with a Service Catalog trigger, use the format:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>var flowInputs = {};&lt;br&gt;flowInputs['request_item'] = glideRecord;&lt;br&gt;flowInputs['table_name'] = glideRecord.getTableName();</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The GlideRecord object must be named 'request_item'.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>PlanResponse object containing the following properties:&lt;br&gt;• contextId: sys_id of the execution details record for the executed flow. Access the execution details by navigating to the Flow Executions tab in Flow Designer and filtering by sys_id.</td>
</tr>
<tr>
<td></td>
<td>An exception occurs when the flow:</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Does not exist within the specified application scope, or the flow or scope name has been misspelled.</td>
<td></td>
</tr>
<tr>
<td>• Is not activated.</td>
<td></td>
</tr>
<tr>
<td>• Exceeds the recursion limit set by the <code>com.glide.hub.flow_engine.indirect_recursion_limit</code> system property. The default value is three.</td>
<td></td>
</tr>
</tbody>
</table>

//Example 1: Run a flow with a record-based trigger
(function startFlowAsync() {
  try {
    // You MUST fetch the GlideRecord that will be passed to the flow
    var glideRecordInput = new GlideRecord('sys_user');
    glideRecordInput.get('62826bf03710200044e0bfc8bcbe5df1');

    var flowInputs = {};
    flowInputs['current'] = glideRecordInput;
    flowInputs['table_name'] = glideRecordInput.getTableName();

    var result = sn_fd.Flow.startAsync('global.recordtriggeredflow', flowInputs);

    //The Sys ID of a flow execution (contextId)
    var contextId = result.contextId;
  }
  catch (ex) {
    var message = ex.getMessage();
    gs.error(message);
  }
})();

//Example 2: Run a flow with a schedule-based trigger
(function startFlowAsync() {
  try {
    var result = sn_fd.Flow.startAsync('global.scheduletriggeredflow');

    //The Sys ID of a flow execution (contextId)
    var contextId = result.contextId;
  } catch (ex) {
    var message = ex.getMessage();
    gs.error(message);
  }
})();
try {
  // You MUST fetch the GlideRecord that will be passed to the flow
  var glideRecordInput = new GlideRecord('sc_req_item');
  glideRecordInput.get(aeed229047801200e0ef563dbb9a71c2);

  var flowInputs = {};
  flowInputs['request_item'] = glideRecordInput;
  flowInputs['table_name'] = glideRecordInput.getTableName();

  var result = sn_fd.Flow.startAsync('global.catalogtriggeredflow', flowInputs);

  //The Sys ID of a flow execution (contextId)
  var contextId = result.contextId;
} catch (ex) {
  var message = ex.getMessage();
  gs.error(message);
}

//Example 4: Run a flow with a MetricBase trigger
(function startMetricBaseFlowAsync() {
  try {

    var oilLevelTriggerRecord = new GlideRecord('oil_levels');
    oilLevelTriggerRecord.get('a4b36222bc72113007b237f48cb97635f');

    var metricTriggerDefinition = new GlideRecord('sys_metric_trigger_definition');
    metricTriggerDefinition.get('21f2eae7c72113007b237f48cb976352');

    var event_time = oilLevelTriggerRecord.getValue('sys_created_on');

    //...
var level = 4;

var metricBaseFlowInputs = {};  
//The record that triggered the metric event
metricBaseFlowInputs['current'] = oilLevelTriggerRecord;
//The MetricBase Trigger Definition record
metricBaseFlowInputs['metric'] = metricTriggerDefinition;
//The time that the 'record' reached a specific metric event level and triggered this flow
metricBaseFlowInputs['event_time'] = event_time;
//The target event level to reach in order for a metric flow to trigger
metricBaseFlowInputs['level'] = level;

var result = sn_fd.Flow.startAsync('global.metricbasedtriggeredflow', metricBaseFlowInputs);

//The Sys ID of a flow execution (contextId)
var contextId = result.contextId;

} catch (ex) {
  var message = ex.getMessage();
  gs.error(message);
}

})();

**g_service_catalog - Client**

The **g_service_catalog** API enables you to access data in a multi-row variable set (MRVS) when a model is open.

This API is available in all environments, such as, Service Portal, Now Platform, Workspace, and Now® Mobile.

**g_service_catalog - getValue(String variableName)**

Returns the value of the specified field on the catalog item form when used in a client script on multi-row variable sets (MRVS).

Use this method when an MRVS modal is open for editing or creating and you want to modify data within the MRVS based on the value of a field on the parent catalog item form. For example, when you need to modify the contents of the cells within an MRVS based on a check box on the parent form. You can also use this method to access the data of other MRVS elements within the same parent form.
Note: This method can only be called from the parent object, such as

```
g_service_catlog.parent.getValue();
```

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
</tr>
<tr>
<td>variableName</td>
<td>String</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Array of objects, with each object containing the name-value pairs of the requested variable.</td>
</tr>
<tr>
<td></td>
<td>For example: [&quot;city&quot;: &quot;San Diego&quot;, &quot;country&quot;: &quot;USA&quot;],</td>
</tr>
<tr>
<td></td>
<td>{&quot;city&quot;: &quot;New Delhi&quot;, &quot;country&quot;: &quot;India&quot;}, {&quot;city&quot;: &quot;Melbourne&quot;, &quot;country&quot;: &quot;Australia&quot;}]</td>
</tr>
</tbody>
</table>

In this example, a catalog item for blocking multiple IP addresses on a firewall has a variable `address_type` with two choices - IPv4 and IPv6. The MRVS has two variables (`ipv4_address` and `ipv6_address`) for the respective address types. If the Address type field on the parent form is set to IPv4, the field IPv6 address is hidden on the MRVS.

```
function onLoad() {
    if (g_service_catalog.parent.getValue("address_type") == "ipv4") {
        g_form.setValue("ipv4_address", "XX.XX.XX.XX");
        g_form.setVisible("ipv6_address", "false");
    }
}
```

**GenericUPSAlarmsReconciler - Global**
Concrete reconciler for generic UPS alarms.
Use this API for SNMP-related discovery.

**GenericUPSAlarmsReconciler - getReconciliationField()**
Returns the reconciliation field.
### GenericUPSAlarmsReconciler - getReconciliationKey()

Returns the reconciliation key.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The reconciliation field</td>
</tr>
</tbody>
</table>

### GenericUPSAlarmsReconciler - hasChanged()

Determines if the generic UPS Bypass information has changed.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the information has changed; otherwise, false.</td>
</tr>
</tbody>
</table>
GenericUPSAlarmsReconciler - readDatabaseFields()

Reads the database fields.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GenericUPSAlarmsReconciler - readDiscovered()

Reads the discovered information.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GenericUPSAlarmsReconciler - setDatabaseFields()

Sets the database fields.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GenericUPSBypassReconciler - Global**

Concrete reconciler for generic UPS bypasses.

Use this API for SNMP-related discovery.

**GenericUPSBypassReconciler - getReconciliationField()**

Returns the reconciliation field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The reconciliation field</td>
</tr>
</tbody>
</table>

**GenericUPSBypassReconciler - getReconciliationKey()**

Returns the reconciliation key.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The reconciliation key</td>
</tr>
</tbody>
</table>
**GenericUPSBypassReconciler - hasChanged()**

Determines if the generic UPS Bypass information has changed.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the information has changed; otherwise, false.</td>
</tr>
</tbody>
</table>

**GenericUPSBypassReconciler - readDatabaseFields()**

Reads the database fields.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GenericUPSBypassReconciler - readDiscovered()**

Reads the discovered information.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td>---</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>void</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**GenericUPSReconciler - setDatabaseFields()**

Sets the database fields.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GenericUPSInputsReconciler - Global**

Concrete reconciler for generic UPS inputs.

Use this API for SNMP-related discovery.

**GenericUPSInputsReconciler - getReconciliationField()**

Returns the reconciliation field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The reconciliation field</td>
</tr>
</tbody>
</table>
GenericUPSInputsReconciler - getReconciliationKey()

Returns the reconciliation key.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The reconciliation key</td>
</tr>
</tbody>
</table>

GenericUPSInputsReconciler - hasChanged()

Determines if the generic UPS Bypass information has changed.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the information has changed; otherwise, false.</td>
</tr>
</tbody>
</table>

GenericUPSInputsReconciler - readDatabaseFields()

Reads the database fields.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### GenericUPSInputsReconciler - readDiscovered()
Reads the discovered information.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### GenericUPSInputsReconciler - setDatabaseFields()
Sets the database fields.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### GenericUPSOutputsReconciler - Global
Concrete reconciler for generic UPS outputs.
Use this API for SNMP-related discovery.
**GenericUPSOutputsReconciler - getReconciliationField()**

Returns the reconciliation field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The reconciliation field</td>
</tr>
</tbody>
</table>

**GenericUPSOutputsReconciler - getReconciliationKey()**

Returns the reconciliation key.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GenericUPSOutputsReconciler - hasChanged()**

Determines if the generic UPS bypass information has changed.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the information has changed; otherwise, false.</td>
</tr>
</tbody>
</table>

**GenericUPSOutputsReconciler - readDatabaseFields()**

Reads the database fields.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GenericUPSOutputsReconciler - readDiscovered()**

Reads the discovered information.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GenericUPSOutputsReconciler - setDatabaseFields()**

Sets the database fields.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GeniusResultAnswer - Scoped**

The `GeniusResultAnswer` API provides methods for creating an answer object in a Genius Result configuration. Answers created with this API define search requests or key-value pair maps that can populate Genius Result answer cards.

You can populate the answer object with query details retrieved from the context of the Genius Result configuration using the `GeniusResultContext` API.

The `GeniusResultAnswer` API methods you must invoke to create the answer object vary by Genius Result answer type:

- For the **Search** answer type, you must invoke the `setTable()` method and either the `setSearchPhrase()` method or the `addSearchPhrases()` method. All other methods are optional except for `addDataMap()`, which is not relevant for this use case.

- For the **Script** answer type, you must invoke the `addDataMap()` method. No other methods are relevant for this use case.

Use this API in Genius Result server-side scripts with the `sn ais` namespace identifier. For more information on scripting logic for Genius Results, see Create a new Genius Result configuration.

**GeniusResultAnswer – addDataMap(Object map)**

Adds a set of arbitrary key-value pair fields to a Genius Result **Script** answer. You can utilize any public Now Platform API to generate these fields.

ℹ️ **Note:** When constructing logic for a Genius Result with the **Script** answer type, you must invoke this method. If you do not invoke this method, the Genius Result answer script fails.

You can add multiple field maps to a single Genius Result answer by invoking this method more than once. Each field map populates a separate Genius Result answer card.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>map</td>
<td>Object</td>
<td>Defines an arbitrary set of key-value pair fields for addition to the Genius Result Script answer. All field values must be Strings.</td>
</tr>
</tbody>
</table>

```javascript
{
  "fieldName1": String,
  "fieldName2": String
}
```

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether invocation of the method succeeded. Valid values: • true: Invocation of the method succeeded. • false: Invocation of the method failed.</td>
</tr>
</tbody>
</table>

This Genius Result Script answer logic adds custom title and URL key-value pair fields to the answer object for display on a Genius Result answer card.

```javascript
function process(context) {
    var answer = new sn_ais.GeniusResultAnswer();

    var customFieldMap = {
        "title": "My custom Genius Result answer",
        "url": "https://example.com/myGeniusResultLink"
    }

    answer.addDataMap(customFieldMap);

    return answer;
}
```

**GeniusResultAnswer – addSearchPhrases(Array searchPhrases)**

Adds terms to the search query defined for a Genius Result Search answer.
**Note:** When constructing logic for a Genius Result with the **Search** answer type, you must invoke the `setTable()` method and either this method or the `setSearchPhrase()` method. If you do not invoke both of the required methods, the Genius Result answer search query fails.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>searchPhraseArray</code></td>
<td>Array</td>
<td>Array of arbitrary Strings to add as terms for the search query made by the Genius Result <strong>Search</strong> answer. Search treats these terms as if separated by the OR operator. Example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><img src="image" alt="Example" /></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether invocation of the method succeeded. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Invocation of the method succeeded.</td>
</tr>
<tr>
<td></td>
<td>• false: Invocation of the method failed.</td>
</tr>
</tbody>
</table>

This Genius Result **Search** answer logic function constructs a search query for records on the User `[sys_user]` table that contain the terms Beth or Anglin.

```javascript
function process(context) {
  var answer = new sn_ais.GeniusResultAnswer();

  answer.setTable('sys_user');
  answer.addSearchPhrases(['Beth', 'Anglin']);

  return answer;
}
```
GeniusResultAnswer – setEncodedQuery(String query)
Sets and encodes the search query for a Genius Result `Search` answer.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>String</td>
<td>Query to use for the search issued by the Genius Result <code>Search</code> answer.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether invocation of the method succeeded.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Invocation of the method succeeded.</td>
</tr>
<tr>
<td></td>
<td>• false: Invocation of the method failed.</td>
</tr>
</tbody>
</table>

This Genius Result `Search` answer logic constructs an encoded search query against the User `[sys_user]` table. The final query joins together multiple subqueries generated from entities detected in the user's original search query.

```javascript
function process(context) {
  var answer = new sn_ais.GeniusResultAnswer();

  answer.setTable('sys_user');
  answer.setSearchLimit(2);
  answer.spellCheck(false);
  var queries = [];
  var matchingSegments;

  var predictionResult = context.getPredictionResult();
  if (predictionResult && predictionResult.length == 1) {
    var detail = predictionResult[0];
    if (detail['result'] && detail['result']['entities']) {
      var entities = detail['result']['entities'];
      for (var i = 0; i < entities.length; i++) {
        if (entities[i]['name'].endsWith('personName')) {
          matchingSegments = entities[i]['matchingSegments'];
          for (var j = 0; j < matchingSegments.length; j++) {
            answer.addSearchPhrases([matchingSegments[j]['value']]);
          }
        } else if (entities[i]['name'].endsWith('cityLocation')) {
        }
      }
    }
  }
}
```
matchingSegments = entities[i]['matchingSegments'];
if (matchingSegments && matchingSegments.length > 0)
    queries.push('location.nameLIKE' + matchingSegments[0]['value']);
} else if (entities[i]['name'].endsWith('departmentName')) {
    matchingSegments = entities[i]['matchingSegments'];
    if (matchingSegments && matchingSegments.length > 0)
        queries.push('department.nameLIKE' + matchingSegments[0]['value']);
} else if (entities[i]['name'].endsWith('jobTitle')) {
    matchingSegments = entities[i]['matchingSegments'];
    if (matchingSegments && matchingSegments.length > 0)
        queries.push('titleLIKE' + matchingSegments[0]['value']);
    }
}
}
}

if (queries.length > 0)
    answer.setEncodedQuery(queries.join('^^'));

return answer;

GeniusResultAnswer – setSearchLimit(Number searchLimit)

Limits the maximum number of search results returned for a Genius Result Search answer. By default, the search query returns up to three results.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>searchLimit</td>
<td>Number</td>
<td>Positive integer value for the maximum number of search results to return for a Genius Result Search answer. Values above 3 have no effect. Default: 3</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether invocation of the method succeeded. Valid values:</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• true: Invocation of the method succeeded.</td>
</tr>
<tr>
<td></td>
<td>• false: Invocation of the method failed.</td>
</tr>
</tbody>
</table>

This Genius Result **Search** answer logic function searches for records from the Catalog Item [sc_cat_item] table that contain the term laptop and returns a maximum of two results.

```javascript
function process(context) {
  var answer = new sn_ais.GeniusResultAnswer();

  answer.setTable('sc_cat_item');
  answer.setSearchPhrase('laptop');
  answer.setSearchLimit(2);

  return answer;
}
```

**GeniusResultAnswer – setSearchPhrase(String searchPhrase)**

Specifies terms for the search query defined for a Genius Result **Search** answer.

**Note:** When constructing logic for a Genius Result with the **Search** answer type, you must invoke the setTable() method and either this method or the addSearchPhrases() method. If you do not invoke both of the required methods, the Genius Result answer search query fails.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>searchPhraseString</td>
<td>String</td>
<td>Terms to use for the search query made by the Genius Result <strong>Search</strong> answer. If you want to retain the original search query terms submitted by the user, set this parameter to the String value returned by the GeniusResultContext.getOriginalSearchPhrase() method.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether invocation of the method succeeded.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Invocation of the method succeeded.</td>
</tr>
<tr>
<td></td>
<td>• false: Invocation of the method failed.</td>
</tr>
</tbody>
</table>

This Genius Result **Search** answer logic function constructs a search query for records from the User [sys_user] table that contain the term Anglin.

```javascript
function process(context) {
    var answer = new sn_ais.GeniusResultAnswer();

    answer.setTable('sys_user');
    answer.setSearchPhrase('Anglin');

    return answer;
}
```

**GeniusResultAnswer – setTable(String table)**

Limits the search query defined for a Genius Result **Search** answer to a specific table. The query only returns search results from the specified table as Genius Result answer cards.

**Note:** When constructing logic for a Genius Result with the **Search** answer type, you must invoke this method and either the `setSearchPhrase()` method or the `addSearchPhrases()` method. If you do not invoke both of the required methods, the Genius Result answer search query fails.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>Now Platform table name. Only indexed records on this table are included in results for the Genius Result <strong>Search</strong> answer.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether invocation of the method succeeded.</td>
</tr>
</tbody>
</table>

Valid values:

• true: Invocation of the method succeeded.
• false: Invocation of the method failed.

This Genius Result **Search** answer logic function constructs a search query for records from the User [sys_user] table that contain the term Anglin.

```javascript
function process(context) {
    var answer = new sn_ais.GeniusResultAnswer();
    answer.setTable('sys_user');
    answer.setSearchPhrase('Anglin');
    return answer;
}
```

**GeniusResultAnswer – spellCheck(Boolean spellCheck)**

Specifies whether to perform typo handling auto-correction (spell checking) for a search query defined in a Genius Result **Search** answer.

If you do not invoke this method for a Genius Result **Search** answer, the defined search query inherits the typo handling flag from the search query that activated the Genius Result configuration.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spellCheck</td>
<td>Boolean</td>
<td>Flag that indicates whether to perform typo handling auto-correction for the search query defined in a Genius Result <strong>Search</strong> answer.</td>
</tr>
</tbody>
</table>

Valid values:

• true: Perform typo handling auto-correction for the search query.
• false: Bypass typo handling auto-correction for the search query.
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Default: true</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

This Genius Result `Search` answer logic disables typo handling auto-correction for its search query against the User `sys_user` table.

```javascript
function process(context) {
    var answer = new sn_ais.GeniusResultAnswer();

    answer.setTable('sys_user');
    answer.setSearchLimit(2);
    answer.spellCheck(false);
    var queries = [];
    var matchingSegments;
    var predictionResult = context.getPredictionResult();
    if (predictionResult && predictionResult.length == 1) {
        var detail = predictionResult[0];
        if (detail['result'] && detail['result']['entities']) {
            var entities = detail['result']['entities'];
            for (var i = 0; i < entities.length; i++) {
                if (entities[i]['name'].endsWith('personName')) {
                    matchingSegments = entities[i]['matchingSegments'];
                    for (var j = 0; j < matchingSegments.length; j++)
                        answer.addSearchPhrases([matchingSegments[j]['value']]);
                } else if (entities[i]['name'].endsWith('cityLocation')) {
                    matchingSegments = entities[i]['matchingSegments'];
                    if (matchingSegments && matchingSegments.length > 0)
                        queries.push('location.nameLIKE' + matchingSegments[0]['value']);
                } else if (entities[i]['name'].endsWith('departmentName')) {
                    matchingSegments = entities[i]['matchingSegments'];
                    if (matchingSegments && matchingSegments.length > 0)
                        queries.push('department.nameLIKE' + matchingSegments[0]['value']);
                } else if (entities[i]['name'].endsWith('jobTitle')) {
                    matchingSegments = entities[i]['matchingSegments'];
                    if (matchingSegments && matchingSegments.length > 0)
                        queries.push('titleLIKE' + matchingSegments[0]['value']);
                }
            }
        }
    }
```
if (queries.length > 0)
    answer.setEncodedQuery(queries.join('^'));

return answer;
}

GeniusResultContext - Scoped

The GeniusResultContext API provides methods for retrieving search query information from the context of a Genius Result configuration.

You can use search query details retrieved with this API to populate Genius Result answer objects created with the GeniusResultAnswer API.

Use this API in Genius Result server-side scripts with the sn_ais namespace identifier. For more information on scripting logic for Genius Results, see Create a new Genius Result configuration.

GeniusResultContext – getOriginalSearchPhrase()

Retrieves the user's original search query terms from the search query. You can use these terms to populate Genius Result answers using GeniusResultAnswer API methods.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Original terms from the search query.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

This Genius Result Search answer logic function gets the search query's original terms and uses them as the query terms for a new snippet search.

```javascript
function process(context) {
    var answer = new sn_ais.GeniusResultAnswer();
}
var searchPhrase = context.getOriginalSearchPhrase();
answer.setSearchPhrase(searchPhrase);
answer.snippetSearch(true);

return answer;
}

GeniusResultContext – getPredictionResult()

Retrieves NLU model prediction results for the search query.

Use this method to retrieve the intent detected for the search query. You can populate Genius Result answers with details from the detected intent using GeniusResultAnswer API methods.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| [Array]| Array of objects in which each object represents an NLU model intent prediction result for the search query.  

Data type: Array

```javascript
[
{
  "intentName": "String",
  "result": {Object},
  "solutionName": "String",
}
]
```

[Array].intentName

Name of the NLU model intent detected in the search query.  

Data type: String

[Array].result

Object representing the NLU model intent prediction result for the search query.  

Data type: Object
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;result&quot;: {</td>
<td></td>
</tr>
<tr>
<td>&quot;application&quot;: {Object},</td>
<td></td>
</tr>
<tr>
<td>&quot;result&quot;: {Object},</td>
<td></td>
</tr>
<tr>
<td>&quot;solutionLabel&quot;: &quot;String&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;solutionName&quot;: &quot;String&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;solutionType&quot;: &quot;String&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;type&quot;: &quot;String&quot;,</td>
<td></td>
</tr>
<tr>
<td>&quot;version&quot;: Number</td>
<td></td>
</tr>
<tr>
<td>]</td>
<td></td>
</tr>
</tbody>
</table>

[Array].result.application

Object containing metadata for the search application that produced the prediction result.

Data type: Object

"application": {
  "language": "String",
  "type": "String"
}

[Array].result.application.language

Language context for the Now Platform application that produced the prediction result.

Data type: String

[Array].result.application.type

Type of the Now Platform application that produced the prediction result.

Data type: String

[Array].result.result

Object including details for the NLU model intent prediction result.

Data type: Object

"result": {
  "entities": [Array],
  "intentName": "String",
  "intents": [Array],
  "nluModelName": "String",
  "score": Number
}

[Array].result.result.entities

Array of objects in which each object represents an NLU model intent entity detected in the search query.
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Data type: Array</strong></td>
</tr>
<tr>
<td></td>
<td>&quot;entities&quot;: [</td>
</tr>

<tr>
<td></td>
<td>&quot;startingPosition&quot;: Number,</td>
</tr>
<tr>
<td></td>
<td>&quot;value&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
</tbody>
</table>

**[Array].result.result.entities.matchingSegments**

Array of objects in which each object represents a matching segment of the detected NLU entity.

**Data type: Array**

```
"matchingSegments": [ |
|   |
|   "directMatch": Boolean |
|   "meta": {Object}, |
|   "value": "String" |
| ] |
```

**[Array].result.result.entities.matchingSegments.directMatch**

Flag that indicates whether the NLU entity matching segment represents an exact match for the entity value.

**[Array].result.result.entities.matchingSegments.meta**

Object containing key-value pair fields representing metadata for the NLU entity matching segment.

**Data type: Object**

```
"meta": { |
|   "augmentedBy": "String", |
|   "colMeta:first_name": "String", |
|   "colMeta:last_name": "String", |
|   "compositionStrategy": "String", |
|   "fieldName": "String", |
|   "searchPreProcessors": "String", |
|   "SUB_PHRASE.penalty": "String", |
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>&quot;tableName&quot;: &quot;String&quot;</td>
</tr>
</tbody>
</table>

[Array].result.result.entities.matchingSegments.value

String value of the NLU entity matching segment.
Data type: String

[Array].result.result.entities.name

Name for the detected NLU entity, in entity:[NLU_model].[intent].[entity_type] format.
Data type: String

[Array].result.result.entities.parts

Array of objects in which each object represents an NLU entity part found in the prediction result.
Data type: Array

"parts": [
  {
    "meta": {Object},
    "value": "String"
  }
]

[Array].result.result.entities.parts.meta

Object containing key-value pair fields representing metadata for the NLU entity part.
Data type: Object

"meta": {
  "augmentedBy": "String",
  "colMeta:name": "String",
  "compositionStrategy": "String",
  "fieldName": "String",
  "searchPreProcessors": "String",
  "SUB_PHRASE.penalty": "String",
  "tableName": "String"
}

[Array].result.result.entities.parts.value

String value of the NLU entity part.
Data type: String

[Array].result.result.entities.score

Numeric score from 0 through 1 indicating confidence for the detected NLU entity.
Data type: Number
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Array].result.result.entities.startingPosition</td>
<td>Numeric index for the character position in the search query at which the detected NLU entity begins. Data type: Number</td>
</tr>
<tr>
<td>[Array].result.result.entities.value</td>
<td>String value of the NLU detected in the search query. Data type: String</td>
</tr>
<tr>
<td>[Array].result.result.intentName</td>
<td>Name of the NLU model intent detected in the search query. Data type: String</td>
</tr>
<tr>
<td>[Array].result.result.intents</td>
<td>Array of objects in which each object represents a nested NLU model intent detected in the search query. Nested intent objects include the same parameter names and data types as the parent NLU model intent object. Data type: Array</td>
</tr>
<tr>
<td>[Array].result.result.nluModelName</td>
<td>Name of the NLU model that produced the prediction result. Data type: String</td>
</tr>
<tr>
<td>[Array].result.result.score</td>
<td>Numeric score from 0 through 1 indicating confidence for the NLU model prediction result. Data type: Number</td>
</tr>
<tr>
<td>[Array].result.solutionLabel</td>
<td>Label for the NLU model that produced the prediction result. Data type: String</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[Array].result.solutionName</td>
<td>Name for the NLU model that produced the prediction result.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>[Array].result.solutionType</td>
<td>Type for the NLU model that produced the prediction result.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>[Array].result.type</td>
<td>Type of the prediction result.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>[Array].result.version</td>
<td>Version of the NLU model that produced the prediction result.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>[Array].solutionName</td>
<td>Name of the NLU model that produced the prediction result.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

This Genius Result Search answer logic function checks whether the search query includes an NLU model prediction result. When it finds a prediction result, it adds the matching segments from all detected catalogItem entities as search terms.

```javascript
function process(context) {
  var answer = new sn_ais.GeniusResultAnswer();

  answer.setTable('sc_cat_item');
  answer.setSearchLimit(2);
  var predictionResult = context.getPredictionResult();
  if (predictionResult && predictionResult.length == 1) {
    var detail = predictionResult[0];
    if (detail['result'] && detail['result']['entities']) {
      var entities = detail['result']['entities'];
      for (var i = 0; i < entities.length; i++) {
        if (entities[i]['name'].endsWith('catalogItem')) {
          var matchingSegments = entities[i]['matchingSegments'];
          for (var j = 0; j < matchingSegments.length; j++)
            answer.addSearchPhrases([matchingSegments[j]['value']]);
        }
      }
    }
  }
}
```

GlideAgentWorkspace (g_aw) - Client

The g_aw API enables a UI Action or client script to open a specified record in an Agent Workspace tab.

There is no constructor for the GlideAgentWorkspace class. Access GlideAgentWorkspace methods using the g_aw global object.

GlideAgentWorkspace - closeRecord()

Closes the currently open record, such as a form, in a subtab within Agent Workspace.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example saves the content of the tab and then closes it.

```javascript
function onClick(g_form) {
  g_form.save().then(function()
    g_aw.closeRecord();
  );
}
```

GlideAgentWorkspace - openRecord(String table, String sysId, Object params)

Opens a specified record, such as a form, in a subtab within Agent Workspace.
**Note:** This method is only available in the Agent Workspace client scripting environment or in a UI action on the workspace client script field.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>Name of the table that contains the record to open.</td>
</tr>
<tr>
<td>sysId</td>
<td>String</td>
<td>Sys ID of the record to open.</td>
</tr>
<tr>
<td>params</td>
<td>Object</td>
<td>Optional. Name/value pairs of the parameters to pass to the record.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>params.readOnlyForm</td>
<td>Boolean</td>
<td>Flag that indicates whether all fields on the opened record are read-only; regardless of the UI policy and ACLs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: All fields are read only.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Fields adhere to the associated UI policy and ACLs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td>params.defaultTab</td>
<td>String</td>
<td>Name of the initial tab to display in the workspace. You can only specify related items or related lists.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If not specified, the details tab appears unless <strong>hideDetails</strong> is set to true.</td>
</tr>
</tbody>
</table>
|                   |          | For more information on the method to use to obtain a related list name, see `getRelatedListNames()`.
| params.hideDetails | Boolean  | Flag that indicates whether to hide the details tab and the UI actions.     |
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>true: Only the form header, all other tabs, and the first available tab appear on the form.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>false: Details tab and UI actions appear on the form.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Default: false</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Open a sys_user record in a subtab.

```
g_aw.openRecord('sys_user', '62826bf03710200044e0bfc8bcbe5df1');
```

Open a record in a subtab where all fields are read-only.

```
g_aw.openRecord('sys_user', '62826bf03710200044e0bfc8bcbe5df1', {readOnlyForm: true});
```

Open a record in a subtab and go directly to the "Groups" related list.

```
g_aw.openRecord('sys_user', '62826bf03710200044e0bfc8bcbe5df1', {defaultTab: "sys_user_grmember.user"});
```

Open a record in a subtab but only show the form header and other tabs.

```
g_aw.openRecord('sys_user', '62826bf03710200044e0bfc8bcbe5df1', {hideDetails: true});
```

**GlideAggregate - Global**

GlideAggregate enables creating database aggregation queries.

The GlideAggregate class is an extension of GlideRecord and provides database aggregation (AVG, COUNT, MIN, MAX, STDDEV, SUM) queries. This functionality can be helpful when creating customized reports or in calculations for calculated fields. The GlideAggregate class works only on number fields.

When you use GlideAggregate on currency or price fields, you are working with the reference currency value. Be sure to convert the aggregate values to the user's session currency for display. Because the conversion rate between
the currency or price value (displayed value) and its reference currency value (aggregation value) might change, the result may not be what the user expects.

Note: When using an on-premise system, the database server time zone must be set to GMT/UTC for this class to work properly.

GlideAggregate - addAggregate(String agg, String name)

Adds an aggregate to a database query.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| agg   | String  | Name of an aggregate to include in a database query. Valid values:  
  • AVG  
  • COUNT  
  • MIN  
  • MAX  
  • STDDEV  
  • SUM  |
| name  | String  | Optional. Name of the field to group the results of the aggregation by. Default: Null |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to add aggregates to a query on the category and software fields in the Incident [incident] table.

```javascript
var incidentGA = new GlideAggregate('incident');

incidentGA.addQuery('category', 'software');

incidentGA.setGroup(false);
```
incidentGA.addAggregate('COUNT', 'sys_mod_count');
incidentGA.addAggregate('SUM', 'sys_mod_count');
incidentGA.addAggregate('AVG', 'sys_mod_count');
incidentGA.addAggregate('MIN', 'sys_mod_count');
incidentGA.addAggregate('MAX', 'sys_mod_count');
incidentGA.addAggregate('STDDEV', 'sys_mod_count');

incidentGA.query();

if (incidentGA.next()) {
    gs.info('COUNT: ' + incidentGA.getAggregate('COUNT', 'sys_mod_count'));
    gs.info('SUM: ' + incidentGA.getAggregate('SUM', 'sys_mod_count'));
    gs.info('AVG: ' + incidentGA.getAggregate('AVG', 'sys_mod_count'));
    gs.info('MIN: ' + incidentGA.getAggregate('MIN', 'sys_mod_count'));
    gs.info('MAX: ' + incidentGA.getAggregate('MAX', 'sys_mod_count'));
    gs.info('STDDEV: ' + incidentGA.getAggregate('STDDEV', 'sys_mod_count'));
}

Output
COUNT: 13
SUM: 273
AVG: 21.0000
MIN: 3
MAX: 95
STDDEV: 32.7694

Scoped equivalent
To use the addAggregate() method in a scoped application, use the corresponding scoped method: Scoped GlideAggregate - addAggregate(String agg, String name).

GlideAggregate - addEncodedQuery(String query)
Adds an encoded query to the other queries that may have been set for this aggregate.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>String</td>
<td>Encoded query string to add to the aggregate.</td>
</tr>
</tbody>
</table>
var agg = new GlideAggregate('incident');
agg.addAggregate('count','category');
agg.orderByAggregate('count', 'category');
agg.orderBy('category');
agg.addQuery('opened_at', '>=', 'javascript:gs.monthsAgoStart(2)');
agg.addQuery('opened_at', '<=', 'javascript:gs.monthsAgoEnd(2)');
agg.query();
while (agg.next()) {
    var category = agg.category;
    var count = agg.getAggregate('count','category');
    var query = agg.getQuery();
    var agg2 = new GlideAggregate('incident');
    agg2.addAggregate('count','category');
    agg2.orderByAggregate('count', 'category');
    agg2.orderBy('category');
    agg2.addQuery('opened_at', '>=', 'javascript:gs.monthsAgoStart(3)');
    agg2.addQuery('opened_at', '<=', 'javascript:gs.monthsAgoEnd(3)');
    agg2.addEncodedQuery(query);
    agg2.query();
    var last = "";
    while (agg2.next()) {
        last = agg2.getAggregate('count','category');
    }
    gs.log(category + ": Last month:" + count + " Previous Month:" + last);
}

Scoped equivalent
To use the `addEncodedQuery()` method in a scoped application, use the corresponding scoped method: **Scoped GlideAggregate** - `addEncodedQuery(String query)`.

**GlideAggregate - addHaving(String name, String operator, String value)**

Adds a "having" element to the aggregate, such as select category, count(*) from incident group by category HAVING count(*) > 5.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Aggregate to filter on. For example, COUNT.</td>
</tr>
<tr>
<td>operator</td>
<td>String</td>
<td>Operator symbol. For example &lt;, &gt;, =, !=.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Value to query on. For example, '5'.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```
var trend = new GlideAggregate('incident');
trend.addTrend ('opened_at','Month');
trend.addAggregate('COUNT');

//addHaving limits the results returned to those in which the aggregate COUNT is greater than 2
trend.addHaving('COUNT', '>', '2');
trend.setGroup(false);
trend.query();
while(trend.next()) {
    gs.print(('Incidents by month ' + trend.getValue('timeref') + ' where count is more than 2 count is: ' + trend.getAggregate('COUNT')));
}
```

Output

- Incidents by month 9/2018 where count is more than 2 count is: 3
- Incidents by month 10/2018 where count is more than 2 count is: 8
- Incidents by month 11/2018 where count is more than 2 count is: 14

**GlideAggregate - addTrend(String fieldName, String timeInterval, Number numUnits)**

Adds a trend for a field.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field for which trending should occur.</td>
</tr>
<tr>
<td>timeInterval</td>
<td>String</td>
<td>Time interval for the trend. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• date</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• dayofweek</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• hour</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• minute</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• quarter</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• value</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• week</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• year</td>
</tr>
<tr>
<td>numUnits</td>
<td>Number</td>
<td>Optional. Only valid when <code>timeInterval = minute</code>. Number of minutes to include in the trend. Default: 1</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var trend = new GlideAggregate('incident');
trend.addTrend ('opened_at','month');
trend.addAggregate('COUNT');
trend.setGroup(false);
trend.query();
while(trend.next()) {
    gs.print(trend.getValue('timeref') + ': ' + trend.getAggregate('COUNT'));
}
```

### Output

9/2018: 3  
10/2018: 8  
11/2018: 14
Scoped equivalent

To use the `addTrend(String fieldName, String timeInterval)` method in a scoped application, use the corresponding scoped method: `Scoped GlideAggregate - addTrend(String fieldName, String timeInterval, Number numUnits)`. 

**GlideAggregate - getAggregate(String agg, String name)**

Gets the value of an aggregate from the current record.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg</td>
<td>String</td>
<td>Type of the aggregate. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• AVG</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• COUNT</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MIN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MAX</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• STDDEV</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SUM</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field to get the aggregate from.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value of the aggregation. If the values being aggregated are FX Currency values, the returned value is in the format <code>&lt;currency_code;currency_value&gt;</code>, such as: USD;134.980000.</td>
</tr>
</tbody>
</table>

**Note:** If the specified field contains FX Currency values of mixed currency types, the method is not able to aggregate the values and returns a semicolon (;).

This example shows how to obtain the COUNT aggregate.

```javascript
function doMyBusinessRule(assigned_to, number) {
    var agg = new GlideAggregate('incident');
    agg.addQuery('assigned_to', assigned_to);
    // ...
agg.addQuery('category', number);
agg.addAggregate("COUNT");
agg.query();
var answer = 'false';
if (agg.next()) {
    answer = agg.getAggregate("COUNT");
    if (answer > 0)
        answer = 'true';
    else
        answer = 'false';
}
return answer;

This example shows the aggregation of an FX Currency field.

var ga = new GlideAggregate('laptop_tracker');
ga.addAggregate('SUM', 'cost');
ga.groupBy('name');
ga.query();
while (ga.next()) {
    gs.info('Aggregate results ' + ga.getValue('name') + ' => ' + ga.getAggregate('SUM', 'cost'));
}

Output:

*** Script: Aggregate results Apple MacBook Air => USD;1651.784280000000

Scoped equivalent

To use the getAggregate() method in a scoped application, use the corresponding scoped method: Scoped GlideAggregate - getAggregate(String agg, String name).

GlideAggregate - getQuery()

Retrieves the query necessary to return the current aggregate.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The query.</td>
</tr>
</tbody>
</table>

```javascript
var agg = new GlideAggregate('incident');
agg.addAggregate('count', 'category');
agg.orderByAggregate('count', 'category');
agg.orderBy('category');
agg.addQuery('opened_at', '>=', 'javascript:gs.monthsAgoStart(2)');
agg.addQuery('opened_at', '<=', 'javascript:gs.monthsAgoEnd(2)');
agg.query();
while (agg.next()) {
    var category = agg.category;
    var count = agg.getAggregate('count', 'category');
    var query = agg.getQuery();
    var agg2 = new GlideAggregate('incident');
    agg2.addAggregate('count', 'category');
    agg2.orderByAggregate('count', 'category');
    agg2.orderBy('category');
    agg2.addQuery('opened_at', '>=', 'javascript:gs.monthsAgoStart(3)');
    agg2.addQuery('opened_at', '<=', 'javascript:gs.monthsAgoEnd(3)');
    agg2.addEncodedQuery(query);
    agg2.query();
    var last = "";
    while (agg2.next()) {
        last = agg2.getAggregate('count', 'category');
    }
    gs.log(category + "": Last month:" + count + " Previous Month:" + last);
}
```

**GlideAggregate - getTotal(String agg, String name)**

Returns the number of records by summing an aggregate.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg</td>
<td>String</td>
<td>Aggregate</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field to aggregate</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of records.</td>
</tr>
</tbody>
</table>

### GlideAggregate - getValue(String name)

Returns the value of a field.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value of the field.</td>
</tr>
</tbody>
</table>

```javascript
var trend = new GlideAggregate('incident');
trend.addTrend ('opened_at','Month');
trend.addAggregate('COUNT');

//addHaving limits the results returned to those in which the aggregate COUNT is greater than 2
trend.addHaving('COUNT', '>', '2');
trend.setGroup(false);
trend.query();
while(trend.next()) {
    gs.print(('Incidents by month ' + trend.getValue('timeref') + ' where count is more than 2 count is: ' + trend.getAggregate('COUNT')));
}
```
Incidents by month 9/2018 where count is more than 2 count is: 3
Incidents by month 10/2018 where count is more than 2 count is: 8
Incidents by month 11/2018 where count is more than 2 count is: 14

Scoped equivalent
To use the `getValue()` method in a scoped application, use the corresponding scoped method: **Scoped GlideAggregate - getValue(String name).**

**GlideAggregate - groupBy(String name)**
Provides the name of a field to use in grouping the aggregates.

May be called numerous times to set multiple group fields.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var count = new GlideAggregate('incident');
count.addAggregate('MIN', 'sys_mod_count');
count.addAggregate('MAX', 'sys_mod_count');
count.addAggregate('AVG', 'sys_mod_count');
count.groupBy('category');
count.query();
while (count.next()) {
    var min = count.getAggregate('MIN', 'sys_mod_count');
    var max = count.getAggregate('MAX', 'sys_mod_count');
    var avg = count.getAggregate('AVG', 'sys_mod_count');
    var category = count.category.getDisplayValue();
    gs.log(category + ' Update counts: MIN = ' + min + ' MAX = ' + max + ' AVG = ' + avg);
}
```

Scoped equivalent
To use the `groupBy()` method in a scoped application, use the corresponding scoped method: **Scoped GlideAggregate - groupBy(String name).**
**GlideAggregate - orderBy(String name)**

Provides the name of a field that should be used to order the aggregates. The field will also be added to the group-by list.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field used to order the aggregates.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```
var agg = new GlideAggregate('incident');
agg.addAggregate('count','category');
agg.orderByAggregate('count', 'category');
agg.orderBy('category');
agg.addQuery('opened_at', '>=', 'javascript:gs.monthsAgoStart(2)');
agg.addQuery('opened_at', '<=', 'javascript:gs.monthsAgoEnd(2)');
agg.query();
while (agg.next()) {
    var category = agg.category;
    var count = agg.getAggregate('count','category');
    var query = agg.getQuery();
    var agg2 = new GlideAggregate('incident');
    agg2.addAggregate('count','category');
    agg2.orderByAggregate('count', 'category');
    agg2.orderBy('category');
    agg2.addQuery('opened_at', '>=', 'javascript:gs.monthsAgoStart(3)');
    agg2.addQuery('opened_at', '<=', 'javascript:gs.monthsAgoEnd(3)');
    agg2.addEncodedQuery(query);
    agg2.query();
    var last = "";
    while (agg2.next()) {
        last = agg2.getAggregate('count','category');
    }
    gs.log(category + " : Last month:" + count + " Previous Month:" + last);
}
```
**Scoped equivalent**

To use the `orderBy()` method in a scoped application, use the corresponding scoped method: `Scoped GlideAggregate - orderBy(String name)`.

**GlideAggregate - orderByAggregate(String agg, String name)**

Orders the aggregates based on the specified aggregate and field.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg</td>
<td>String</td>
<td>Type of aggregation, for example SUM, COUNT, MIN, MAX.</td>
</tr>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field to aggregate.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var agg = new GlideAggregate('incident');
agg.addAggregate('count','category');
agg.orderByAggregate('count', 'category');
agg.orderBy('category');
agg.addQuery('opened_at', '>=', 'javascript:gs.monthsAgoStart(2)');
agg.addQuery('opened_at', '<=', 'javascript:gs.monthsAgoEnd(2)');
agg.query();
while (agg.next()) {
  var category = agg.category;
  var count = agg.getAggregate('count','category');
  var query = agg.getQuery();
  var agg2 = new GlideAggregate('incident');
  agg2.addAggregate('count','category');
  agg2.orderByAggregate('count', 'category');
  agg2.orderBy('category');
  agg2.addQuery('opened_at', '>=', 'javascript:gs.monthsAgoStart(3)');
  agg2.addQuery('opened_at', '<=', 'javascript:gs.monthsAgoEnd(3)');
  agg2.addEncodedQuery(query);
  agg2.query();
  var last = "";
  while (agg2.next()) {
    last = agg2.getAggregate('count','category');
  }
}
```
Scoped equivalent

To use the `orderByAggregate()` method in a scoped application, use the corresponding scoped method: `Scoped GlideAggregate - orderByAggregate(String agg, String fieldName)`. 

GlideAggregate - query()

Issues the query and gets the results.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var agg = new GlideAggregate('incident');
agg.addAggregate('count','category');
agg.orderByAggregate('count', 'category');
agg.orderBy('category');
agg.addQuery('opened_at', '>=', 'javascript:gs.monthsAgoStart(2)');
agg.addQuery('opened_at', '<=', 'javascript:gs.monthsAgoEnd(2)');
agg.query();
while (agg.next()) {
    var category = agg.category;
    var count = agg.getAggregate('count','category');
    var query = agg.getQuery();
    var agg2 = new GlideAggregate('incident');
    agg2.addAggregate('count','category');
    agg2.orderByAggregate('count', 'category');
    agg2.orderBy('category');
    agg2.addQuery('opened_at', '>=', 'javascript:gs.monthsAgoStart(3)');
    agg2.addQuery('opened_at', '<=', 'javascript:gs.monthsAgoEnd(3)');
```
agg2.addEncodedQuery(query);
agg2.query();
var last = "";
while (agg2.next()) {
  last = agg2.getAggregate('count', 'category');
}
gs.log(category + " Last month:" + count + " Previous Month:" + last);

Scoped equivalent

To use the `query()` method in a scoped application, use the corresponding scoped method: `Scoped GlideAggregate - query()`.

GlideAggregate - `setGroup(Boolean b)`

Sets whether to group the results.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| b    | Boolean | Flag that indicates whether to group the results. Valid values:  
|      |         | • true: Group the results.  
|      |         | • false: Do not group the results.               |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var ga = new GlideAggregate('incident');
ga.addAggregate('COUNT', 'category');
ga.setGroup(true);

Scoped equivalent

To use the `setGroup()` method in a scoped application, use the corresponding scoped method: `Scoped GlideAggregate - setGroup(Boolean b)`.

GlideAggregate - Scoped

GlideAggregate enables creating database aggregation queries.

The scoped GlideAggregate class is an extension of GlideRecord and provides database aggregation (AVG, COUNT, MIN, MAX, STDDEV, SUM) queries. This functionality can be helpful when creating customized reports or in calculations for calculated fields. The GlideAggregate class works only on number fields.

When you use GlideAggregate on currency or price fields, you are working with the reference currency value. Be sure to convert the aggregate values to the user’s session currency for display. Because the conversion rate between the currency or price value (displayed value) and its reference currency value (aggregation value) might change, the result may not be what the user expects.

Note: When using an on-premise system, the database server time zone must be set to GMT/UTC for this class to work properly.

Scoped GlideAggregate - addAggregate(String agg, String name)

Adds an aggregate to a database query.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| agg   | String| Name of an aggregate to include in a database query. Valid values:  
|       |       | • AVG  
|       |       | • COUNT  
|       |       | • MIN  
|       |       | • MAX  
|       |       | • STDDEV  
|       |       | • SUM  
| name  | String| Optional. Name of the field to group the results of the aggregation by. Default: Null

The following example shows how to add aggregates to a query on the category and software fields in the Incident [incident] table.

```javascript
var incidentGA = new GlideAggregate('incident');

incidentGA.addQuery('category', 'software');

incidentGA.setGroup(false);

incidentGA.addAggregate('COUNT', 'sys_mod_count');
incidentGA.addAggregate('SUM', 'sys_mod_count');
incidentGA.addAggregate('AVG', 'sys_mod_count');
incidentGA.addAggregate('MIN', 'sys_mod_count');
incidentGA.addAggregate('MAX', 'sys_mod_count');
incidentGA.addAggregate('STDDEV', 'sys_mod_count');

incidentGA.query();

if (incidentGA.next()) {
    gs.info('COUNT: ' + incidentGA.getAggregate('COUNT', 'sys_mod_count'));
    gs.info('SUM: ' + incidentGA.getAggregate('SUM', 'sys_mod_count'));
    gs.info('AVG: ' + incidentGA.getAggregate('AVG', 'sys_mod_count'));
    gs.info('MIN: ' + incidentGA.getAggregate('MIN', 'sys_mod_count'));
    gs.info('MAX: ' + incidentGA.getAggregate('MAX', 'sys_mod_count'));
    gs.info('STDDEV: ' + incidentGA.getAggregate('STDDEV', 'sys_mod_count'));
}
```

Output

| COUNT   | 13  |
| SUM     | 273 |
| AVG     | 21.0000 |
| MIN     | 3  |
| MAX     | 95 |
| STDDEV  | 32.7694 |
Scoped GlideAggregate - addEncodedQuery(String query)

Adds an encoded query to the other queries that may have been set for this aggregate.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>String</td>
<td>An encoded query to add to the aggregate.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
//Number of incidents varies depending on the current state
//of the incident table
var count = new GlideAggregate('incident');
count.addEncodedQuery('active=true');
count.addAggregate('COUNT');
count.query();
var incidents = 0;
if (count.next())
    incidents = count.getAggregate('COUNT');
gs.info(incidents);
```

Scoped GlideAggregate - addQuery(String name, String operator, String value)

Adds a query to the aggregate.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The query to add.</td>
</tr>
<tr>
<td>operator</td>
<td>String</td>
<td>The operator for the query.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The list of values to include in the query.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>The query condition.</td>
</tr>
</tbody>
</table>

```javascript
//Number of incidents varies depending on the current state
//of the incident table
var count = new GlideAggregate('incident');
count.addQuery('active', '=''true'');
count.addAggregate('COUNT', 'category');
count.query();
while (count.next()) {
    var category = count.category;
    var categoryCount = count.getAggregate('COUNT', 'category');
    gs.info("There are currently \" + categoryCount + \" incidents with a category of \" +
    category);
}
```

Output:

There are currently 1 incidents with a category of database
There are currently 5 incidents with a category of hardware
There are currently 42 incidents with a category of inquiry
There are currently 4 incidents with a category of network
There are currently 4 incidents with a category of request
There are currently 7 incidents with a category of software

**Scoped GlideAggregate - addNotNullQuery(String fieldName)**

Adds a not null query to the aggregate.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The name of the field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>The scoped query condition.</td>
</tr>
</tbody>
</table>
```javascript
var count = new GlideAggregate('incident');
count.addNotNullQuery('short_description');
count.query();   // Issue the query to the database to get all records
while (count.next()) {
    // add code here to process the aggregate
}
```

**Scoped GlideAggregate - addNullQuery(String fieldName)**

Adds a null query to the aggregate.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The name of the field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>The scoped query condition.</td>
</tr>
</tbody>
</table>

```javascript
var count = new GlideAggregate('incident');
count.addNullQuery('short_description');
count.query();   // Issue the query to the database to get all records
while (count.next()) {
    // add code here to process the aggregate
}
```

**Scoped GlideAggregate - addTrend(String fieldName, String timeInterval, Number numUnits)**

Adds a trend for a specified field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field for which trending should occur.</td>
</tr>
<tr>
<td>timeInterval</td>
<td>String</td>
<td>Time interval for the trend. Valid values:</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• date</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• dayofweek</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• hour</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• minute</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• quarter</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• week</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• year</td>
<td></td>
<td></td>
</tr>
<tr>
<td>numUnits</td>
<td>Number</td>
<td>Optional. Only valid when <code>timeInterval = minute</code>. Number of minutes to include in the trend. Default: 1</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var ga = new GlideAggregate('incident');
ga.addAggregate('COUNT'); // Count all incidents opened each quarter
ga.addTrend('opened_at', 'quarter');
ga.query();
while(ga.next()) {
  gs.info([ga.getValue('timeref'), ga.getAggregate('COUNT')]);
}
```

**Output:**

- 3/2018, 9
- 4/2018, 2
- 1/2019, 38
- 2/2019, 310

---

**Scoped GlideAggregate - getAggregate(String agg, String name)**

Returns the value of an aggregate from the current record.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg</td>
<td>String</td>
<td>The type of the aggregate. For example, SUM or COUNT.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field on which to perform the aggregation.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The value of the aggregation.</td>
</tr>
<tr>
<td></td>
<td>If the values being aggregated are FX Currency values, the returned value</td>
</tr>
<tr>
<td></td>
<td>is in the format <code>&lt;currency_code;curren_value&gt;</code>, such as: USD;134.980000.</td>
</tr>
</tbody>
</table>

ℹ️ **Note:** If the specified field contains FX Currency values of mixed currency types, the method is not able to aggregate the values and returns a semicolon (;).

Shows an aggregation that returns the number of records in the Incident table.

```javascript
var count = new GlideAggregate('incident');
count.addAggregate('COUNT');
count.query();
var incidents = 0;
if (count.next()) {
  incidents = count.getAggregate('COUNT');
}
//Number of incidents varies depending on the current state of the incident table
gs.info('Number of incidents: ' + incidents);
```

**Output:** Number of incidents: 63

Shows the aggregation of an FX Currency field.

```javascript
var ga = new GlideAggregate('laptop_tracker');
ga.addAggregate('SUM', 'cost');
ga.groupBy('name');
ga.query();
while (ga.next()) {
  gs.info('Aggregate results ' + ga.getValue('name') + ' => ' + ga.getAggregate('SUM', 'cost'));
}
```
Output: *** Script: Aggregate results Apple MacBook Air => USD:1651.784280000000
*** Script: Aggregate results Apple MacBook Pro => USD:1651.784280000000
*** Script: Aggregate results Dell XPS => USD:470.852672000000
*** Script: Aggregate results LG =>
*** Script: Aggregate results Samsung Galaxy => USD:225.320000000000
*** Script: Aggregate results Surface3 => USD:2895.560369520000
*** Script: Aggregate results Toshiba => USD:9385.202875800000

Scoped GlideAggregate - getAggregateEncodedQuery()

Gets the query necessary to return the current aggregate.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The encoded query to get the aggregate.</td>
</tr>
</tbody>
</table>

```javascript
var count = new GlideAggregate('incident');
count.addAggregate('MIN', 'sys_mod_count');
count.groupBy('category');
count.query();
while (count.next()) {
    gs.info(count.getAggregateEncodedQuery());
}
```
**Scoped GlideAggregate - getEncodedQuery()**
Retrieves the encoded query.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The encoded query.</td>
</tr>
</tbody>
</table>

```javascript
var count = new GlideAggregate('incident');
count.addAggregate('MIN', 'sys_mod_count');
count.addAggregate('MAX', 'sys_mod_count');
count.addAggregate('AVG', 'sys_mod_count');
count.groupBy('category');
count.query();
gs.info(count.getEncodedQuery());
```

Output:

```javascript
ORDERBYcategory^GROUPBYcategory
```

**Scoped GlideAggregate - getRowCount()**
Retrieves the number of rows in the GlideAggregate object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of rows in the GlideAggregate object.</td>
</tr>
</tbody>
</table>

```javascript
var count = new GlideAggregate('incident');
count.addAggregate('MIN', 'sys_mod_count');
```
```javascript
var count = new GlideAggregate('incident');
count.addAggregate('MIN', 'sys_mod_count');
count.addAggregate('MAX', 'sys_mod_count');
count.addAggregate('AVG', 'sys_mod_count');
count.groupBy('category');
gs.info(count.getRowCount());
while (count.next()) {
    var min = count.getAggregate('MIN', 'sys_mod_count');
    var max = count.getAggregate('MAX', 'sys_mod_count');
    var avg = count.getAggregate('AVG', 'sys_mod_count');
    var category = count.category.getDisplayValue();
    gs.info(category + " Update counts: MIN = " + min + " MAX = " + max + " AVG = " + avg);
}
```

Output:

```plaintext
6
Database Update counts: MIN = 8 MAX = 48 AVG = 28.0000
Hardware Update counts: MIN = 4 MAX = 14 AVG = 6.6250
Inquiry / Help Update counts: MIN = 0 MAX = 34 AVG = 6.5714
Network Update counts: MIN = 3 MAX = 37 AVG = 18.6000
Request Update counts: MIN = 5 MAX = 39 AVG = 13.4000
Software Update counts: MIN = 4 MAX = 98 AVG = 24.0000
```

Scoped GlideAggregate - getTableName()
Retrieves the table name associated with this GlideAggregate object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>none</td>
<td>none</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The table name.</td>
</tr>
</tbody>
</table>

```javascript
var count = new GlideAggregate('incident');
count.addAggregate('MIN', 'sys_mod_count');
count.addAggregate('MAX', 'sys_mod_count');
count.addAggregate('AVG', 'sys_mod_count');
count.groupBy('category');
```
count.query();
gs.info(count.getTableName());

Scoped GlideAggregate - getValue(String name)
Returns the value of the specified field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field within the current table to return.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value of the specified field.</td>
</tr>
</tbody>
</table>

var count = new GlideAggregate('incident');
count.addAggregate('MAX', 'sys_mod_count');
count.groupBy('category');
count.query();
while (count.next()) {
    gs.info(count.getValue('category') + " category had " + count.getAggregate('MAX', 'sys_mod_count') + " updates");
}

Output:
category had 12 updates
hardware category had 15 updates
inquiry category had 36 updates
network category had 37 updates
software category had 95 updates

Scoped GlideAggregate - GlideAggregate(String tableName)
Creates a GlideAggregate object on the specified table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table.</td>
</tr>
</tbody>
</table>
```javascript
var count = new GlideAggregate('incident');

count.addAggregate('MIN', 'sys_mod_count');
count.addAggregate('MAX', 'sys_mod_count');
count.addAggregate('AVG', 'sys_mod_count');
count.groupBy('category');
count.query();

while (count.next()) {
    var min = count.getAggregate('MIN', 'sys_mod_count');
    var max = count.getAggregate('MAX', 'sys_mod_count');
    var avg = count.getAggregate('AVG', 'sys_mod_count');
    var category = count.category.getDisplayValue();
    gs.info(category + " Update counts: MIN = " + min + " MAX = " + max + " AVG = " + avg);
}
```

**Output:**

- **Database Update counts:** MIN = 8 MAX = 48 AVG = 28.0000
- **Hardware Update counts:** MIN = 4 MAX = 14 AVG = 6.6250
- **Inquiry / Help Update counts:** MIN = 0 MAX = 34 AVG = 6.5714
- **Network Update counts:** MIN = 3 MAX = 37 AVG = 18.6000
- **Request Update counts:** MIN = 5 MAX = 39 AVG = 13.4000
- **Software Update counts:** MIN = 4 MAX = 98 AVG = 24.0000
Scoped GlideAggregate - hasNext()

Determines if there are any more records in the GlideAggregate object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if there are more results in the query set.</td>
</tr>
</tbody>
</table>

```javascript
var agg = new GlideAggregate('incident');
agg.addAggregate('AVG', 'sys_mod_count');
agg.groupBy('category');
agg.query();
while (agg.hasNext()) {
    agg.next();
    var avg = agg.getAggregate('AVG', 'sys_mod_count');
    var category = agg.category.getDisplayValue();
    gs.info(category + ': AVG = ' + avg);
}
```

**Output:**

Database: AVG = 32.5000
Hardware: AVG = 12.0000
Inquiry / Help: AVG = 7.6667
Network: AVG = 24.0000
Request: AVG = 16.4000
Software: AVG = 27.0833

Scoped GlideAggregate - next()

Moves to the next record in the GlideAggregate.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if there are more records in the query set; otherwise, false.</td>
</tr>
</tbody>
</table>

```javascript
var count = new GlideAggregate('incident');
count.addAggregate('COUNT');
count.query();
var incidents = 0;
if (count.next()) {
  incidents = count.getAggregate('COUNT');
  gs.info(incidents);
}
```

Scoped GlideAggregate - orderBy(String name)

Orders the aggregates using the value of the specified field. The field will also be added to the group-by list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field to order the aggregates by.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var agg = new GlideAggregate('incident');
agg.addAggregate('count', 'category');
agg.orderBy('category');
agg.query();
while (agg.next()) {
  var category = agg.category;
  var count = agg.getAggregate('count', 'category');
  var agg2 = new GlideAggregate('incident');
  agg2.addAggregate('count', 'category');
  agg2.orderBy('category');
  gs.info(category + " Current number of incidents:" + count);
}
```
Output:

database: Current number of incidents: 2
hardware: Current number of incidents: 8
inquiry: Current number of incidents: 28
network: Current number of incidents: 5
request: Current number of incidents: 5
software: Current number of incidents: 11

**Scoped GlideAggregate - orderByAggregate(String agg, String fieldName)**

Orders the aggregates based on the specified aggregate and field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agg</td>
<td>String</td>
<td>Type of aggregation.</td>
</tr>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field to aggregate.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```plaintext
ga.addAggregate('COUNT', 'category');
ga.orderByAggregate('count', 'category');
ga.query();

while(ga.next()) {
   gs.info('Category ' + ga.category + ' ' + ga.getAggregate('COUNT', 'category'));
}
```

Output:

Category inquiry 18
Category software 11
Category hardware 7
Category network 5
Category request 5
**Scoped GlideAggregate - orderByDesc(String name)**

Sorts the aggregates in descending order based on the specified field. The field will also be added to the group-by list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var agg = new GlideAggregate('incident');
agg.addAggregate('count', 'category');
agg.orderByDesc('category');
agg.query();
while (agg.next()) {
    var category = agg.category;
    var count = agg.getAggregate('count', 'category');
    var agg2 = new GlideAggregate('incident');
    agg2.addAggregate('count', 'category');
    agg2.orderBy('category');
    gs.info(category + " Current number of incidents:" + count);
}
```

**Output:**

```
software: Current number of incidents:11
request: Current number of incidents:5
network: Current number of incidents:5
inquiry: Current number of incidents:28
hardware: Current number of incidents:8
database: Current number of incidents:2
```
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var count = new GlideAggregate('incident');
count.addAggregate('COUNT');
count.query();
var incidents = 0;
if (count.next()) {
    incidents = count.getAggregate('COUNT');
}
gs.info('Number of incidents: ' + incidents);
```

### Scoped GlideAggregate - setGroup(Boolean b)
Sets whether the results are to be grouped.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>Boolean</td>
<td>When true the results are grouped.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var ga = new GlideAggregate('incident');
ga.addAggregate('COUNT', 'category');
ga.setGroup(true);
ga.groupBy("category");
```
ga.query();

while(ga.next()) {
    gs.info('Category ' + ga.category + ' ' + ga.getAggregate('COUNT', 'category'));
}

Output:

Category database 2
Category hardware 7
Category inquiry 18
Category network 5
Category request 5
Category software 11

**GlideApplicationProperty - Scoped, Global**

The *GlideApplicationProperty* API provides the ability to get and set application property values for a specific domain.

Application properties enable service providers to customize application functionality based on the domain. Instead of only having a single system property (System Property [sys_properties] table) that defines the functionality for all domains and users, application properties can be implemented to define functionality for specific domains.

To access this API you must activate the Domain Support - Domain Extensions Installer (com.glide.domain.msp_extensions.installer) plugin.

For additional information on domain-specific application properties, see Domain-separated application properties.

**GlideApplicationProperty - getValue(String name, String domainSysId)**

Returns the value for the specified application property and domain sys_id.

The list of available application properties is located in the Application Properties [sys_application_property] and Application Property Values [sys_application_property_value] tables.

⚠️ **Note:** If the specified domain is a child domain, and there is not an application property for the child domain, the method returns the parent domain application property, if available.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the application property to return.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td></td>
<td>If the application is not global, you must prefix the name of the sys_application_property with the application's scope.</td>
</tr>
<tr>
<td>domainSysId</td>
<td>String</td>
<td>Optional. Sys_id of the domain associated with the application property.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: Session domain</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value of the specified application property for the specified domain. If domainSysId is not passed in the call, then returns the session domain. If the specified application property doesn't exist, returns the same-name system property value. If the user does not have access rights to the specified domain, throws an exception and no value is returned.</td>
</tr>
</tbody>
</table>

This example shows how to create a new application property and override its value for ACME and Cisco domains.

```javascript
var MY_APP_PROP_NAME = 'my-app-prop';
var ACME_DOMAIN_ID = 'c90d4b084a362312013398f051272c0d';
var CISCO_DOMAIN_ID = 'c90f91924a362312001bdefae0f35d68';

// create a new app_config entry:
var now_GR = new GlideRecord('sys_application_property');
now_GR.name = MY_APP_PROP_NAME;
now_GR.default_value = 'my-app-prop-default_value';
now_GR.insert();

// Override the value for ACME domain, catch exception if user can't access the specified domain
try {
    GlideApplicationProperty.setValue(MY_APP_PROP_NAME, 'prop-value-ACME', ACME_DOMAIN_ID);
    gs.info('Value for ACME domain: ' + GlideApplicationProperty.getValue(MY_APP_PROP_NAME, ACME_DOMAIN_ID));
} catch (e) {
    gs.error('Exception caught: ' + e.name + ' - ' + e.message);
}
```
} catch (ex) {
    gs.info('Exception: ' + ex);
}

// Override the value for Cisco domain -- assuming that the current session domain is Cisco. Notice that we don't pass domain-id explicitly
session.setDomainID(CISCO_DOMAIN_ID); // NOTE: this API is not available from non-global scope (use domain-picker to switch to Cisco)
gs.info('Domain: ' + session.getCurrentDomainID());
GlideApplicationProperty.setValue(MY_APP_PROP_NAME, 'prop-value-Cisco');
gs.info('Value for current session (Cisco) domain: ' + GlideApplicationProperty.getValue(MY_APP_PROP_NAME));

Output:

*** Script: Value for ACME domain: prop-value-ACME
*** Script: Domain: c90f91924a362312001bdefae0f35d68
*** Script: Value for current session (Cisco) domain: prop-value-Cisco

GlideApplicationProperty - setValue(String name, String value, String domainSysId)

Stores the specified value in the specified application property for the specified domain, or the current session domain if not specified.

The following are guidelines for using this method:

- The application property is not created if its name contains one of the following strings:
  - glide.properties.blacklist
  - glide.properties.no_db_override
  - glide.properties.safe_overrides
  - glide.properties.maint_write_roles
- The application property is not created if there is an existing system property with the same name, and the system property is marked as private.
- The application property is not created if there is an existing system property and the application property does not reference it.
- The name of the application property in the sys_application_property table is prefixed with the application's scope if it is not global.
- This method cannot be called from a different scope.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the application property to save.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> If the application is not global, you must prefix the name of</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the sys_application_property with the application's scope.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Value to store in the specified application property.</td>
</tr>
<tr>
<td>domainSysId</td>
<td>String</td>
<td>Optional. Sys_id of the domain associated with the application property.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: Current session domain</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the save operation was successful. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Value was successfully saved.</td>
</tr>
<tr>
<td></td>
<td>• false: An error occurred and the application property was not created/updated.</td>
</tr>
<tr>
<td></td>
<td>If the user does not have access rights to the specified domain, throws an exception and no value is returned.</td>
</tr>
</tbody>
</table>

This example shows how to create a new application property and override its value for ACME and Cisco domains.

```javascript
var MY_APP_PROP_NAME = 'my-app-prop';
var ACME_DOMAIN_ID = 'c90d4b084a362312013398f051272c0d';
var CISCO_DOMAIN_ID = 'c90f91924a362312001bdefae0f35d68';

// create a new app_config entry:
var now_GR = new GlideRecord('sys_application_property');
now_GR.name = MY_APP_PROP_NAME;
now_GR.default_value = 'my-app-prop-default_value';
now_GR.insert();

// Override the value for ACME domain, catch exception if user can't access the specified domain
```
try {
    GlideApplicationProperty.setValue(MY_APP_PROP_NAME, 'prop-value-ACME', ACME_DOMAIN_ID);
    gs.info('Value for ACME domain: ' + GlideApplicationProperty.getValue(MY_APP_PROP_NAME, ACME_DOMAIN_ID));
} catch (ex) {
    gs.info('Exception: ' + ex);
}

// Override the value for Cisco domain -- assuming that the current session domain is Cisco. Notice that we don't pass domain-id explicitly
session.setDomainID(CISCO_DOMAIN_ID); // NOTE: this API is not available from non-global scope (use domain-picker to switch to Cisco)
gs.info('Domain: ' + session.getCurrentDomainID());
GlideApplicationProperty.setValue(MY_APP_PROP_NAME, 'prop-value-Cisco');
gs.info('Value for current session (Cisco) domain: ' + GlideApplicationProperty.getValue(MY_APP_PROP_NAME));

Output:

*** Script: Value for ACME domain: prop-value-ACME
*** Script: Domain: c90f91924a362312001bdefae0f35d68
*** Script: Value for current session (Cisco) domain: prop-value-Cisco

GlideAjax - Client

The GlideAjax class enables a client script to call server-side code in a script include. To use GlideAjax in a client script, follow these general steps.

1. Create a GlideAjax instance by calling the GlideAjax constructor. As the argument to the constructor, specify the name of the script include class that contains the method you want to call.

2. Call the addParam method with the sysparm_name parameter and the name of the script-include method you want to call.

3. (Optional) Call the addParam method one or more times to provide the script-include code with other parameters it needs.
4. Execute the server-side code by calling `getXML()`.

**Note:** `getXML()` is the preferred method for executing the code, because it is asynchronous and does not hold up the execution of other client code. Another method, `getXMLWait()`, is also available but is not recommended. Using `getXMLWait()` ensures the order of execution, but can cause the application to seem unresponsive, significantly degrading the user experience of any application that uses it. `getXMLWait()` is not available to scoped applications.

```javascript
var ga = new GlideAjax('HelloWorld'); // HelloWorld is the script include class
ga.addParam('sysparm_name','helloWorld'); // helloWorld is the script include method
ga.addParam('sysparm_user_name','Bob'); // Set parameter sysparm_user_name to 'Bob'
ga.getXML(HelloWorldParse); /* Call HelloWorld.helloWorld() with the parameter
   sysparm_user_name set to 'Bob'
   and use the callback function HelloWorldParse() to return the result when ready */

// the callback function for returning the result from the server-side code
function HelloWorldParse(response) {
  var answer = response.responseXML.documentElement.getAttribute("answer");
  alert(answer);
}
```

**GlideAjax - getAnswer()**

Retrieves the results from a server-side method called from the client via `getXMLWait()`.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td>The result returned by the server-side method previously called with <code>getXMLWait()</code></td>
</tr>
</tbody>
</table>
GlideAjax - addParam(String parm_name, String parm_value)

Specifies a parameter name and value to be passed to the server-side function associated with this GlideAjax object.

You can execute addParam multiple times with different parameters and values.

⚠️ Note: The first call to addParam should be with the parameter sysparm_name and the name of the server-side method you want to call. The server-side code does not execute until the client script calls getXML().

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>parm_name</td>
<td>String</td>
<td>The name of the parameter to pass. (The name must begin with the sysparm_.)</td>
</tr>
<tr>
<td>parm_value</td>
<td>String</td>
<td>The value to assign to parm_name.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideAjax - getXML(Function callback)

Sends the server a request to execute the method and parameters associated with this GlideAjax object.

The server processes the request asynchronously and -- when ready -- returns the results via the function specified as the callback_function.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callback</td>
<td>Function</td>
<td>The name of the callback function to process the results returned by the server.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
```javascript
var comments = gel("dialog_comments").value;
var ga = new GlideAjax('validateComments'); // Call script include to escape text
ga.addParam('sysparm_name', 'validateComments');
ga.addParam('sysparm_comments', comments);
ga.getXML(callback);

return false;

function callback(response) {
    var comments = response.responseXML.documentElement.getAttribute("answer");
    comments = trim(comments);
    if (comments == "") {
        // If comments are empty, alert the user and stop submission
        alert("Please enter your comments before submitting.");
    } else {
        // If there are comments, close the dialog window and submit them
        GlideDialogWindow.get().destroy(); // Close the dialog window
        g_form.setValue("comments", comments); // Set the "Comments" field with comments in the dialog
    }
}
```

**GlideAjax - getXMLAnswer(Function callback, Object additionalParam, Object responseParam)**

Calls the processor asynchronously and gets the answer element of the response in XML format.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callback</td>
<td>Function</td>
<td>Callback function. The function receives the answer element of the response in XML format as an argument.</td>
</tr>
<tr>
<td>additionalParam</td>
<td>Object</td>
<td>Optional. Name-value pair of additional parameters.</td>
</tr>
<tr>
<td>responseParam</td>
<td>Object</td>
<td>Optional. Second argument for the callback function.</td>
</tr>
</tbody>
</table>

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Returns the number of attachments

```javascript
function updateAttachmentCount(sysid) {
    var ga = new GlideAjax('AttachmentAjax');
    ga.addParam('sysparm_type', 'attachmentCount');
    ga.addParam('sysparm_value', sysid);
    ga.getXMLAnswer(numberOfAttachments, null, sysid); // callback: numberOfAttachments with args (answer, sysid)
}
```

```javascript
function numberOfAttachments(answer, sysid) {
    // we want to know there are 5 attachments, not 5.0 attachments
    var number = parseInt(answer);
    var buttons = $$('.attachmentNumber_' + sysid);
    if (buttons[0] == undefined)
        $('header_attachment_list_label').down().innerHTML = number;
    else {
        for (var i = 0; i < buttons.length; i++) {
            buttons[i].innerHTML = number;
        }
    }
}
```

GlideAjax - getXMLWait()

Sends the server a request to execute the method and parameters associated with this GlideAjax object.

The server processes the request synchronously and will not process further requests from the client until finished. To retrieve the results, the client must call `getAnswer()`. Using `getXMLWait()` ensures the order of execution, but can cause the application to seem unresponsive, significantly degrading the user experience of any application that uses it. We recommend using `getXML()` instead.

⚠️ Note: `getXMLWait()` is not available to scoped applications.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
var ga = new GlideAjax('HelloWorld');
ga.addParam('sysparm_name','helloWorld');
ga.addParam('sysparm_user_name','Bob');
ga.getXMLWait();
alert(ga.getAnswer());
```

Scoped equivalent

`getXMLWait()` is not available to scoped applications. Instead use the `getXML()` method.

GlideAjax - GlideAjax(String class_name)

Constructor for GlideAjax.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>class_name</td>
<td>String</td>
<td>The name of the server-side class that contains the method you want to execute.</td>
</tr>
</tbody>
</table>

GlideAjaxV3 - Client

The GlideAjaxV3 API provides the ability to asynchronously execute server-side scripts from a client-side script.

The GlideAjaxV3 API can be used in client-side scripts using ListV2 and ListV3 APIs.

GlideAjaxV3 - addParam(String name, String value)

Set a name-value pair to be sent to the processor.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the parameter. This usually has the prefix 'sysparm_'</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The parameter value.</td>
</tr>
</tbody>
</table>

### GlideAjaxV3 - getJSON(Function callback)

Call the processor asynchronously and get the answer element of the response in JSON format.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callback</td>
<td>Function</td>
<td>The callback function. The function receives the answer element of the response as a JSON object.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### GlideAjaxV3 - getParam(String name)

Returns the value of the specified parameter.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the parameter to return.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The specified parameter's value.</td>
</tr>
</tbody>
</table>

GlideAjaxV3 - getParams()

Returns the name-value pairs for the request.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The request's name-value pairs.</td>
</tr>
</tbody>
</table>

GlideAjaxV3 - getProcessor()

Returns the server-side script that the request is going to use.

This returns the 'sysparm_processor' parameter.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The value of the request's sysparm_processor parameter.</td>
</tr>
</tbody>
</table>

GlideAjaxV3 - getURL()

Returns the target URL.
### GlideAjaxV3 - getXML(Function callback)

Call the processor asynchronously and get the response in XML format.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callback</td>
<td>Function</td>
<td>The callback function. The function receives the response as an argument.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The URL where the Ajax request will be sent.</td>
</tr>
</tbody>
</table>

### GlideAjaxV3 - getXMLAnswer(Function callback)

Call the processor asynchronously and get the answer element of the response in XML format.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callback</td>
<td>Function</td>
<td>The callback function. The function receives the answer element of the response in XML format as an argument.</td>
</tr>
</tbody>
</table>
function autofillPhoneNumber(sysid) {
    var ga = new GlideAjax('x_abc_myscope.AjaxUtils');
    ga.addParam('sysparm_type', 'getPhoneNumberForUser');
    ga.addParam('sysparm_user', sysid);
    ga.getXMLAnswer(function(answer) {
        g_form.setValue('phone_number', answer);
    });
}

GlideAjaxV3 - GlideAjax(String processor)
Creates an instance of the GlideAjaxV3 class.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>processor</td>
<td>String</td>
<td>The name of the processor (server-side script) to call.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideAjaxV3 - GlideAjax(String processor, String targetURL)
Creates an instance of the GlideAjaxV3 class.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>processor</td>
<td>String</td>
<td>The name of the processor (server-side script) to call.</td>
</tr>
<tr>
<td>targetURL</td>
<td>String</td>
<td>(Optional) Override the xmlhttp processor url. If this parameter is not specified, the default is xmlhttp.do.</td>
</tr>
</tbody>
</table>
**GlideAjaxV3 - setErrorCallback(Function callback)**

Sets a callback function to be called if the Ajax request fails.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callback</td>
<td>Function</td>
<td>The function to be called if the Ajax request fails. The callback function has one parameter, the XMLHttpRequest object.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideAjaxV3 - setProcessor(String serverScript)**

Sets the request's server-side script. The server-side script is also called the processor.

This sets the 'sysparm_processor' parameter.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>serverScript</td>
<td>String</td>
<td>The server-side script (processor) to receive the request.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
**GlideappCalculationHelper - Global**

The GlideappCalculationHelper API is a scriptable object that provides methods that add items to an existing request or request the recalculation of the price of a request.

The methods for this API are used in global server-side scripts (script includes, business rules, etc.). There is currently no support for scoped applications.

**GlideappCalculationHelper - addItemToExistingRequest(String requestID, String catalogID, String quantity)**

Adds a specific catalog item to an existing request. This API should be used only before a request (REQ) is approved. After the REQ is approved, the RITM process is not initiated.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestID</td>
<td>String</td>
<td>Sys_id of the request to which to add the catalog item(s)</td>
</tr>
<tr>
<td>catalogID</td>
<td>String</td>
<td>Sys_id of the catalog item to add to the request</td>
</tr>
<tr>
<td>quantity</td>
<td>String</td>
<td>Number (quantity) of the specified catalog item to be add to the request</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var catItemId = "04b7e94b4f7b4200086eeed18110c7fd";
var requestId = "6eed229047801200e0ef563dbb9a71c2";
var helper = new GlideappCalculationHelper();
helper.addItemToExistingRequest(requestId, catItemId, "1");
```

**GlideappCalculationHelper - rebalanceRequest(String requestID)**

Recalculates the price of all of the items in a specified request.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestID</td>
<td>String</td>
<td>Sys_id of the request for which to recalculate the price</td>
</tr>
</tbody>
</table>
var catItemId = "04b7e94b4f7b4200086eed18110c7fd";
var requestId = "6eed229047801200e0ef563dbb9a71c2";
var helper = new GlideappCalculationHelper();
// Add an item to the request
helper.addItemToExistingRequest(requestId, catItemId, "1");
// Re-calculate the price of the request after adding the item
helper.rebalanceRequest(requestId);

**GlideCalendarDateTime - Scoped**

The GlideCalendarDateTime class provides methods for performing operations on GlideCalendarDateTime objects, such as instantiating GlideCalendarDateTime objects or working with glide_date_time fields.

Use the GlideCalendarDateTime methods to perform date-time operations, such as instantiating a GlideCalendarDateTime object, performing date-time calculations, formatting a date-time, or converting between date-time formats.

**GlideCalendarDateTime - add(GlideTime time)**

Adds a GlideTime object to the current GlideCalendarDateTime object.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>GlideTime</td>
<td>Time to add.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
GlideCalendarDateTime - add(Number milliseconds)

Adds a specified number of milliseconds to the GlideCalendarDateTime object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>Number of milliseconds to add</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideCalendarDateTime - addDaysLocalTime(Number days)

Adds a specified number of days to the current GlideCalendarDateTime object. A negative parameter subtracts days.

The method determines the local date and time equivalent to the value stored by the GlideCalendarDateTime object, then adds or subtracts days using the local date and time values.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>Number</td>
<td>Number of days to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gcdt.addDaysLocalTime(-1);
gs.info(gcdt.getLocalDate());
```

Output:

2011-08-30

**GlideCalendarDateTime - addDaysUTC(Number days)**

Adds a specified number of days to the current GlideCalendarDateTime object. A negative parameter subtracts days.

The method determines the UTC date and time equivalent to the value stored by the GlideCalendarDateTime object, then adds or subtracts days using the UTC date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>Number</td>
<td>Number of days to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gcdt.addDaysUTC(-1);
gs.info(gcdt.getDate());
```
GlideCalendarDateTime - addMonthsLocalTime(Number months)

Adds a specified number of months to the current GlideCalendarDateTime object. A negative parameter subtracts months.

The method determines the local date and time equivalent to the value stored by the GlideCalendarDateTime object, then adds or subtracts months using the local date and time values.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>Number of months to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gcdt.addMonthsLocalTime(2);
gs.info(gcdt.getDate());
```

Output:

2011-10-31

GlideCalendarDateTime - addMonthsUTC(Number months)

Adds a specified number of months to the current GlideCalendarDateTime object. A negative parameter subtracts months.

The method determines the UTC date and time equivalent to the value stored by the GlideCalendarDateTime object, then adds or subtracts months using the UTC date and time values.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>Number of months to add. Use a negative number to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gcdt.addMonthsUTC(2);
gs.info(gcdt.getDate());

Output:

2011-10-31
```

**GlideCalendarDateTime - addSeconds(Number seconds)**

Adds a specified number of seconds to the GlideCalendarDateTime object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seconds</td>
<td>Number</td>
<td>Number of seconds to add</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-12-07 08:00:00");
gcdt.addSeconds(1000);
gs.info(gcdt.getValue());

Output:

2011-12-07 08:16:40
```
GlideCalendarDateTime - addWeeksLocalTime(Number weeks)

Adds a specified number of weeks to the current GlideCalendarDateTime object. A negative parameter subtracts weeks.

The method determines the local date and time equivalent to the value stored by the GlideCalendarDateTime object, then adds or subtracts weeks using the local date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>weeks</td>
<td>Number</td>
<td>Number of weeks to add. Use a negative number to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gcdt.addWeeksLocalTime(-1);
gs.info(gcdt.getDate());
```

Output:

2011-08-24

GlideCalendarDateTime - addWeeksUTC(Number weeks)

Adds a specified number of weeks to the current GlideCalendarDateTime object. A negative parameter subtracts weeks.

The method determines the UTC date and time equivalent to the value stored by the GlideCalendarDateTime object, then adds or subtracts weeks using the UTC date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>weeks</td>
<td>Number</td>
<td>Number of weeks to add. Use a negative number to subtract.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gcdt.addWeeksUTC(-1);
gs.info(gcdt.getDate());
```

Output:

2011-08-24

**GlideCalendarDateTime - addYearsLocalTime(Number years)**

Adds a specified number of years to the current GlideCalendarDateTime object. A negative parameter subtracts years.

The method determines the local date and time equivalent to the value stored by the GlideCalendarDateTime object, then adds or subtracts years using the local date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>years</td>
<td>Number</td>
<td>Number of years to add. To subtract use a negative value.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2010-08-31 08:00:00");
gcdt.addYearsLocalTime(1);
gs.info(gcdt.getDate());
```

Output:

2011-08-31
GlideCalendarDateTime - addYearsUTC(Number years)

Adds a specified number of years to the current GlideCalendarDateTime object. A negative parameter subtracts years.

The date and time value stored by GlideCalendarDateTime object is interpreted as being in the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>years</td>
<td>Number</td>
<td>Number of years to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```
var gcdt = new GlideCalendarDateTime("2010-08-31 08:00:00");
gcdt.addYearsUTC(1);
gs.info(gcdt.getDate());
```

Output:

2011-08-31

GlideCalendarDateTime - after(GlideCalendarDateTime gdt)

Determines if the GlideCalendarDateTime object's date and time occurs after the specified GlideCalendarDateTime object's date and time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gdt</td>
<td>GlideCalendarDateTime</td>
<td>Date and time to check against.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the GlideCalendarDateTime object's date and time is after the date and time specified by the parameter. Possible values:</td>
</tr>
</tbody>
</table>

var gcdt = new GlideCalendarDateTime("2010-08-31 08:00:00");
gcdt.addYearsUTC(1);
gs.info(gcdt.getDate());
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• true: GlideCalendarDateTime object date and time is after the specified object's date and time.</td>
<td></td>
</tr>
<tr>
<td>• false: GlideCalendarDateTime object date and time is before or equal to the specified object's date and time.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt1 = new GlideCalendarDateTime("2016-05-09 10:11:12");
var gdt2 = new GlideCalendarDateTime("2015-06-12 15:11:12");
gs.info(gdt1.after(gdt2));
```

**Output**

```
true
```

### GlideCalendarDateTime - before(GlideCalendarDateTime gdt)

Determines if the GlideCalendarDateTime object's date and time occurs before the specified GlideCalendarDateTime object's date and time.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gdt</td>
<td>GlideCalendarDateTime</td>
<td>Date and time to check against.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the GlideCalendarDateTime object's date and time is before the date and time specified by the parameter. Possible values:</td>
</tr>
<tr>
<td>• true: GlideCalendarDateTime object date and time is before the specified object's date and time.</td>
<td></td>
</tr>
<tr>
<td>• false: GlideCalendarDateTime object date and time is after or equal to the specified object's date and time.</td>
<td></td>
</tr>
</tbody>
</table>
var gdt1 = new GlideCalendarDateTime("2016-05-09 10:11:12");
var gdt2 = new GlideCalendarDateTime("2015-06-12 15:11:12");
gs.info(gdt1.before(gdt2));

Output
false

GlideCalendarDateTime - compareTo(Object dateTime)
Compares two date and time objects to determine whether one occurs before the other or if they are equivalent.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>Object</td>
<td>Date time in a GlideCalendarDateTime object.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>• 0 = Dates are equal</td>
</tr>
<tr>
<td></td>
<td>• 1 = Object's date is after the date specified in the parameter</td>
</tr>
<tr>
<td></td>
<td>• -1 = Object's date is before the date specified in the parameter</td>
</tr>
</tbody>
</table>

var initDate = new GlideCalendarDateTime("2011-08-01 12:00:00");
var compDate1 = new GlideCalendarDateTime("2011-08-01 12:00:00");
var compDate2 = new GlideCalendarDateTime("2011-07-31 12:00:00");
var compDate3 = new GlideCalendarDateTime("2011-08-04 16:00:00");

gs.info(initDate.compareTo(compDate1)); // Equals (0)
gs.info(initDate.compareTo(compDate2)); // initDate is after compDate2 (1)
gs.info(initDate.compareTo(compDate3)); // initDate is before compDate3 (-1)

GlideCalendarDateTime - equals(Object GCDT)
Compares an object with an existing value for equality.
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GCDT</td>
<td>Object</td>
<td>Object to compare. Can be a GlideCalendarDateTime object or a valid date time string.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if they are equal, false otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 00:00:00");
gs.info(gcdt.equals("2011-09-30 00:12:01"));
```

Output:

false

---

**GlideCalendarDateTime - getDate()**

Returns the date stored by the GlideCalendarDateTime object, expressed in the standard format, yyyy-MM-dd, and the system time zone, UTC by default.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDate</td>
<td>Date in the system time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.getDate());
```

Output:

2011-08-31
GlideCalendarDateTime - getDayOfMonthLocalTime()

Returns the day of the month stored by the GlideCalendarDateTime object, expressed in the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Day of the month in the user's time zone, from 1 to 31.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-12-02 12:00:00");
gs.info(gcdt.getDayOfMonthLocalTime());
```

Output:

2

GlideCalendarDateTime - getDayOfMonthUTC()

Gets the day of the month stored by the GlideCalendarDateTime object, expressed in the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Day of the month in the UTC time zone, from 1 to 31.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-12-02 12:00:00");
gs.info(gcdt.getDayOfMonthUTC());
```

Output:
GlideCalendarDateTime - getDayOfWeekLocalTime()

Returns the day of the week stored by the GlideCalendarDateTime object, expressed in the user's time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Day of the week value - Monday = 1, ... Sunday = 7</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-12-01 12:00:00");
gs.info(gcdt.getDayOfWeekLocalTime());
```

Output:

4

GlideCalendarDateTime - getDayOfWeekUTC()

Returns the day of the week stored by the GlideCalendarDateTime object, expressed in the UTC time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Day of the week value - Monday = 1, ... Sunday = 7</td>
</tr>
</tbody>
</table>

1947
```javascript
var gcdt = new GlideCalendarDateTime("2011-12-01 12:00:00");
gs.info(gcdt.getDayOfWeekUTC());
```

Output:

4

### GlideCalendarDateTime - getDaysInMonthLocalTime()

Returns the number of days in the month stored by the GlideCalendarDateTime object, expressed in the current user’s time zone.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of days in the current month in the user’s time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime(); //December
gs.info(gcdt.getDaysInMonthLocalTime());
```

Output:

31

### GlideCalendarDateTime - getDaysInMonthUTC()

Returns the number of days in the month stored by the GlideCalendarDateTime object, expressed in the UTC time zone.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of days in the month stored by the GlideCalendarDateTime object, expressed in the UTC time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime(); //December
gs.info(gcdt.getDaysInMonthUTC());
```

**Output:**

31

### GlideCalendarDateTime - getDisplayValue()

Returns the date and time value in the current user's display format and time zone. Referring to the GlideCalendarDateTime object directly returns the date and time value in the GMT time zone.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Date and time in the user's format and time zone. Keep in mind when designing business rules or script includes that this method may return values in different formats for different users.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.getDisplayValue());
```

**Output:**

2011-08-31 01:00:00

### GlideCalendarDateTime - getDisplayValueInternal()

Returns the display value in the internal format (yyyy-MM-dd HH:mm:ss).
This method is useful for date/time fields, but not for date fields.

### Parameters
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Date and time values for the GlideCalendarDateTime object in the current user's time zone and the internal date and time format of yyyy-MM-dd HH:mm:ss.</td>
</tr>
</tbody>
</table>

```java
// Wednesday
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.getDisplayValueInternal());
```

**Output:**

```
2011-08-31 01:00:00
```

#### GlideCalendarDateTime - getDSTOffset()

Returns the amount of time that daylight saving time is offset.

### Parameters
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Amount of time, in milliseconds, that daylight saving is offset. Returns 0 if there is no offset or if the time is not during daylight saving time.</td>
</tr>
</tbody>
</table>

```java
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.getDSTOffset());
```

**Output:**

```
```
GlideCalendarDateTime - getErrorMsg()

Returns the current error message.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Error message</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 aa:00:00"); //bad
gs.info(gcdt.isValid()); //false
gs.info(gcdt.getErrorMsg()); //reason
```

Output:

false
Could not parse DateTime: 2011-08-31 aa:00:00

GlideCalendarDateTime - getInternalFormattedLocalTime()

Returns the object's time in the local time zone and in the internal format.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Object's time in the local time zone and the internal format.</td>
</tr>
</tbody>
</table>

var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.getInternalFormatedLocalTime());

Output:
2011-08-31 08:00:00

GlideCalendarDateTime - getLocalDate()

Returns the date stored by the GlideCalendarDateTime object, expressed in the standard format, yyyy-MM-dd, and the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDate</td>
<td>Date in the user's time zone.</td>
</tr>
</tbody>
</table>

var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.getLocalDate());

Output:
2011-08-31

GlideCalendarDateTime - getMonthLocalTime()

Returns the month stored by the GlideCalendarDateTime object, expressed in the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### GlideCalendarDateTime - getMonthLocalTime()

Returns the month stored by the GlideCalendarDateTime object, expressed in the UTC time zone.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Numerical value of the month, Jan=1, Dec=12.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime(); //December
gs.info(gcdt.getMonthLocalTime());
```

Output:

```
12
```

### GlideCalendarDateTime - getMonthUTC()

Returns the month stored by the GlideCalendarDateTime object, expressed in the UTC time zone.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Numerical value of the month, Jan=1, Dec=12.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime(); //December
gs.info(gcdt.getMonthUTC());
```

Output:

```
12
```

### GlideCalendarDateTime - getNumericValue()

Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of milliseconds since January 1, 1970, 00:00:00 GMT.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.getNumericValue());
```

Output:

```plaintext
1314777600000
```

**GlideCalendarDateTime - getTime()**

Returns the Unix duration stamp.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideTime</td>
<td>Unix duration stamp in system format based on GMT time.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.getTime());
```

Output:

```plaintext
1970-01-01 08:00:00
```

**GlideCalendarDateTime - getTZOffset()**

Returns the time zone offset in milliseconds.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of milliseconds of the time zone offset</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime();
gcdt.getLocalTime(); // PST local time
gs.info(gcdt.getTZOffset());
```

Output:

```
-28800000
```

**GlideCalendarDateTime - getUserFormattedLocalTime()**

Returns the object's time in local time zone in the user's format.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Object's time in local time and the user's format.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.getUserFormatedLocalTime());
```

Output:

```
2011-08-31 05:00:00
```
**GlideCalendarDateTime - getValue()**

Returns the date and time value stored by the GlideCalendarDateTime object in the internal format, yyyy-MM-dd HH:mm:ss, and the system time zone; UTC by default.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.getValue());
```

Output:

```
2011-08-31 08:00:00
```

**GlideCalendarDateTime - getWeekOfYearLocalTime()**

Returns the number of the week stored by the GlideCalendarDateTime object, expressed in the current user's time zone.

All weeks begin on Sunday. The first week of the year is the week that contains at least one day of the new year. The week beginning Sunday 2015-12-27 is considered the first week of 2016 as that week contains January 1 and 2.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of the current week. The highest week number in a year is either 52 or 53.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-12-01 12:00:00");
gs.info(gcdt.getWeekOfYearUTC());
```

Output:

49

### GlideCalendarDateTime - getWeekOfYearUTC()

Returns the number of the week stored by the GlideCalendarDateTime object, expressed in the UTC time zone.

All weeks begin on Sunday. The first week of the year is the week that contains at least one day of the new year. The week beginning Sunday 2015-12-27 is considered the first week of 2016 as that week contains January 1 and 2.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of the current week in UTC time. The highest week number in a year is either 52 or 53.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-12-01 12:00:00");
gs.info(gcdt.getWeekOfYearUTC());
```

Output:

49
GlideCalendarDateTime - getYearLocalTime()

Returns the year stored by the GlideCalendarDateTime object, expressed in the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Four-digit year value in the user's time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime(); //2011
gs.info(gcdt.getYearLocalTime());
```

Output:

2011

GlideCalendarDateTime - getYearUTC()

Returns the year stored by the GlideCalendarDateTime object, expressed in the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number</td>
<td>Four-digit year value in the UTC time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime(); //2011
gs.info(gcdt.getYearUTC());
```

Output:
GlideCalendarDateTime - GlideCalendarDateTime()

Instantiates a new GlideCalendarDateTime object with the current date and time in GMT format.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime();
```

GlideCalendarDateTime - GlideCalendarDateTime(GlideCalendarDateTime gcDT)

Instantiates a new GlideCalendarDateTime object set to the time of a specified GlideCalendarDateTime object in GMT format.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gcDT</td>
<td>GlideCalendarDateTime</td>
<td>Object used to set the time of the new object.</td>
</tr>
</tbody>
</table>

```javascript
var start = new GlideCalendarDateTime("2011-01-01 12:00:00");
var end = new GlideCalendarDateTime(start);
gs.info(end);
```

Output:

```
2011-01-01 12:00:00
```

GlideCalendarDateTime - GlideCalendarDateTime(String dateTime)

Instantiates a new GlideCalendarDateTime object from a date and time value in the UTC time zone specified with the format yyyy-MM-dd HH:mm:ss.
### GlideCalendarDateTime - hasDate()

Determines if an object's date is set.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the object's date is set, false otherwise.</td>
</tr>
</tbody>
</table>

```
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.hasDate());
```

Output:

```
true
```

### GlideCalendarDateTime - isDST()

Determines if the object's time uses a daylight saving offset.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.isDST());
```
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the time is daylight saving time, false otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 00:00:00");
gs.info(gcdt.isDST()); //true
```

Output:

```javascript
true
```

GlideCalendarDateTime - isValid()

Determines if a value is a valid date and time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if value is valid, false otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 aa:00:00"); //bad
gs.info(gcdt.isValid()); //false
```

Output:

```javascript
false
```

GlideCalendarDateTime - onOrAfter(GlideCalendarDateTime gdt)

Determines if the GlideCalendarDateTime object's data and time occurs on or after the specified GlideCalendarDateTime object's date and time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gdt</td>
<td>GlideCalendarDateTime</td>
<td>Date and time to check against.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the GlideCalendarDateTime object's date and time is on or after the date and time specified by the parameter.</td>
</tr>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: GlideCalendarDateTime object date and time is on or after the specified object's date and time.</td>
</tr>
<tr>
<td></td>
<td>• false: GlideCalendarDateTime object date and time is before the specified object's date and time.</td>
</tr>
</tbody>
</table>

```javascript
var gdt1 = new GlideCalendarDateTime("2016-05-09 10:11:12");
var gdt2 = new GlideCalendarDateTime("2017-06-12 15:11:12");
gs.info(gdt1.onOrAfter(gdt2));
```

Output

defalse

`GlideCalendarDateTime - onOrBefore(GlideCalendarDateTime gdt)`

Determines if the GlideCalendarDateTime object's data and time occurs on or before the specified GlideCalendarDateTime object's date and time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gdt</td>
<td>GlideCalendarDateTime</td>
<td>Date and time to check against.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the GlideCalendarDateTime object's date and time is on or before the date and time specified by the parameter.</td>
</tr>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: GlideCalendarDateTime object date and time is on or before the specified object's date and time.</td>
</tr>
<tr>
<td></td>
<td>• false: GlideCalendarDateTime object date and time is after the specified object's date and time.</td>
</tr>
</tbody>
</table>
var gdt1 = new GlideCalendarDateTime("2016-05-09 10:11:12");
var gdt2 = new GlideCalendarDateTime("2017-06-12 15:11:12");
gs.info(gdt1.onOrBefore(gdt2));

Output:

true

GlideCalendarDateTime - setDayOfMonthLocalTime(Number day)
Sets the day of the month to a specified value in the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>day</td>
<td>Number</td>
<td>Day of month to change to, from 1 to 31. If this value is greater than the maximum number of days in the month, the value is set to the last day of the month.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gcdt = new GlideCalendarDateTime();
gcdt.setDayOfMonthLocalTime(9);
gs.info(gcdt.getDayOfMonthLocalTime());

Output:

9

GlideCalendarDateTime - setDayOfMonthUTC(Number day)
Sets the day of the month to a specified value in the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>day</td>
<td>Number</td>
<td>Day of month to change to, from 1 to 31. If this value is greater than the maximum number of days in the month, the value is set to the last day of the month.</td>
</tr>
</tbody>
</table>
**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gcdt = new GlideCalendarDateTime();
gcdt.setDayOfMonthUTC(9);
gs.info(gcdt.getDayOfMonthUTC());

Output:

9

**GlideCalendarDateTime - setDisplayValue(String asDisplayed)**

Sets a date and time value using the current user's display format and time zone.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| asDisplayed | String | Date and time in the current user's display format and time zone.  

The parameter must be formatted using the current user's preferred display format, such as MM-dd-yyyy HH:mm:ss.  

To assign the current date and time to a variable in a workflow script, use `<variable>.setDisplayValue(gs.nowDateTime)`.

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gcdt = new GlideCalendarDateTime("2011-02-02 12:00:00");
gcdt.setDisplayValue("2011-01-01 12:00:00");
gs.info(gcdt.getValue());

Output:

2011-01-01 20:00:00
**GlideCalendarDateTime - setDisplayValue(String dateTime, String format)**

Sets a date and time value using the current user's time zone and the specified date and time format.

This method throws a runtime exception if the date and time format in the dateTime parameter does not match the format parameter. You can retrieve the error message by calling `getErrorMsg()` on the GlideCalendarDateTime object after the exception is caught.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>String</td>
<td>Date and time in the current user's time zone.</td>
</tr>
<tr>
<td>format</td>
<td>String</td>
<td>Format to use to parse the dateTime parameter.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-02-02 12:00:00");
gcdt.setDisplayValue("20-5-2011 12:00:00", "dd-MM-yyyy HH:mm:ss");
gs.info(gcdt.getValue());
```

**Output:**

| 2011-05-20 19:00:00 |

**GlideCalendarDateTime - setDisplayValueInternal(String dateTime)**

Sets a date and time value using the internal format (yyyy-MM-dd HH:mm:ss) and the current user's time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>String</td>
<td>Date and time in internal format</td>
</tr>
</tbody>
</table>
**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-02-02 12:00:00");
gcdt.setDisplayValueInternal("2011-01-01 12:00:00");
gs.info(gcdt.getValue());
```

Output:

```
2011-01-01 20:00:00
```

**GlideCalendarDateTime - setGlideDateTime(GlideCalendarDateTime gcDT)**

Sets the date and time of the current object using an existing GlideCalendarDateTime object.

This method is equivalent to instantiating a new object with a GlideCalendarDateTime parameter.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gcDT</td>
<td>GlideCalendarDateTime</td>
<td>GlideCalendarDateTime object</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var dt1 = new GlideCalendarDateTime("2011-01-01 12:00:00");
var dt2 = new GlideCalendarDateTime("2011-02-02 08:00:00");
dt1.setGlideDateTime(dt2);
gs.info(dt1.getValue());
```

Output:

```
2011-02-02 08:00:00
```
GlideCalendarDateTime - setMonthLocalTime(Number month)

Sets the month stored by the GlideCalendarDateTime object to a specified value using the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>month</td>
<td>Number</td>
<td>Month to change to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime();
gcdt.setMonthLocalTime(1);
gs.info(gcdt.getMonthLocalTime());
```

Output:

```
1
```

GlideCalendarDateTime - setMonthUTC(Number month)

Sets the month stored by the GlideCalendarDateTime object to a specified value using the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>month</td>
<td>Number</td>
<td>Month to change to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime();
gcdt.setMonthUTC(1);
gs.info(gcdt.getMonthUTC());
```
GlideCalendarDateTime - setValue(Object dateTime)

Sets the date and time of the GlideCalendarDateTime object.

This method is equivalent to setInitialValue().

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>Object</td>
<td>Date and time to use. This parameter may be one of several types.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A string in the UTC time zone and the internal format of yyyy-MM-dd HH:mm:ss: sets the value of the object to the specified date and time. Using the method this way is equivalent to instantiating a new GlideCalendarDateTime object using the GlideCalendarDateTime(value) constructor. If the date and time format used does not match the internal format, the method attempts to set the date and time using other available formats. Resolving the date and time this way can lead to inaccurate data due to ambiguity in the day and month values. When using a non-standard date and time format, use setValue(dt, format) instead.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A GlideCalendarDateTime object: sets the value of the object to the date and time stored by the GlideCalendarDateTime passed in the parameter. Using the method this way is equivalent to instantiating a new GlideCalendarDateTime object using the GlideCalendarDateTime(g) constructor.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A Java Date object: sets the value of the object using the value stored by the Java Date object. Using the method this way is equivalent to passing the value returned by the Java Date object getTime() to the GlideCalendarDateTime setNumericValue() method. This method does not accept JavaScript Date objects.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
|      |      | - A JavaScript Number: sets the value of the object using the Number value as milliseconds past January 1, 1970 00:00:00 GMT. Using the method this way is equivalent to the `setNumericValue(milliseconds)` method. 
|      |      | - A Java Integer or Long: sets the value of the object using the Integer or Long value as milliseconds past January 1, 1970 00:00:00 GMT. Using the method this way is equivalent to the `setNumericValue(milliseconds)` method. |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-01-01 12:00:00");
gcdt.setValue("2011-02-02 08:00:00");
gs.info(gcdt.getValue());
```

Output:

```
2011-02-02 08:00:00
```

**GlideCalendarDateTime - setValueUTC(String dateTime, String format)**

Sets a date and time value using the UTC time zone and the specified date and time format.

This method throws a runtime exception if the date and time format used in the `dateTime` parameter does not match the `format` parameter. You can retrieve the error message by calling `getErrorMsg()` on the GlideCalendarDateTime object after the exception is caught.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>String</td>
<td>Date and time to use.</td>
</tr>
<tr>
<td>format</td>
<td>String</td>
<td>Format to use.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-01-01 12:00:00");
gcdt.setValueUTC("15-02-2011 08:00:00", "dd-MM-yyyy HH:mm:ss");
gs.info(gcdt.getValue());
```

Output:

2011-02-15 08:00:00

GlideCalendarDateTime - setYearLocalTime(Number year)

Sets the year stored by the GlideCalendarDateTime object to a specified value using the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>Number</td>
<td>Year to change to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime();
gcdt.setYearLocalTime(2013);
gs.info(gcdt.getYearLocalTime());
```

Output:

2013
GlideCalendarDateTime - setYearUTC(Number year)

Sets the year stored by the GlideCalendarDateTime object to a specified value using the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>Number</td>
<td>Year to change to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime();
gcdt.setYearUTC(2013);
gs.info(gcdt.getYearUTC());
```

Output:

```
2013
```

GlideCalendarDateTime - subtract(GlideCalendarDateTime start, GlideCalendarDateTime end)

Returns the duration difference between two GlideCalendarDateTime values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>GlideCalendarDateTime</td>
<td>Start value.</td>
</tr>
<tr>
<td>end</td>
<td>GlideCalendarDateTime</td>
<td>End value.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDuration</td>
<td>Time between the two values.</td>
</tr>
</tbody>
</table>
var gcdt1 = new GlideCalendarDateTime("2011-08-28 09:00:00");
var gcdt2 = new GlideCalendarDateTime("2011-08-31 08:00:00");
var dur = new GlideDuration();

var dur = GlideCalendarDateTime.subtract(gcdt1, gcdt2); //the difference between gcdt1 and gcdt2
gs.info(dur.getDisplayValue());

Output:

2 Days 23 Hours

GlideCalendarDateTime - subtract(GlideTime time)
Subtracts a specified amount of time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>GlideTime</td>
<td>Time to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
var gtime1 = new GlideTime();
gtime1.setValue("00:00:20");
gcdt.subtract(gtime1);
gs.info(gcdt.getTime());

Output:

1970-01-01 07:59:40

GlideCalendarDateTime - subtract(Number milliseconds)
Subtracts a specified number of milliseconds from the GlideCalendarDateTime object.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>Number of milliseconds to subtract.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-12-07 08:00:00");
gcdt.subtract(1000);
gs.info(gcdt.getValue());
```

**Output:**

```
2011-12-07 07:59:59
```

### GlideCalendarDateTime - toString()

Returns the date and time value stored by the GlideCalendarDateTime object in the internal format, `yyyy-MM-dd HH:mm:ss`, and the system time zone; UTC by default.

This method is equivalent to `getValue()`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Date and time stored by the GlideCalendarDateTime object in the system time zone and format.</td>
</tr>
</tbody>
</table>

```javascript
var gcdt = new GlideCalendarDateTime("2011-08-31 08:00:00");
gs.info(gcdt.toString());
```

**Output:**

```
2011-08-31 08:00:00
```
GlideCertificateEncryption - Global

APIs available for encrypting certificates.

Use these methods to generate a hash for the certificate, sign data using a private key, and generate a message authentication code.

GlideCertificateEncryption - generateMac(String key, String algorithm, String data)

Generates the Message Authentication Code (MAC), which is used to authenticate a message.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Key to use to sign the message. Must be Base64 encoded.</td>
</tr>
<tr>
<td>algorithm</td>
<td>String</td>
<td>Algorithm to use to generate the MAC: HmacSHA256, HmacSHA1, HmacMD5, and so on.</td>
</tr>
<tr>
<td>data</td>
<td>String</td>
<td>Data to process.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>MAC in base64 format.</td>
</tr>
</tbody>
</table>

### Example

```javascript
var mac = new GlideCertificateEncryption;
var key = "sample_key";
key = GlideStringUtil.base64Encode(key);
mac.generateMac(key, "HmacSHA256", "sample_data");
```

### Scoped equivalent

To use the `generateMac()` method in a scoped application, use the corresponding scoped method: `CertificateEncryption - generateMac(String key, String algorithm, String data)`. 
GlideCertificateEncryption - getThumbPrint(String certificateID, String algorithm)
Generates a hash (SHA-1, SHA-256, and so on) for the certificate from Trust Store Cert.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>algorithm</td>
<td>String</td>
<td>SHA-1, SHA-256, and so on</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Thumbprint in base64 format.</td>
</tr>
</tbody>
</table>

Scoped equivalent
To use the getThumbPrint() method in a scoped application, use the corresponding scoped method: CertificateEncryption - getThumbPrint(String certificateID, String algorithm).

GlideCertificateEncryption - getThumbPrintFromKeystore(String certificateID, String alias, String algorithm)
Generates a hash (SHA-1, SHA-256, and so on) for the certificate from the key store entry.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alias</td>
<td>String</td>
<td>Alias name for the certificate.</td>
</tr>
<tr>
<td>algorithm</td>
<td>String</td>
<td>SHA-1, SHA-256, and so on.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Thumbprint in base64 format.</td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the `getThumbPrintFromKeystore()` method in a scoped application, use the corresponding scoped method: `CertificateEncryption - getThumbPrintFromKeystore(String certificateID, String alias, String algorithm)`.

Instantiates a GlideCertificateEncryption object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Scoped equivalent

**GlideCertificateEncryption - sign(String certificateID, String alias, String aliaspassword, String algorithm, String datatosign)**

Signs the data using the private key and the given algorithm.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alias</td>
<td>String</td>
<td>Private key name.</td>
</tr>
<tr>
<td>aliaspassword</td>
<td>String</td>
<td>Password for the private key.</td>
</tr>
<tr>
<td>datatosign</td>
<td>String</td>
<td>Data to sign.</td>
</tr>
<tr>
<td>algorithm</td>
<td>String</td>
<td>SHA-1, SHA-256, and so on.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Signed data in base64 format.</td>
</tr>
</tbody>
</table>

```javascript
var gce = new GlideCertificateEncryption;
gce.sign("recordID", "alias", "password", "SHA-1", "sign this data");
```

Scoped equivalent
To use the `sign()` method in a scoped application, use the corresponding scoped method: `CertificateEncryption - sign(String certificateID, String alias, String aliaspassword, String algorithm, String datatosign)`.

GlideConversation - Global
The GlideConversation API provides access to information in a Connect message.

**Important:**
Starting with the Paris release, Connect Support no longer receives enhancements or non-priority bug fixes. Consider moving to ServiceNow® Advanced Work Assignment and Agent Chat in workspace to automatically assign chat requests and other work items to agents. For details, see Move from Connect Support to Advanced Work Assignment and Agent Chat.

GlideConversation properties are accessed through a global object (conversation) that is available only in Connect action conditions and scripts. Connect conversations are stored on the Live Group Profile [live_group_profile] table.

GlideConversation - description
The conversation's description.

```javascript
var c = conversation.description;
```

Field

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>String</td>
<td>The conversation's description.</td>
</tr>
</tbody>
</table>

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
**GlideConversation - document**

The sysID of the document associated with the conversation.

This field is set for feed conversations, and contains the sysID of the record being discussed.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>document</td>
<td>GlideRecord</td>
<td>The document associated with the conversation.</td>
</tr>
</tbody>
</table>

**GlideConversation - name**

The name of the conversation.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the conversation.</td>
</tr>
</tbody>
</table>

```javascript
var c = conversation.name;
```

**GlideConversation - queueEntry**

The queue entry associated with the conversation.

The queue entry is a reference field pointing to the chat_queue_entry table. This field is only available on support conversations. The queue chat entry is used to track the state of the conversation. This property is not changed if an incident record is created from the support conversation using the `newRecord()` method.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>queueEntry</td>
<td>GlideRecord</td>
<td>The queue entry associated with the conversation.</td>
</tr>
</tbody>
</table>

```javascript
var c = conversation.queueEntry;
```

**GlideConversation - sys_id**

The sys_id of the conversation.
Field

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>String</td>
<td>The sys_id of the conversation.</td>
</tr>
</tbody>
</table>

```
var c = conversation.sys_id;
```

GlideConversation - table
The name of the table containing the record being discussed.
This field is set for feed conversations, and is set to the table holding the record.

Field

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>The name of the table holding the record being discussed.</td>
</tr>
</tbody>
</table>

```
var c = conversation.table;
```

GlideConversation - type
The conversation type.
This is not the message type.
Connect supports the following types.
- peer - direct conversations, which consist of messages between two users.
- connect - group conversations, which consist of messages between more than two users.
- support - Connect Support conversations.
- feed - record conversations, which consist of messages that correspond to comments and work notes on a specific record.

Field

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>The conversation type.</td>
</tr>
</tbody>
</table>

```
var c = conversation.type;
```
GlideCurrencyConfig - Scoped

The GlideCurrencyConfig API provides methods to retrieve various configuration information for FX Currency fields.

You can acquire information for a specific FX Currency field by calling the GlideCurrencyConfig - GlideCurrencyConfig(Object ed) constructor, which associates a specific FX Currency field to the instantiated object. When calling the various GlideCurrencyConfig() methods, if a record exists in the FX Currency Configuration [fx_configuration] table for the FX Currency field, the requested value is passed back. If a record or field is not available, the default value is passed back. You can also acquire the default FX Currency configuration values by calling the GlideCurrencyConfig - GlideCurrencyConfig() constructor.

For additional information on FX Currency configuration, see Setting up and operating FX Currency fields.

This class uses the sn_currency namespace.

GlideCurrencyConfig - getAggregationSource()

Returns the aggregation source value for an FX Currency field.

If called on an existing FX Currency field that has a corresponding FX Currency Configuration [fx_configuration] record, returns the value of the Aggregation Source (aggregation_source) field. Otherwise, if a new record, returns a default value.

For more information on aggregation source, see Specify the table field and its currency display parameters.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>by the GlideElementDescriptor passed in the constructor. If no fx_configuration record, follows the GlideCurrencyConfig() rules.</td>
</tr>
<tr>
<td>GlideCurrencyConfig()</td>
<td>If set, returns the value in the glide.currency2.aggregation_source field in system properties. Otherwise, returns a hard-coded default of reference.</td>
</tr>
</tbody>
</table>

Possible values:
- default
- as_entered
- reference

This code example returns the default aggregation source.

```javascript
var cur_config = new sn_currency.GlideCurrencyConfig();
var curr_agg_source = cur_config.getAggregationSource();
```

This code example returns the aggregation source for a specific FX Currency field.

```javascript
var grCurr = new GlideRecord('my_FXCurrency_table');
var curr_field = grCurr.getElement('currency');
var ed = curr_field.getED();
var cur_config = new sn_currency.GlideCurrencyConfig(ed);
var curr_agg_source = cur_config.getAggregationSource();
```

**GlideCurrencyConfig - getConversionDateSource()**

Returns the field used as the source of the date and time for the currency conversion.

If called on an existing FX Currency field that has a corresponding FX Currency Configuration [fx_configuration] record, returns the value of the Conversion Date Source (conversion_date_source) field. Otherwise, if a new record, returns "null".

For more information on the Conversion Date Source field, see Identify the rate table and date source for currency conversions.
### GlideCurrencyConfig - getConversionDateSource()

Returns the number of digits to display for an FX Currency field.

If called on an existing FX Currency field that has a corresponding FX Currency Configuration \([fx\_configuration]\) record, returns the value of the Display Digits (display_digits) field. Otherwise, if a new record, returns a default value.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var grCurr = new GlideRecord('my_FXCurrency_table');
var curr_field = grCurr.getElement('currency');
var ed = curr_field.getED();
var cur_config = new sn_currency.GlideCurrencyConfig(ed);
var curr_conv_date_src = cur_config.getConversionDateSource();
```
## GlideCurrencyConfig

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of digits to display for the FX Currency field. The returned value depends on the constructor used to instantiate the object.</td>
</tr>
<tr>
<td></td>
<td>• GlideCurrencyConfig(Object ed): If an fx_configuration record exists, returns the value of the display_digits field in the FX Currency Configuration [fx_configuration] record that is associated with the FX Currency field specified by the GlideElementDescriptor passed in the constructor. If no fx_configuration record, follows the GlideCurrencyConfig() rules.</td>
</tr>
<tr>
<td></td>
<td>• GlideCurrencyConfig(): If set, returns the value of the glide.currency2.display_digits property in system properties. Otherwise, returns -1.</td>
</tr>
</tbody>
</table>

This code example returns the default number of display digits.

```javascript
var cur_config = new sn_currency.GlideCurrencyConfig();
var curr_display_digits = cur_config.getDisplayDigits();
```

This code example returns the display digits for a specific FX Currency field.

```javascript
var grCurr = new GlideRecord('my_FXCurrency_table');
var curr_field = grCurr.getElement('currency');
var ed = curr_field.getED();
var cur_config = new sn_currency.GlideCurrencyConfig(ed);
var curr_display_digits = cur_config.getDisplayDigits();
```

### GlideCurrencyConfig - getDisplayValue()

Returns the currency code used to convert the FX Currency value when it appears in lists and reports.

If called on an existing FX Currency field that has a corresponding FX Currency Configuration [fx_configuration] record, returns the value of the Display Value Currency (display_value) field. Otherwise, if a new record, returns a default value.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Currency code to use to display the FX Currency field. The returned value depends on the constructor used to instantiate the object.</td>
</tr>
<tr>
<td></td>
<td>• GlideCurrencyConfig(Object ed): If an fx_configuration record exists, returns the display_value field, which contains the currency code, from the fx_configuration record that is associated with the FX Currency field specified by the GlideElementDescriptor passed in the constructor. If no fx_configuration record, follows the GlideCurrencyConfig() rules.</td>
</tr>
<tr>
<td></td>
<td>• GlideCurrencyConfig(): If set, returns the value of the glide.currency2.display_value property in system properties. Otherwise, returns as_entered.</td>
</tr>
</tbody>
</table>

Possible values:

• default: Global default. This is the value in the glide.currency2.display_digits property.
• as_entered: Currency value as entered by the user.
• in_session_currency: Currency value converted to the session currency. Session currency is based on the user's locale.
• in_reference_currency: Reference value if computed and stored. Otherwise, the currency value converted to the reference currency.

This code example returns the default currency code.

```javascript
var cur_config = new sn_currency.GlideCurrencyConfig();
var curr_display_value = cur_config.getDisplayValue();
```

This code example returns the display currency code for a specific FX Currency field.

```javascript
var grCurr = new GlideRecord('my_FXCurrency_table');
var curr_field = grCurr.getElement('currency');
var ed = curr_field.getED();
var cur_config = new sn_currency.GlideCurrencyConfig(ed);
var curr_display_value = cur_config.getDisplayValue();
```

### GlideCurrencyConfig - getRateFilterRateTableField()

Returns the rate table field used as a rate table filter for an FX Currency field.
If called on an existing FX Currency field that has a corresponding FX Currency Configuration \([fx\_configuration]\) record, returns the value of the Rate Table Field \(rate\_filter\_rate\_table\_field\). Otherwise, if a new record, returns a default value.

For more information on rate table filters, see Select the rate and target table fields used for filtering.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Field in the rate table used to filter the rate table records. The returned value depends on the constructor used to instantiate the object.</td>
</tr>
</tbody>
</table>

- GlideCurrencyConfig(Object ed): If an \(fx\_configuration\) record exists, returns the \(rate\_filter\_rate\_table\_field\) from the \(fx\_configuration\) record that is associated with the FX Currency field specified by the GlideElementDescriptor passed in the constructor. If no \(fx\_configuration\) record, follows the GlideCurrencyConfig() rules.

- GlideCurrencyConfig(): Returns null.

This code example returns the rate table field used to filter rate table records for a specific FX Currency field.

```javascript
var grCurr = new GlideRecord('my_FXurrency_table');
var curr_field = grCurr.getElement('currency');
var ed = curr_field.getED();
var cur_config = new sn_currency.GlideCurrencyConfig(ed);
var curr_reference_currency = cur_config.getRateFilterRateTableField();
```

**GlideCurrencyConfig - getRateFilterTargetTableField()**

Returns the target table field used to filter the rate table records for an FX Currency field.

If called on an existing FX Currency field that has a corresponding FX Currency Configuration \([fx\_configuration]\) record, returns the value of the Target Table Field \(rate\_filter\_target\_table\_field\). Otherwise, if a new record, returns a default value.
For more information on rate table filters, see Select the rate and target table fields used for filtering.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Field in the target table used/to use to filter the rate table. The returned value depends on the constructor used to instantiate the object.</td>
</tr>
<tr>
<td></td>
<td>• GlideCurrencyConfig(Object ed): If an fx_configuration record exists, returns the rate_filter_target_table_field from the fx_configuration record that is associated with the FX Currency field specified by the GlideElementDescriptor passed in the constructor. If no fx_configuration record, follows the GlideCurrencyConfig() rules.</td>
</tr>
<tr>
<td></td>
<td>• GlideCurrencyConfig(): Returns null.</td>
</tr>
</tbody>
</table>

This code example returns the default rate filter, target table field.

```javascript
var cur_config = new sn_currency.GlideCurrencyConfig();
var curr_rate_filter = cur_config.getRateFilterTargetTableField();
```

This code example returns the rate filter, target table field for a specific FX Currency field.

```javascript
var grCurr = new GlideRecord('my_FXCurrency_table');
var curr_field = grCurr.getElement('currency');
var ed = curr_field.getED();
var cur_config = new sn_currency.GlideCurrencyConfig(ed);
var curr_rate_filter = cur_config.getRateFilterTargetTableField();
```

**GlideCurrencyConfig - getRateTable()**

Returns the rate table used to convert currency for an FX Currency field.

If called on an existing FX Currency field that has a corresponding FX Currency Configuration [fx_configuration] record, returns the value of the Rate Table Field (rate_filter_rate_table_field). Otherwise, if a new record, returns a default value.
For more information on FX Currency rate tables, see Identify the rate table and date source for currency conversions.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of the rate table used to perform the currency conversion. The returned value depends on the constructor used to instantiate the object.</td>
</tr>
<tr>
<td></td>
<td>• GlideCurrencyConfig(Object ed): If an fx_configuration record exists, returns the rate_table_field field from the fx_configuration record that is associated with the FX Currency field specified by the GlideElementDescriptor passed in the constructor. If no fx_configuration record, follows the GlideCurrencyConfig() rules.</td>
</tr>
<tr>
<td></td>
<td>• GlideCurrencyConfig(): If set, returns the value of the glide.currency2.system_rate_table property from system properties. Otherwise, returns fx_system_rate.</td>
</tr>
</tbody>
</table>

Returns the default rate table.

```
var cur_config = new sn_currency.GlideCurrencyConfig();
var curr_rate_table = cur_config.getRateTable();
```

Returns the rate table used for a specific FX Currency field.

```
var grCurr = new GlideRecord('my_FXCurrency_table');
var curr_field = grCurr.getElement('currency');
var ed = curr_field.getED();
var cur_config = new sn_currency.GlideCurrencyConfig(ed);
var curr_rate_table = cur_config.getRateTable();
```

**GlideCurrencyConfig - getReferenceCurrency()**

Returns the reference currency for an FX Currency field.

If called on an existing FX Currency field that has a corresponding FX Currency Configuration [fx_configuration] record, returns the value of the Reference
Currency (reference_currency) field. Otherwise, if a new record, returns a default value.

For more information on reference currency, see Set the reference currency.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Reference currency as an ISO currency code. The returned value depends on the constructor used to instantiate the object.</td>
</tr>
</tbody>
</table>

- GlideCurrencyConfig(Object ed): If an fx_configuration record exists, returns the reference_currency field from the fx_configuration record that is associated with the FX Currency field specified by the GlideElementDescriptor passed in the constructor. If no fx_configuration record, follows the GlideCurrencyConfig() rules.

- GlideCurrencyConfig(): If set, returns the value of the glide.currency2.default_reference_currency system property. Otherwise the method applies the following rules, in the specified order, to determine the reference currency code:
  - If the glide.system.reference_currency system property is set to true, uses the value in the glide.system.reference_currency.code system property.
  - The value in the glide.system.locale system property (which implies a currency).
  - Default locale of the Java Virtual Machine on which the instance is running.

This code example returns the default reference currency.

```javascript
var cur_config = new sn_currency.GlideCurrencyConfig();
var curr_reference_currency = cur_config.getReferenceCurrency();
```

This code example returns the reference currency for a specific FX Currency field.

```javascript
var grCurr = new GlideRecord('my_FXCurrency_table');
var curr_field = grCurr.getField('currency');
```
```javascript
var ed = curr_field.getED();
var cur_config = new sn_currency.GlideCurrencyConfig(ed);
var curr_reference_currency = cur_config.getReferenceCurrency();
```

**GlideCurrencyConfig - getReferenceCurrencySource()**

Returns the reference currency source for an FX Currency field.

If called on an existing FX Currency field that has a corresponding FX Currency Configuration [fx_configuration] record, returns the value (dot-walk path) of the Reference Currency Source (reference_currency_source) field. Otherwise, if a new record, returns a default value.

For more information on reference currency source, see Set the reference currency.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td>None</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Dot-walk path of the field used/to use as the reference currency. The returned value depends on the constructor used to instantiate the object.</td>
</tr>
</tbody>
</table>

- GlideCurrencyConfig(Object ed): If an fx_configuration record exists, returns the reference_currency_source field from the fx_configuration record that is associated with the FX Currency field specified by the GlideElementDescriptor passed in the constructor. If no fx_configuration record, follows the GlideCurrencyConfig() rules.
- GlideCurrencyConfig(): Returns null.

This code example returns the default reference currency source.

```javascript
var cur_config = new sn_currency.GlideCurrencyConfig();
var curr_reference_currency = cur_config.getReferenceCurrency();
```

This code example returns the reference currency source for a specific FX Currency field.
var grCurr = new GlideRecord('my_FXCurrency_table');
var curr_field = grCurr.getElement('currency');
var ed = curr_field.getED();
var cur_config = new sn_currency.GlideCurrencyConfig(ed);
var curr_reference_currency = cur_config.getReferenceCurrencySource();

GlideCurrencyConfig - GlideCurrencyConfig()

Instantiates a GlideCurrencyConfig object that enables the retrieval of global default FX Currency configuration information.

When calling the available methods on this type of GlideCurrencyConfig object, the return values are the FX Currency global defaults from system properties. If a global default is not defined in system properties, a hard-coded default is returned (this can also be an empty value if not configured). This object does not provide configuration information for a specific FX Currency field. To retrieve specific FX Currency field information, use the GlideCurrencyConfig - GlideCurrencyConfig(Object ed) constructor.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var cur_config = new sn_currency.GlideCurrencyConfig();
```

GlideCurrencyConfig - GlideCurrencyConfig(Object ed)

Instantiates a GlideCurrencyConfig object that enables the retrieval of the configuration information for a specific FX Currency field.

When calling the available methods on this type of GlideCurrencyConfig object, the return values are from the FX Currency Configuration [fx_configuration] record associated with the FX Currency field, if a record exists. If a record does not exist, default values are returned.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ed</td>
<td>GlideElementDescriptor</td>
<td>GlideElementDescriptor object of the FX Currency field to associate with the GlideCurrencyConfig object.</td>
</tr>
</tbody>
</table>

Example

```javascript
var grCurr = new GlideRecord('my_FXCurrency_table');
var curr_field = grCurr.getElement('currency');
var ed = curr_field.getED();
var cur_config = new sn_currency.GlideCurrencyConfig(ed);
```

**GlideCurrencyConverter - Scoped**

The GlideCurrencyConverter API provides methods to convert one currency value to another, such as converting US dollars into European Euro.

You can instantiate the GlideCurrencyConverter object and define the source and destination currencies during instantiation using GlideCurrencyConverter(from, to). You can also instantiate the object without these values and define them later using the setFromCurrency() and setToCurrency() methods. These values and the amount to convert must be set before calling the convert() method to perform the currency conversion. To set the amount to convert, use the setAmount() method.

The GlideCurrencyConverter() API also provides optional methods that enable you to:

- Set the date and time for which to perform the conversion, setDateTime(). By setting the date and time, the rate that is used in the conversion calculation is that for the specified date and time, instead of the default of the current date and time.

- Set the rate table to use in the conversion, setRateTable(). By default the conversion uses the fx_system_rate table however, you can define custom rate tables for your instance. For additional information on creating rate tables, see Add conversion rates using a custom rate table.

This class runs in the sn_currency namespace.

**Scoped GlideCurrencyConverter - convert()**

Executes the currency converter.
Call this method after calling other GlideCurrencyConverter methods that construct the currency conversion, such as setAmount(), setRateTable(), and setDate().

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>If the conversion is successful, returns CurrencyExchangeValue object. If unsuccessful, returns &quot;null&quot;.</td>
</tr>
</tbody>
</table>

```javascript
CurrencyExchangeValue {
  Rate: Number,
  OriginalAmount: Number,
  Amount: Number,
  fromCurrency: String,
  toCurrency: String,
  rateSysId: String
}
```

- **Rate**: Number. Exchange rate used in the conversion.
- **OriginalAmount**: Number. Source currency amount.
- **Amount**: Number. Converted amount (OriginalAmount * Rate).
- **fromCurrency**: String. Three-letter ISO 3166 country code of the source currency.
- **toCurrency**: String. Three-letter ISO 3166 country code of the converted currency.
- **rateSysId**: String. Sys_id of the rate table record used to calculate the conversion.

Example

```javascript
var conv = new sn_currency.GlideCurrencyConverter('EUR', 'USD');
conv.setAmount(100);
gs.info(conv.convert());
```

Output:
CurrencyExchangeValue{Rate = 1.0777, OriginalAmount = 100, Amount = 107.7700, fromCurrency = 'EUR', toCurrency = 'USD', rateSysId = '2ed537fcb271937adb'}

Scoped GlideCurrencyConverter - GlideCurrencyConverter()
Instantiates a GlideCurrencyConverter object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example

```java
var conv = new sn_currency.GlideCurrencyConverter();
```

Scoped GlideCurrencyConverter - GlideCurrencyConverter(String from, String to)
Instantiates a GlideCurrencyConverter object and sets the source and destination country codes to use in the currency conversion.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>from</td>
<td>String</td>
<td>Three-letter ISO 3166 country code of the source currency.</td>
</tr>
<tr>
<td>to</td>
<td>String</td>
<td>Three-letter ISO 3166 country code of the converted currency.</td>
</tr>
</tbody>
</table>

Example

```java
var conv = new sn_currency.GlideCurrencyConverter('EUR', 'USD');
```

Scoped GlideCurrencyConverter - setAmount(String amount)
Sets the amount of currency to convert.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>amount</td>
<td>String</td>
<td>Currency amount to convert. This value must be unformatted except for a decimal point to denote fractional currency. For example, 1234.56 is valid, 1,234.56 is invalid.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var conv = new sn_currency.GlideCurrencyConverter('EUR', 'USD');
conv.setAmount(100);
```

 Scoped GlideCurrencyConverter - setDateTime(Object date)

Sets the currency conversion date and time.

This date and time determines the conversion rate that is used to convert the currency. If this method is not called before the GlideCurrencyConverter.convert() method, the conversion is performed using the rate for the current date/time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>GlideDateTime</td>
<td>Date/time for which to calculate the currency conversion. This value determines the rate that is used in the conversion.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example
var conv = new sn_currency.GlideCurrencyConverter('EUR', 'USD');
conv.setAmount(100);
var gd = new GlideDateTime("2019-01-03 11:00:00");
conv.setDateTime(gd);
gs.info(conv.convert());

Output:

```
CurrencyExchangeValue{fOriginalAmount=100, fOriginalCurrency='EUR', fRate=1.061,
  fAmount=106.1, fCurrency='USD', fRateSysId='4555525f5553445f31303030313031'}
```

**Scoped GlideCurrencyConverter - setFromCurrency(String from)**

Sets the country code of the source currency.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>from</td>
<td>String</td>
<td>Three-letter ISO 3166 country code of the source currency.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

```
var conv = new sn_currency.GlideCurrencyConverter().setFromCurrency('FRA');
```

**Scoped GlideCurrencyConverter - setRateTable(String rateTable)**

Defines the rate table to use in the currency conversion.

If this method is not called before the GlideCurrencyConverter.convert() method is called, the conversion is performed using the fx_system_rate table. All custom rate tables must extend the fx_conversion_rate table. For additional information on creating rate tables, see Add conversion rates using a custom rate table.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rateTable</td>
<td>String</td>
<td>Name of the rate table to use in the currency conversion.</td>
</tr>
</tbody>
</table>
**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

```javascript
var conv = new sn_currency.GlideCurrencyConverter('EUR', 'USD');
conv.setRateTable(custom_rate_table);
```

**Scoped GlideCurrencyConverter - setToCurrency(String to)**

Sets the country code of the destination currency.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>to</td>
<td>String</td>
<td>Three-letter ISO 3166 country code of the source currency.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

```javascript
var conv = new sn_currency.GlideCurrencyConverter().setToCurrency('USA');
```

**GlideCurrencyExchangeValue - Scoped**

Provides access to information related to FX Currency conversions.

Refer to the GlideCurrencyConverter() API for methods that return a GlideCurrencyExchangeValue object.

**Note:** There is no constructor for this class.

**Scoped GlideCurrencyExchangeValue - getAmount()**

Returns the currency amount after the conversion.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td></td>
<td>Currency amount after the conversion.</td>
</tr>
</tbody>
</table>

This example assumes a conversion rate of 1 Euro = 0.92 US dollars.

```javascript
var conv = new sn_currency.GlideCurrencyConverter('EUR', 'USD');
conv.setAmount(100);
var convertValues = conv.convert();
gs.info('Exchanged Amount: ' + convertValues.getAmount());
```

Output:

```
Exchanged Amount: $92.00
```

### Scoped GlideCurrencyExchangeValue - `getCurrency()`

Returns the converted to currency type.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td></td>
<td>Three-letter ISO currency code of the converted to currency.</td>
</tr>
</tbody>
</table>

Example

```javascript
var convertValues = new sn_currency.GlideCurrencyConverter('USD', 'JPY');
convertValues.setAmount(100);
gs.info('Exchanged Currency (To): ' + convertValues.convert().getCurrency());
```

Output:
Exchanged Currency (To): JPY

Scoped GlideCurrencyExchangeValue - getOriginalCurrency()
Returns the original, pre-conversion currency type.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Three-letter ISO currency code of the currency converted from.</td>
</tr>
</tbody>
</table>

Example

```javascript
var converter = new sn_currency.GlideCurrencyConverter('USD', 'JPY');
converter.setAmount(999.999)
var convertValues = converter.convert();
gs.info('Original Amount: ' + convertValues.getOriginalCurrency());
```

Output:

Original Amount: USD

Scoped GlideCurrencyExchangeValue - getOriginalValue()
Returns the original, pre-conversion amount.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Original amount before conversion.</td>
</tr>
</tbody>
</table>
Example

```javascript
var converter = new sn_currency.GlideCurrencyConverter('USD', 'JPY');
converter.setAmount(999.999)
var convertValues = converter.convert();
gs.info('Original Amount: ' + convertValues.getOriginalAmount());
```

Output:

Original Amount: 999.999

Scoped GlideCurrencyExchangeValue - getRate()
Returns the exchange rate used during the conversion.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Exchange rate used in the currency conversion.</td>
</tr>
</tbody>
</table>

Example

```javascript
var converter = new sn_currency.GlideCurrencyConverter('EUR', 'USD');
converter.setAmount(999.999)
var convertValues = converter.convert();
gs.info('Original Amount: ' + convertValues.getRate());
```

Output:

Exchange rate: 1.0559

Scoped GlideCurrencyExchangeValue - getRateSysId()
Returns the sys_id of the record in the rate table used in the currency conversion.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the rate table used in the currency conversion.</td>
</tr>
</tbody>
</table>

Example

```javascript
var converter = new sn_currency.GlideCurrencyConverter('USD', 'JPY');
converter.setAmount(999.999);
var convertValues = converter.convert();
gs.info('Rate table sys_id: ' + convertValues.getRateSysId());
```

Output:

Original Amount: 99ebb4156fa831005be8883e6b3ee4b9

**GlideCurrencyFormatter - Scoped**

The GlideCurrencyFormatter API provides methods to format FX Currency strings.

When instantiating the GlideCurrencyFormatter object, you define the format of the output results for this object. Once set, the same format is used each time you call the GlideCurrencyFormatter.format() method of that object. The GlideCurrencyFormatter() and format() methods are the only two methods that you must call to format FX Currency.

The GlideCurrencyFormatter() API also provides optional methods that enable you to:

- Set the locale of the currency using setLocale(). By setting the locale, the formatter takes into consideration any formatting that is specific to that locale, such as whether a decimal point or decimal comma is used to denote fractions of currency amount. Default: System locale

- Set the minimum number of fractional digits to display using setMinFractionDigits(). Defines the minimum number of digits to the right of the decimal point/decimal comma to include. By default, all digits passed in are displayed. If the passed in amount has fewer digits than the specified minimum, the result is padded with "0".

- Set the maximum number of fractional digits to display using setMaxFractionDigits(). Defines the maximum number of digits to the right of the decimal point/decimal comma to include. By default, all digits passed in are displayed. If the passed in amount has a greater number of digits than the specified maximum, the additional digits are truncated during the process of rounding to the number of maximum fraction digits. Rounding is performed to the closest right-most digit. For example, if the maximum fraction digit is set to
2 and the passed in currency value is 123.456, the formatted value is 123.46. If the currency value is 23.122, the formatted value is 23.12. If the maximum is set to less than the minimum, the minimum value is used.

This class runs in the `sn_currency` namespace.

**Scoped GlideCurrencyFormatter - GlideCurrencyFormatter(String formatString)**

Instantiates a GlideCurrencyFormatter object and defines the format string to use to format FX Currency.

This method does not perform the actual string format. You must call the `GlideCurrencyFormatter.format()` method to format the currency.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>formatString</td>
<td>String</td>
<td>Optional. Format string to use to format any currency passed into the formatter. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• %s: Replaced by the currency symbol associated with the country code specified in the <code>format()</code> call.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• %v: Replaced by the currency amount, such as 123.45.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• %c: Replaced by the ISO currency code specified in the <code>format()</code> call, such as USD or EUR.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• %l: Replaced with the passed in value, no formatting performed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• %p: Replaced by the percent sign (%).</td>
</tr>
</tbody>
</table>

For example, if the format string is `%s%v%c` and the value to format is 123.45 in US dollars, the returned formatted string is $123.45 USD. If the format string is `%s%l%c` and the value string to format is '56M' in Euros, the returned formatted string is €56M EUR.

**Note:** The same format string is used each time the `format()` method is called on this object.
var formatString = '%s%v%c';
var exchangeValue = new sn_currency.GlideCurrencyFormatter(formatString);

Scoped GlideCurrencyFormatter - format(String value, String currencyCode)
Formats a specified currency value using the specified currency code.

The resulting format of the currency is also dependent on the values passed in when the GlideCurrencyFormatter object was initially instantiated.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>Currency amount to format. The amount can only contain a decimal point to denote the fractional amount, commas are not supported. Valid values: 123.45 or 2436.23 Invalid values 123,45 or 2,134.56</td>
</tr>
<tr>
<td>currencyCode</td>
<td>String</td>
<td>Three-letter ISO currency code to use when formatting the currency.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Formatted currency value.</td>
</tr>
</tbody>
</table>

Example

```javascript
var amount = '123456.123456789';
var currencyCode = 'USD';
var formatString = '%s%v%c';
var exchangeValue = new sn_currency.GlideCurrencyFormatter(formatString);
gs.info('Formatted currency: ' + exchangeValue.setMaxFractionDigits(2).format(amount, currencyCode));
```

Output:

Formatted currency: $123,456.12USD
Scoped GlideCurrencyFormatter - setLocale(String language, String country)

Sets the default language and country, which constitutes the locale, for the currency formatter.

If you do not call this method before calling the GlideCurrencyFormatter.format() method, the locale defaults to the current session locale.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>language</td>
<td>String</td>
<td>Two-letter ISO 639 language code, such as en, sp, and fr.</td>
</tr>
<tr>
<td>country</td>
<td>String</td>
<td>Two-letter ISO 3166 country code, such as US, ES, and FR.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows setting the currency formatter to France.

```javascript
var amount = '123456.123456789';
var currencyCode = 'EUR';
var formatString = '%s%v%c';
var exchangeValue = new sn_currency.GlideCurrencyFormatter(formatString);
exchangeValue.setLocale("fr", "FR"); // Language = fr Country = FR
gs.info('Formatted currency: ' + exchangeValue.setMaxFractionDigits(2).format(amount, currencyCode));
```

Output:

Formatted currency: €123 456,12EUR

Scoped GlideCurrencyFormatter - setMaxFractionDigits(Number maxFractionDigits)

Sets the maximum number of digits to the right of the decimal point/decimal comma to return.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxFractionDigits</td>
<td>Number</td>
<td>Maximum number of fraction digits to return. If this value is set to something less than the minFractionDigits value, it is overridden by minFractionDigits.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var amount = '123456.123456789';
var currencyCode = 'USD';
var formatString = '%s%v%c';
var exchangeValue = new sn_currency.GlideCurrencyFormatter(formatString);
gs.info('Formatted currency: ' + exchangeValue.setMaxFractionDigits(2).format(amount, currencyCode));
```

Output:

Formatted currency: $123,456.12USD

Scoped GlideCurrencyFormatter - setMinFractionDigits(Number minFractionDigits)

Sets the minimum number of fraction digits (right of the decimal point/decimal comma) to return.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>minFractionDigits</td>
<td>Number</td>
<td>Minimum number of fraction digits to return.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var amount = '123456.12';
var currencyCode = 'USD';
var formatString = '%s%v%c';
var exchangeValue = new sn_currency.GlideCurrencyFormatter(formatString);
gs.info('Formatted currency: ' + exchangeValue.setMinFractionDigits(3).format(amount, currencyCode));

Output:
Formatted currency: $123,456.120USD

GlideCurrencyParser - Scoped
The GlideCurrencyParser API provides methods to parse FX Currency values to detect locale-based formatting.

The methods in this class parse a specified string into a GlideCurrencyValue object enabling you to obtain locale-based currency formatting. Before calling the GlideCurrencyParser.parse() method, which actually performs the parse, you must set the currency code to use during the parse. You can set the currency code by either passing it in the GlideCurrencyParser.parse() method call or by calling GlideCurrencyParser.setDefaultCurrencyCode().

Setting the locale is optional. If you do not set it through the GlideCurrencyParser.setLocale() method, the currency amount passed into GlideCurrencyParser.parse() must be unformatted.

This class runs in the sn_currency namespace.

Scoped GlideCurrencyParser - GlideCurrencyParser()
Instantiates a GlideCurrencyParser object that provides methods to parse a string into a GlideCurrencyValue object.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

Example
var parser = new sn_currency.GlideCurrencyParser();
Scoped GlideCurrencyParser - parse(String value)

Parses a specified string into a GlideCurrencyValue object to obtain locale-based currency formatting.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| value | String| String to parse. You can prepend this string with the ISO currency code to use when parsing the string (semicolon separated). If the currency code is not set prior to calling the parse() method, it defaults to the current session currency code. This method supports both decimal point and decimal comma notation. For example: "123.45", "USD;123.45", "123.45", "EUR;123.45"

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideCurrencyValue</td>
<td>Parsed value information. Data type: Object</td>
</tr>
</tbody>
</table>

Passes the currency code in value string.

```javascript
var gp = new sn_currency.GlideCurrencyParser();
gp.setLocale("fre", "FRA");
var cv = gp.parse("USD;1234.56");
gs.info(cv);
```

Output:

USD;1234.56

Uses the setDefaultCurrencyCode property to define currency code.

```javascript
var amount = "1234,56"
var gp = new sn_currency.GlideCurrencyParser();
gp.setDefaultCurrencyCode("USD");
var cv = gp.parse(amount);
gs.info(cv);
```

Output:

USD;1234.56
Scoped GlideCurrencyParser - setDefaultCurrencyCode(String currencyCode)
Sets the currency code for the associated GlideCurrencyParser object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>currencyCode</td>
<td>String</td>
<td>Three-letter ISO currency code to use as the default in the associated GlideCurrencyParser object.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var amount = “123.45”
var gp = new sn_currency.GlideCurrencyParser();
    gp.setDefaultCurrencyCode("USD");
var cv = gp.parse(amount);
```

Scoped GlideCurrencyParser - setLocale(String language, String country)
Sets the default language and country codes, which constitute the locale, on the associated GlideCurrencyParser object.

If you do not call this method before calling the GlideCurrencyParser.parse() method, the locale defaults to the current session locale.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>language</td>
<td>String</td>
<td>Three-letter ISO 639 language code, such as eng, spa, and fre.</td>
</tr>
<tr>
<td>country</td>
<td>String</td>
<td>Three-letter ISO 3166 country code, such as USA, ESP, and FRA.</td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>void</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Example**

```javascript
var amount = "USD;123.45"
var gp = new sn_currency.GlideCurrencyParser();
gp.setLocale("spa", "ESP");
var cv = gp.parse(amount);
```

**GlideCurrencyValue - Scoped**

Provides methods that return the currency code and original currency from an associated GlideCurrencyParser.parse() call.

ℹ️ **Note:** There is no constructor for this class.

**Scoped GlideCurrencyValue - getAmount()**

Returns the currency amount originally passed into the associated GlideCurrencyParser.parse() call.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Original currency passed into the parse() method.</td>
</tr>
</tbody>
</table>

**Example**

```javascript
var gp = new sn_currency.GlideCurrencyParser();
gp.setLocale("eng", "USA");
var cv = gp.parse("USD;1234.56");
gs.info('Original currency amount: ' + cv.getAmount());
```

**Output:**
Original currency amount: 1234.56

 Scoped GlideCurrencyValue - getCurrencyCode()
 Returns the currency code used to parse the currency in the associated GlideCurrencyParser.parse() call.

 Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

 Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Three-letter ISO currency code used to parse the currency.</td>
</tr>
</tbody>
</table>

 Example

 ```javascript
 var gp = new sn_currency.GlideCurrencyParser();
gp.setLocale(eng, USA);
var cv = gp.parse("USD";"1234.56");
gs.info('Parsed currency code: ' + cv.getCurrencyCode());
```

 Output:  
 Parsed currency code: USD

 GlideDate - Scoped
 The scoped GlideDate class provides methods for performing operations on GlideDate objects, such as instantiating GlideDate objects or working with GlideDate fields.

 Scoped GlideDate - getByFormat(String format)
 Gets the date in the specified date format.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>String</td>
<td>Desired date format using Java <code>SimpleDateFormat</code>. For example, &quot;dd-MM-yyyy&quot; to get the day, month, and year, or &quot;EEEE&quot; to get the day of the week.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Date value for the GlideDate object in the specified format.</td>
</tr>
</tbody>
</table>

```javascript
var gd = new GlideDate();
gd.setValue('2021-04-21');
gs.info(gd.getByFormat("dd-MM-yyyy"));
```

Output:

```
21-04-2021
```

### Scoped GlideDate - getDayOfMonthNoTZ()

Gets the day of the month stored by the GlideDate object, expressed in the UTC time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The day of the month in the UTC time zone, from 1 to 31.</td>
</tr>
</tbody>
</table>

```javascript
// Today's date is 2016-05-13
var gd = new GlideDate();
gs.info(gd.getDayOfMonthNoTZ());
```

Output: 13
Scoped GlideDate - getDisplayValue()

 Gets the date in the current user's display format and time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Date value for the GlideDate object in the current user's display format and time zone. Keep in mind when designing business rules or script includes that this method may return values in different formats for different users.</td>
</tr>
</tbody>
</table>

```javascript
var gd = new GlideDate();
gd.setValue('2021-04-21');
gs.info(gd.getDisplayValue());
```

Output:

```
2021-04-21
```

Scoped GlideDate - getDisplayValueInternal()

 Gets the date in the internal format (yyyy-MM-dd) and current user's timezone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Date value for the GlideDate object in the current user's time zone. Format: yyyy-MM-dd</td>
</tr>
</tbody>
</table>
```javascript
var gd = new GlideDate();
gs.info(gd.getDisplayValueInternal());
```

Output:

2021-04-21

**Scoped GlideDate - getMonthNoTZ()**

Gets the month stored by the GlideDate object, expressed in the UTC time zone.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The numerical value of the month from 1 to 12.</td>
</tr>
</tbody>
</table>

```javascript
//Today's date is 2016-05-13
var gd = new GlideDate();
gs.info(gd.getMonthNoTZ());
```

Output: 5

**Scoped GlideDate - getValue()**

Gets the date in the internal format (yyyy-MM-dd) and the system time zone (UTC by default).

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The date value for the GlideDate object in the system time zone.</td>
</tr>
</tbody>
</table>
### Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Format: yyyy-MM-dd</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gd = new GlideDate();
gd.setValue('2021-04-21');
gs.info(gd.getValue());
```

**Output:**

```
2021-04-21
```

### Scoped GlideDate - getYearNoTZ()

 Gets the year stored by the GlideDate object, expressed in the UTC time zone.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The numerical value of the year.</td>
</tr>
</tbody>
</table>

```javascript
//Today's date is 2016-05-13
var gd = new GlideDate();
gs.info(gd.getYearNoTZ());
```

**Output:** 2016

### Scoped GlideDate - GlideDate()

 Creates a GlideDate object with the current date time.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
//Today's date is April 21, 2021
var gd = new GlideDate();
gs.info(gd.getValue());

Output:
2021-04-21

**Scoped GlideDate - setDisplayValue(String asDisplayed)**
Sets a date value using the current user's display format and time zone.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asDisplayed</td>
<td>String</td>
<td>Date in the current user's display format and time zone. Format: Must be formatted using the current user's preferred display format, such as yyyy-MM-dd.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gd = new GlideDate();
gd.setDisplayValue("2011-01-01");
gs.info(gd.getValue());

Output: 2011-01-01

**Scoped GlideDate - setValue(String o)**
Sets the date of the current GlideDate object in internal format (yyyy-MM-dd) and the system time zone (UTC by default).

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>o</td>
<td>String</td>
<td>Date and time to set in the current GlideDate object. Format: yyyy-MM-dd</td>
</tr>
</tbody>
</table>
 Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gd = new GlideDate();
gd.setValue('2015-01-01');
gs.info(gd.getValue());
```

Output: 2015-01-01

Scoped GlideDate - subtract(GlideDate start, GlideDate end)

Gets the duration difference between two GlideDate values.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>GlideDate</td>
<td>The start value.</td>
</tr>
<tr>
<td>end</td>
<td>GlideDate</td>
<td>The end value.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDuration</td>
<td>The duration between the two values.</td>
</tr>
</tbody>
</table>

```javascript
var sgd1 = new GlideDate();
sgd1.setDisplayValue('2014-07-18');
var sgd2 = new GlideDate();
sgd2.setDisplayValue('2014-07-19');

var duration = GlideDate.subtract(sgd1, sgd2);
gs.info(duration.getDisplayValue());
```

Output:

1 Day
GlideDateTime - Global

The GlideDateTime class provides methods for performing operations on GlideDateTime objects, such as instantiating GlideDateTime objects or working with glide_date_time fields.

Use the GlideDateTime methods to perform date-time operations, such as instantiating a GlideDateTime object, performing date-time calculations, formatting a date-time, or converting between date-time formats.

GlideDateTime - add(Number milliseconds)

Adds a specified number of milliseconds to the GlideDateTime object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>The number of milliseconds to add</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getNumericValue());
gdt.add(10);
gs.print(gdt.getNumericValue());
```

Output:

```
1314777600000
1314777600010
```

Scoped equivalent

To use the add() method in a scoped application, use the corresponding scoped method: Scoped GlideDateTime - add(Number milliseconds).

GlideDateTime - add(GlideTime time)

Adds a GlideTime object to the current GlideDateTime object.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>GlideTime</td>
<td>GlideTime object whose time value to add to the specified GlideDateTime object.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to add 20 seconds to the time set in the gdt GlideDateTime object.

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
var gtime1 = new GlideTime();
gtime1.setValue("00:00:20");
gdt.add(gtime1);
gs.print(gdt.toString());
```

Output:

```
2011-08-31 08:00:20
```

### Scoped equivalent

To use the `add()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - add(GlideTime gd)**.

**GlideDateTime - addDays(Number days)**

Adds a specified number of days to the current GlideDateTime object. A negative parameter subtracts days.

Use `addDaysLocalTime()` and `addDaysUTC()` instead of this method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>Number</td>
<td>The number of days to add. Use a negative number to subtract.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addDays(-1);
gs.print(gdt.getDate());
```

Output: 2011-08-30

**GlideDateTime - addDaysLocalTime(Number days)**

Adds a specified number of days to the current GlideDateTime object. A negative parameter subtracts days.

The method determines the local date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts days using the local date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>Number</td>
<td>The number of days to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addDaysLocalTime(-1);
gs.print(gdt.getLocalDate());
```

Output: 2011-08-30

**Scoped equivalent**

To use the `addDaysLocalTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - addDaysLocalTime(Number days)`. 
GlideDateTime - addDaysUTC(Number days)

Adds a specified number of days to the current GlideDateTime object. A negative parameter subtracts days.

The method determines the UTC date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts days using the UTC date and time values.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>Number</td>
<td>The number of days to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addDaysUTC(-1); gs.print(gdt.getDate());
```

Output: 2011-08-30

**Scoped equivalent**

To use the `addDaysUTC()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - addDaysUTC(Number days)**.

**GlideDateTime - addSeconds(Number seconds)**

Adds a specified number of seconds to the GlideDateTime object.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seconds</td>
<td>Number</td>
<td>The number of seconds to add</td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td>---------</td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>void</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```
var gdt = new GlideDateTime("2011-12-07 08:00:00");
gdt.addSeconds(1000);
gs.print(gdt.getValue());
```

Output: 2011-12-07 08:16:40

**Scoped equivalent**

To use the `addSeconds()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - addSeconds(Number seconds)`.

**GlideDateTime - addWeeks(Number weeks)**

Adds a specified number of weeks to the current GlideDateTime object. A negative parameter subtracts weeks.

Use `addWeeksLocalTime()` and `addWeeksUTC()` instead of this method.

```
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addWeeks(-1);
gs.print(gdt.getDate());
```

Output: 2011-08-24
GlideDateTime - addWeeksLocalTime(Number weeks)

Adds a specified number of weeks to the current GlideDateTime object. A negative parameter subtracts weeks.

The method determines the local date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts weeks using the local date and time values.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>weeks</td>
<td>Number</td>
<td>The number of weeks to add. Use a negative number to subtract.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addWeeksLocalTime(-1);
gs.print(gdt.getDate());
```

Output: 2011-08-24

**Scoped equivalent**

To use the `addWeeksLocalTime()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - addWeeksLocalTime(Number weeks)**.

GlideDateTime - addWeeksUTC(Number weeks)

Adds a specified number of weeks to the current GlideDateTime object. A negative parameter subtracts weeks.

The method determines the UTC date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts weeks using the UTC date and time values.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>weeks</td>
<td>Number</td>
<td>The number of weeks to add. Use a negative number to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addWeeksUTC(-1);
gs.print(gdt.getDate());
```

Output: 2011-08-24

Scoped equivalent

To use the `addWeeksUTC()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - addWeeksUTC(Number weeks)**.

GlideDateTime - addMonths(Number months)

Adds a specified number of months to the current GlideDateTime object. A negative parameter subtracts months.

Use `addMonthsLocalTime()` or `addMonthsUTC()` instead of this method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>The number of months to add. Use a negative number to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addMonths(2);
gs.print(gdt.getDate());

Output: 2011-10-31

GlideDateTime - addMonthsLocalTime(Number months)

Adds a specified number of months to the current GlideDateTime object. A negative parameter subtracts months.

The method determines the local date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts months using the local date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>The number of months to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addMonthsLocalTime(2);
gs.print(gdt.getDate());

Output: 2011-10-31

Scoped equivalent

To use the `addMonthsLocalTime()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - addMonthsLocalTime(Number months)**.

GlideDateTime - addMonthsUTC(Number months)

Adds a specified number of months to the current GlideDateTime object. A negative parameter subtracts months.
The method determines the UTC date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts months using the UTC date and time values.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>The number of months to add. Use a negative number to subtract.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addMonthsUTC(2);
gs.print(gdt.getDate());
```

Output: 2011-10-31

**Scoped equivalent**

To use the `addMonthsUTC()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - addMonthsUTC(Number months)**.

**GlideDateTime - addYears(Number years)**

Adds a specified number of years to the current GlideDateTime object. A negative parameter subtracts years.

Use `addYearsLocalTime()` or `addYearsUTC()` instead of this method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>years</td>
<td>Number</td>
<td>The number of years to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2010-08-31 08:00:00");
gdt.addYears(1);
gs.print(gdt.getDate());
```

Output: 2011-08-31

**GlideDateTime - addYearsLocalTime(Number years)**

Adds a specified number of years to the current GlideDateTime object. A negative parameter subtracts years.

The method determines the local date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts years using the local date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>years</td>
<td>Number</td>
<td>The number of years to add. To subtract use a negative value.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2010-08-31 08:00:00");
gdt.addYearsLocalTime(1);
gs.print(gdt.getDate());
```

Output: 2011-08-31

**Scoped equivalent**

To use the `addYearsLocalTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - addYearsLocalTime(Number years)`.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
GlideDateTime - addYearsUTC(Number years)

Adds a specified number of years to the current GlideDateTime object. A negative parameter subtracts years.

The date and time value stored by GlideDateTime object is interpreted as being in the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>years</td>
<td>Number</td>
<td>The number of years to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2010-08-31 08:00:00");
gdt.addYearsUTC(1);
gs.print(gdt.getDate());
```

Output: 2011-08-31

Scoped equivalent

To use the addYearsUTC() method in a scoped application, use the corresponding scoped method: Scoped GlideDateTime - addYearsUTC(Number years).

GlideDateTime - compareTo(Object dateTime)

Compares two date and time objects to determine whether one occurs before the other or if they are equivalent.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>Object</td>
<td>Date time in a GlideDateTime object</td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>• 0 = Dates are equal</td>
</tr>
<tr>
<td></td>
<td>• 1 = The object's date is after the date specified in the parameter</td>
</tr>
<tr>
<td></td>
<td>• -1 = The object's date is before the date specified in the parameter</td>
</tr>
</tbody>
</table>

```javascript
var initDate = new GlideDateTime("2011-08-01 12:00:00");
var compDate1 = new GlideDateTime("2011-08-01 12:00:00");
var compDate2 = new GlideDateTime("2011-07-31 12:00:00");
var compDate3 = new GlideDateTime("2011-08-04 16:00:00");

gs.info(initDate.compareTo(compDate1)); // Equals (0)
gs.info(initDate.compareTo(compDate2)); // initDate is after compDate2 (1)
gs.info(initDate.compareTo(compDate3)); // initDate is before compDate3 (-1)
```

### Scoped equivalent

To use the `compareTo()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - compareTo(Object o).**

### GlideDateTime - equals(Object GDT)

Compares an object with an existing value for equality.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GDT</td>
<td>Object</td>
<td>The object to compare. Can be a GlideDateTime object or a valid date time string.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if they are equal, false otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 00:00:00");
gs.print(gdt.equals("2011-09-30 00:12:01"));
```

Output: false
Scoped equivalent

To use the `equals()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - equals(Object dateTime)`.

GlideDateTime - `getDate()`

Gets the date stored by the GlideDateTime object, expressed in the standard format, yyyy-MM-dd, and the system time zone, UTC by default.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDate</td>
<td>The date in the system time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getDate());
```

Output: 2011-08-31

Scoped equivalent

To use the `getDate()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getDate()`.

GlideDateTime - `getDayOfMonth()`

Gets the current day of the month in the UTC time zone.

Use `getDayOfMonthLocalTime()` and `getDayOfMonthUTC()` instead of this method.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>--------</td>
<td>------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Number</td>
<td>The day of the month in the UTC time zone, from 1 to 31.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-02 12:00:00");
gs.print(gdt.getDayOfMonth());
```

Output: 2

### GlideDateTime - getDayOfMonthLocalTime()

Gets the day of the month stored by the GlideDateTime object, expressed in the current user's time zone.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The day of the month in the user's time zone, from 1 to 31.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-02 12:00:00");
gs.print(gdt.getDayOfMonthLocalTime());
```

Output: 2

**Scoped equivalent**

To use the `getDayOfMonthLocalTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getDayOfMonthLocalTime()`.

### GlideDateTime - getDayOfMonthUTC()

Gets the day of the month stored by the GlideDateTime object, expressed in the UTC time zone.
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The day of the month in the UTC time zone, from 1 to 31.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-02 12:00:00");
gs.print(gdt.getDayOfMonthUTC());
```

Output: 2

**Scoped equivalent**

To use the `getDayOfMonthUTC()` method in a scoped application, use the corresponding scoped method: Scoped GlideDateTime - `getDayOfMonthUTC()`.

**GlideDateTime - getDayOfWeek()**

Retrieves the day of the week stored by the GlideDateTime object, expressed in the user's time zone.

Use `getDayOfWeekLocalTime()` and `getDayOfWeekUTC()` instead of this method.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The day of the week value - Monday = 1, ... Sunday = 7.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-01 12:00:00");
gs.print(gdt.getDayOfWeek());
```

Output: 4
**GlideDateTime - getDayOfWeekLocalTime()**

Gets the day of the week stored by the GlideDateTime object, expressed in the user's time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The day of the week value - Monday = 1, ... Sunday = 7</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-01 12:00:00");
gs.print(gdt.getDayOfWeekLocalTime());
```

Output: 4

**Scoped equivalent**

To use the `getDayOfWeekLocalTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getDayOfWeekLocalTime()`.

**GlideDateTime - getDayOfWeekUTC()**

Gets the day of the week stored by the GlideDateTime object, expressed in the UTC time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The day of the week value - Monday = 1, ... Sunday = 7</td>
</tr>
</tbody>
</table>

© 2021 ServiceNow, Inc. All rights reserved. ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
var gdt = new GlideDateTime("2011-12-01 12:00:00");
gs.print(gdt.getDayOfWeekUTC());

Output: 4

**Scoped equivalent**

To use the `getDayOfWeekUTC()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getDayOfWeekUTC()`.

**GlideDateTime - getDaysInMonth()**

Gets the number of days in the month stored by the GlideDateTime object, expressed in the Java Virtual Machine time zone.

Use `getDaysInMonthLocalTime()` and `getDaysInMonthUTC()` instead of this method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of days in the current month in the Java Virtual Machine time zone.</td>
</tr>
</tbody>
</table>

```java
var gdt = new GlideDateTime(); //December
gs.print(gdt.getDaysInMonth());
```

Output: 31

**GlideDateTime - getDaysInMonthLocalTime()**

Gets the number of days in the month stored by the GlideDateTime object, expressed in the current user’s time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of days in the current month in the user's time zone.</td>
</tr>
</tbody>
</table>

```
var gdt = new GlideDateTime(); //December
gs.print(gdt.getDaysInMonthLocalTime());
```

Output: 31

Scoped equivalent

To use the `getDaysInMonthLocalTime()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - getDaysInMonthLocalTime().**

GlideDateTime - `getDaysInMonthUTC()`

Gets the number of days in the month stored by the GlideDateTime object, expressed in the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of days in the month stored by the GlideDateTime object, expressed in the UTC time zone.</td>
</tr>
</tbody>
</table>

```
var gdt = new GlideDateTime(); //December
gs.print(gdt.getDaysInMonthUTC());
```

Output: 31

Scoped equivalent

To use the `getDaysInMonthUTC()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - getDaysInMonthUTC().**
GlideDateTime - getDisplayValue()

Gets the date and time value in the current user's display format and time zone.

⚠️ Note: Referring to the GlideDateTime object directly returns the date and time value in the GMT time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Date and time in the user's format and time zone. Keep in mind when designing business rules or script includes that this method may return values in different formats for different users.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getDisplayValue());
```

Output:

```
2011-08-31 01:00:00
```

Scoped equivalent

To use the `getDisplayValue()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - getDisplayValue()**.

GlideDateTime - getDisplayValueInternal()

Returns the display value in the internal format (yyyy-MM-dd HH:mm:ss). This method is useful for date/time fields, but not for date fields.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### GlideDateTime - getDisplayValueInternal()

The date and time values for the GlideDateTime object in the current user's time zone and the internal date and time format of yyyy-MM-dd HH:mm:ss.

```javascript
// Wednesday
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getDisplayValueInternal());
```

**Output:**

```
2011-08-31 01:00:00
```

### Scoped equivalent

To use the `getDisplayValueInternal()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - getDisplayValueInternal().**

### GlideDateTime - getDSTOffset()

Gets the amount of time that daylight saving time is offset.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Amount of time, in milliseconds, that daylight saving is offset. Returns 0 if there is no offset or if the time is not during daylight saving time.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getDSTOffset());
```

**Output:**

```
3600000
```
Scoped equivalent

To use the `getDSTOffset()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getDSTOffset()`.

GlideDateTime - `getErrorMsg()`

Gets the current error message.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The error message</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-aa-31 aa:00:00"); //bad
gs.print(gdt.isValid()); //false
gs.print(gdt.getErrorMsg());  //reason
```

Output:

false

Could not parse DateTime: 2011-aa-31 aa:00:00

Scoped equivalent

To use the `getErrorMsg()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getErrorMsg()`.

GlideDateTime - `getInternalFormattedLocalTime()`

Returns the object’s time in the local time zone and in the internal format.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The object's time in the local time zone and the internal format.</td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the `getInternalFormattedLocalTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getInternalFormattedLocalTime()`.

**GlideDateTime - getInternalMidnight(Number dayOfTheWeek)**

Returns a date and time object set to midnight of a specified day using UTC.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>dayOfTheWeek</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>GlideDateTime</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getInternalMidnight(2));
```

Output: 2011-08-30 00:00:01

**GlideDateTime - getLocalDate()**

Gets the date stored by the GlideDateTime object, expressed in the standard format, yyyy-MM-dd, and the current user's time zone.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDate</td>
<td>The date in the user's time zone.</td>
</tr>
</tbody>
</table>

```
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getLocalDate());
```

Output: 2011-08-31

**Scoped equivalent**

To use the `getLocalDate()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getLocalDate()`.

**GlideDateTime - getLocalTime()**

Gets the time in the user's time zone.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

```
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getLocalTime());
```

Output: 1970-01-01 01:00:00

**Scoped equivalent**

To use the `getLocalTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getLocalTime()`.
**GlideDateTime - getMonth()**

Retrieves the month stored by the GlideDateTime object, expressed in Java Virtual Machine time zone.

Use `getMonthLocalTime()` and `getMonthUTC()` instead of this method.

---

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The numerical value of the month, Jan=1, Dec=12.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime(); //December
gs.print(gdt.getMonth());

Output: 12
```

---

**GlideDateTime - getMonthLocalTime()**

Gets the month stored by the GlideDateTime object, expressed in the current user's time zone.

---

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The numerical value of the month, Jan=1, Dec=12.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime(); //December
gs.print(gdt.getMonthLocalTime());

Output: 12
```
Scoped equivalent

To use the `getMonthLocalTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getMonthLocalTime()`.

**GlideDateTime - getMonthUTC()**

Gets the month stored by the GlideDateTime object, expressed in the UTC time zone.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Number</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime(); //December
gs.print(gdt.getMonthUTC());
```

Output: 12

Scoped equivalent

To use the `getMonthUTC()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getMonthUTC()`.

**GlideDateTime - getNumericValue()**

 Gets the number of milliseconds since January 1, 1970, 00:00:00 GMT.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of milliseconds since January 1, 1970, 00:00:00 GMT.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getNumericValue());
```

Output: 1314777600000

**GlideDateTime - getSpanTime(Number dayOfWeek)**

Retrieves the amount of time elapsed since the midnight of a specified day to the current time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dayOfWeek</td>
<td>Number</td>
<td>Day of week value from 1 to 7. 1 = Monday, 7 = Sunday.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideTime</td>
<td>The amount of time elapsed since midnight of the specified day. To display the result in user-friendly terms, set the value to GlideDuration.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00"); //Wednesday
var dur = new GlideDuration();
var span = gdt.getSpanTime(1); //how much time since Monday 00:00:00
dur.setValue(span);
gs.print(dur.getDisplayValue());
```

Output: 2 Days 8 Hours

**GlideDateTime - getTime()**

Gets the Unix duration stamp.
### GlideTime

The Unix duration stamp in system format based on GMT time.

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getTime());
```

Output: 1970-01-01 08:00:00

#### Scoped equivalent

To use the `getTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getTime()`.

### GlideDateTime - getTZOffset()

Gets the time zone offset in milliseconds.

```javascript
var gdt = new GlideDateTime();
gdt.getLocalTime(); // PST local time
gs.print(gdt.getTZOffset());
```

Output: -28800000
Scoped equivalent
To use the `getTZOffset()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getTZOffset()`.

GlideDateTime - `getUseUserFormattedLocalTime()`
Returns the object's time in local time zone in the user's format.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

Reached by using the `getUserFormattedLocalTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getUserFormattedLocalTime()`.

GlideDateTime - `getUserTimeZone()`
Retrieves the time zone for the current user session. This method is equivalent to `gs.getSession().getTimeZone()`.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

Scoped equivalent
To use the `getUserFormattedLocalTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getUserFormattedLocalTime()`.

GlideDateTime - `getUserTimeZone()`
Retrieves the time zone for the current user session. This method is equivalent to `gs.getSession().getTimeZone()`.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>TimeZone</td>
</tr>
</tbody>
</table>
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getUserTimeZone());

Output:

sun.util.calendar.ZoneInfo[id=\"America/Los_Angeles\",offset=-28800000,\ndstSavings=3600000,useDaylight=true,transitions=185,
lastRule=java.util.SimpleTimeZone[id=\"America/Los_Angeles\",offset=-28800000,\ndstSavings=3600000,\n0,useDaylight=true,startYear=0,startMode=3,
startMonth=2,startDay=8,startDayOfWeek=1,startTime=7200000,startTimeMode=0,endMode=3,endMonth=10,endDay=1,endDayOfWeek=1,
endTime=7200000,endTimeMode=0]]

**GlideDateTime - getUTCMidnight(Number dayOfTheWeek)**

Retrieves a GlideDateTime object with the time set to midnight using the UTC time zone.

This method sets the date of the new GlideDateTime object as the specified day of the week within the week of the original GlideDateTime object.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>dayOfTheWeek</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>GlideDateTime</td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime("2011-08-31 08:00:00"); // Wednesday, 3rd day of the week. gs.print(gdt.getUTCMidnight(5)); //Friday, 5th day of the week.

Output: 2011-09-02 00:00:00

**GlideDateTime - getValue()**

Gets the date and time value stored by the GlideDateTime object in the internal format, yyyy-MM-dd HH:mm:ss, and the system time zone, UTC by default.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The date and time in the internal format and system time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.getValue());
```

Output:

2011-08-31 08:00:00

Scoped equivalent

To use the `getValue()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - getValue()`.

GlideDateTime - `getWeekOfYearLocalTime()`

Gets the number of the week stored by the GlideDateTime object, expressed in the current user's time zone.

All weeks begin on Sunday. The first week of the year is the week that contains at least one day of the new year. The week beginning Sunday 2015-12-27 is considered the first week of 2016 as that week contains January 1 and 2.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of the current week. The highest week number in a year is either 52 or 53.</td>
</tr>
</tbody>
</table>
var gdt = new GlideDateTime("2011-12-01 12:00:00");
gs.print(gdt.getWeekOfYearUTC());

Output: 49

Scoped equivalent
To use the getWeekOfYearLocalTime() method in a scoped application, use the corresponding scoped method: Scoped GlideDateTime - getWeekOfYearLocalTime().

GlideDateTime - getWeekOfYearUTC()

Gets the number of the week stored by the GlideDateTime object, expressed in the UTC time zone.

All weeks begin on Sunday. The first week of the year is the week that contains at least one day of the new year. The week beginning Sunday 2015-12-27 is considered the first week of 2016 as that week contains January 1 and 2.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of the current week in UTC time. The highest week number in a year is either 52 or 53.</td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime("2011-12-01 12:00:00");
gs.print(gdt.getWeekOfYearUTC());

Output: 49

Scoped equivalent
To use the getWeekOfYearUTC() method in a scoped application, use the corresponding scoped method: Scoped GlideDateTime - getWeekOfYearUTC().
GlideDateTime - `getYear()`

Retrieves the year stored by the GlideDateTime object, expressed in the Java Virtual Machine time zone.

Use `getYearLocalTime()` and `getYearUTC()` instead of this method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The 4-digit year value in the Java Virtual Machine time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime(); //2011
gs.print(gdt.getYear());
```

Output: 2011

GlideDateTime - `getYearLocalTime()`

Gets the year stored by the GlideDateTime object, expressed in the current user's time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The 4-digit year value in the user's time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime(); //2011
gs.print(gdt.getYearLocalTime());
```

Output: 2011
Scoped equivalent

To use the `getYearLocalTime()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - getYearLocalTime()**.

**GlideDateTime - getYearUTC()**

Gets the year stored by the GlideDateTime object, expressed in the UTC time zone.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>number</td>
</tr>
</tbody>
</table>

```
var gdt = new GlideDateTime(); //2011
gs.print(gdt.getYearUTC());
```

Output: 2011

Scoped equivalent

To use the `getYearUTC()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - getYearUTC()**.

**GlideDateTime - GlideDateTime()**

Instantiates a new GlideDateTime object with the current date and time in GMT format.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

```
var gdt = new GlideDateTime();
```
**GlideDateTime - GlideDateTime(String dateTime)**

Instantiates a new GlideDateTime object from a date and time value in the UTC time zone specified with the format yyyy-MM-dd HH:mm:ss.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>String</td>
<td>A UTC date and time using the format yyyy-MM-dd HH:mm:ss.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-01-01 12:00:00");
```

**GlideDateTime - GlideDateTime(GlideDateTime gdt)**

Instantiates a new GlideDateTime object set to the time of a specified GlideDateTime object in GMT format.

The system attempts to match the argument passed to the gdt parameter with the specified internal system format. If the argument does not match the system format, the system attempts to match it to one of the following formats in this order:

- yyyy-MM-dd'T'HH:mm:ss.Z
- MM/dd/yyyy HH:mm:ss
- MM-dd-yyyy HH:mm:ss
- MM-dd-yyyy HH:mm
- MM-dd-yyyy
- MM/dd/yyyy
- dd-MM-yyyy HH:mm:ss
- dd-MM-yyyy HH.mm:ss
- dd-MM-yyyy HH:mm
- dd-MM-yyyy
- yyyy-MM-dd HH:mm
• yyyy-MM-dd
• dd.MM.yyyy HH:mm:ss
• dd.MM.yyyy HH.mm.ss
• dd.MM.yyyy hh:mm:ss a
• dd.MM.yyyy hh.mm.ss a
• dd.MM.yyyy

If one of these formats results in a valid date/time, GlideDateTime.isValid() returns true.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gdt</td>
<td>GlideDateTime</td>
<td>Object used to set the time of the new object.</td>
</tr>
</tbody>
</table>

This example instantiates a GlideDateTime object using the internal system format.

```javascript
var start = new GlideDateTime("2011-01-01 12:00:00");
var end = new GlideDateTime(start);
gs.print(end);
```

Output:

```
2011-01-01 12:00:00
```

This example instantiates a GlideDateTime object using the `yyyy-MM-dd'T'HH:mm:ss.SSSZ` format.

```javascript
var start = new GlideDateTime("2014-07-04T12:08:56.235-0700");
var end = new GlideDateTime(start);
gs.print(end);
```

Output:

```
2014-07-04 19:08:56
```

**GlideDateTime - hasDate()**

Determines if an object's date is set.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the object's date is set, false otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.print(gdt.hasDate());
```

**Output:**

```
true
```

### Scoped equivalent

To use the `hasDate()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - hasDate()**.

### GlideDateTime - isDST()

Determines if the object's time uses a daylight saving offset

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the time is daylight saving time, false otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 00:00:00");
gs.print(gdt.isDST()); //true
```

**Output:**
Scoped equivalent
To use the `isDST()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - isDST()`.

**GlideDateTime - isValid()**
Determines if a value is a valid date and time.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if value is valid, false otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-aa-31 aa:00:00"); //bad
gs.print(gdt.isValid()); //false
gs.print(gdt.getErrorMsg()); //reason
```

Output: false

Scoped equivalent
To use the `isValid()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - isValid()`.

**GlideDateTime - setDayOfMonth(Number day)**
Sets the day of the month to a specified value.

Use `setDayOfMonthLocalTime(day)` and `setDayOfMonthUTC(day)` instead of this method.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>day</td>
<td>Number</td>
<td>Day of the month, from 1 to 31.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime();
gdt.setDayOfMonth(9);
gs.print(gdt.getDayOfMonth());
```

Output: 9

**GlideDateTime - setDayOfMonthLocalTime(Number day)**

Sets the day of the month to a specified value in the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>day</td>
<td>Number</td>
<td>The day of month to change to, from 1 to 31. If this value is greater than the maximum number of days in the month, the value is set to the last day of the month.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime();
gdt.setDayOfMonthLocalTime(9);
gs.print(gdt.getDayOfMonthLocalTime());
```

Output: 9
Scoped equivalent

To use the `setDayOfMonthLocalTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - setDayOfMonthLocalTime(Number day)`.

**GlideDateTime - setDayOfMonthUTC(Number day)**

Sets the day of the month to a specified value in the UTC time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>day</td>
<td>Number</td>
<td>The day of month to change to, from 1 to 31. If this value is greater than</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the maximum number of days in the month, the value is set to the last day</td>
</tr>
<tr>
<td></td>
<td></td>
<td>of the month.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime();
gdt.setDayOfMonthUTC(9);
gs.print(gdt.getDayOfMonthUTC());
```

Output: 9

Scoped equivalent

To use the `setDayOfMonthUTC()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - setDayOfMonthUTC(Number day)`.

**GlideDateTime - setDisplayValue(String asDisplayed)**

Sets a date and time value using the current user's display format and time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asDisplayed</td>
<td>String</td>
<td>The date and time in the current user's display format and time zone. The</td>
</tr>
<tr>
<td></td>
<td></td>
<td>parameter must be formatted</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>using the current user’s preferred display format, such as MM-dd-yyyy HH:mm:ss. To assign the current date and time to a variable in a workflow script, use <code>&lt;variable&gt;.setDisplayValue(gs.nowDateTime);</code>.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-02-02 12:00:00");
gdt.setDisplayValue("2011-01-01 12:00:00");
gs.print(gdt.getValue());
```

Output:

```
2011-01-01 20:00:00
```

Scoped equivalent

To use the `setDisplayValue()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - setDisplayValue(String asDisplayed)**.

**GlideDateTime - setDisplayValue(String dateTime, String format)**

Sets a date and time value using the current user's time zone and the specified date and time format.

This method throws a runtime exception if the date and time format used in the `dateTime` parameter does not match the `format` parameter. You can retrieve the error message by calling `getErrorMsg()` on the GlideDateTime object after the exception is caught.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>String</td>
<td>The date and time in the current user’s time zone.</td>
</tr>
<tr>
<td>format</td>
<td>String</td>
<td>The format to use to parse the dateTime parameter.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-02-02 12:00:00");
gdt.setDisplayValue("20-5-2011 12:00:00", "dd-MM-yyyy HH:mm:ss");
gs.print(gdt.getValue());
```

Output:

```
2011-05-20 19:00:00
```

Scoped equivalent

To use the `setDisplayValue()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - setDisplayValue(String value, String format)`.

**GlideDateTime - setDisplayValueInternal(String dateTime)**

Sets a date and time value using the internal format (yyyy-MM-dd HH:mm:ss) and the current user's time zone.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>String</td>
<td>The date and time in internal format</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-02-02 12:00:00");
gdt.setDisplayValueInternal("2011-01-01 12:00:00");
gs.print(gdt.getValue());
```

Output:

```
2011-01-01 20:00:00
```
Scoped equivalent

To use the `setDisplayValueInternal()` method in a scoped application, use the corresponding scoped method: 

```
Scoped GlideDateTime - setDisplayValueInternal(String value).
```

**GlideDateTime - setDisplayValueInternalWithAlternates(String dateTime)**

Sets a date and time value using the internal format (yyyy-MM-dd HH:mm:ss) and the current user's time zone.

This method attempts to parse incomplete date and time values.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>String</td>
<td>The date and time in internal format.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideDateTime - setGlideDateTime(GlideDateTime gDT)**

Sets the date and time of the current object using an existing GlideDateTime object.

This method is equivalent to instantiating a new object with a GlideDateTime parameter.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gDT</td>
<td>GlideDateTime</td>
<td>A GlideDateTime object</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var dt1 = new GlideDateTime("2011-01-01 12:00:00");
var dt2 = new GlideDateTime("2011-02-02 08:00:00");
dt1.setGlideDateTime(dt2);
gs.print(dt1.getValue());

Output:
2011-02-02 08:00:00

Scoped equivalent
To use the setGlideDateTime() method in a scoped application, use the corresponding scoped method: Scoped GlideDateTime - setGlideDateTime(GlideDateTime g).

GlideDateTime - setInitialValue(String dateTime)
Sets the date and time.
This method is equivalent to setValue(Object).

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>String</td>
<td>The date and time to use. Accepts either a string in the GMT time zone in the internal format, or a GlideDateTime object.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime();
gdt.setInitialValue("2011-01-01 12:00:00");
gs.print(gdt.getValue());

Output: 2011-01-01 12:00:00

GlideDateTime - setMonth(Number month)
Sets the month stored by the GlideDateTime object to a specified value using the Java Virtual Machine time zone.

Use setMonthLocalTime() or setMonthUTC() instead of this method.
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>month</td>
<td>Number</td>
<td>The month to change to.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime();
gdt.setMonth(1);
gs.print(gdt.getMonth());
```

Output: 1

**GlideDateTime - setMonthLocalTime(Number month)**

Sets the month stored by the GlideDateTime object to a specified value using the current user's time zone.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>month</td>
<td>Number</td>
<td>The month to change to.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime();
gdt.setMonthLocalTime(1);
gs.print(gdt.getMonthLocalTime());
```

Output: 1
Scoped equivalent
To use the `setMonthLocalTime()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - setMonthLocalTime(Number month)`. 

GlideDateTime - `setMonthUTC(Number month)`
Sets the month stored by the GlideDateTime object to a specified value using the UTC time zone.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>month</td>
<td>Number</td>
<td>The month to change to.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime();
gdt.setMonthUTC(1);
gs.print(gdt.getMonthUTC());
```

Output: 1

Scoped equivalent
To use the `setMonthUTC()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - setMonthUTC(Number month)`. 

GlideDateTime - `setNumericValue(Number milliseconds)`
Sets the date and time to the number of milliseconds since January 1, 1970 00:00:00 GMT.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>Number of milliseconds</td>
</tr>
</tbody>
</table>

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime();
gdt.setNumericValue(1314777600000);
gs.print(gdt.getValue());
```

Output: 2011-08-31 08:00:00

**GlideDateTime - setTZ(TimeZone timeZone)**

Sets the time zone of the GlideDateTime object to be the specified time zone.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeZone</td>
<td>TimeZone</td>
<td>A time zone object</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var tz = gs.getSession().getTimeZone();
var gdt = new GlideDateTime();
gdt.setTZ(tz);
```

**GlideDateTime - setValue(Object dateTime)**

Sets the date and time of the GlideDateTime object.

This method is equivalent to `setInitialValue()`.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>Object</td>
<td>The date and time to use. This parameter may be one of several types.</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>- A string in the UTC time zone and the internal format of yyyy-MM-dd HH:mm:ss: Sets the value of the object to the specified date and time. Using the method this way is equivalent to instantiating a new GlideDateTime object using the GlideDateTime(value) constructor. If the date and time format used does not match the internal format, the method attempts to set the date and time using other available formats. Resolving the date and time this way can lead to inaccurate data due to ambiguity in the day and month values. When using a non-standard date and time format, use setValueUTC(dateTime, format) instead.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- A GlideDateTime object: Sets the value of the object to the date and time stored by the GlideDateTime passed in the parameter. Using the method this way is equivalent to instantiating a new GlideDateTime object using the GlideDateTime(g) Constructor.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- A Java Date object: Sets the value of the object using the value stored by the Java Date object. Using the method this way is equivalent to passing the value returned by the Java Date object getTime() to the GlideDateTime setNumericValue() method. This method does not accept JavaScript Date objects.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- A JavaScript Number: Sets the value of the object using the Number value as milliseconds past January 1, 1970 00:00:00 GMT. Using the method this way is equivalent to the setNumericValue(milliseconds) method.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- A Java Integer or Long: Sets the value of the object using the Integer or Long value as milliseconds past January 1, 1970 00:00:00 GMT. Using the method this way is equivalent to the setNumericValue(milliseconds) method.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
Set the date and time using a string in yyyy-MM-dd HH:mm:ss format.

```javascript
var gdt = new GlideDateTime("2011-01-01 12:00:00");
gdt.setValue("2011-02-02 08:00:00");
gs.print(gdt.getValue());
```

Output:

```
2011-02-02 08:00:00
```

Set the date and time using an existing GlideDateTime object.

```javascript
var gdtSource = new GlideDateTime("2017-05-23 11:37:41");
var gdtDest = new GlideDateTime();
gdtDest.setValue(gdtSource);
gs.print(gdtDest.getValue());
```

Output:

```
2017-05-23 11:37:41
```

Set the date and time using a number indicating milliseconds past January 1, 1970 00:00:00 GMT.

```javascript
var gdt = new GlideDateTime("2011-01-01 12:00:00");
gdt.setValue(1617634522375);
gs.print(gdt.getValue());
```

Output:

```
2021-04-05 14:55:22
```

**Scoped equivalent**

To use the `setValue()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - setValue(String o).**

**GlideDateTime - setValueUTC(String dateTime, String format)**

Sets a date and time value using the UTC time zone and the specified date and time format.

This method throws a runtime exception if the date and time format used in the `dateTime` parameter does not match the format parameter. You can retrieve the error message by calling `getErrorMsg()` on the GlideDateTime object after the exception is caught.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>String</td>
<td>The date and time to use.</td>
</tr>
<tr>
<td>format</td>
<td>String</td>
<td>The format to use.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-01-01 12:00:00");
gdt.setValueUTC("15-02-2011 08:00:00", "dd-MM-yyyy HH:mm:ss");
gs.print(gdt.getValue());
```

Output:

2011-02-15 08:00:00

Scoped equivalent

To use the `setValueUTC()` method in a scoped application, use the corresponding scoped method: **Scoped GlideDateTime - setValueUTC(String dt, String format)**.

GlideDateTime - setYear(Number year)

Sets the year stored by the GlideDateTime object to a specified value using the Java Virtual Machine time zone.

Use `setYearLocalTime()` or `setYearUTC()` instead of this method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>Number</td>
<td>The year to change to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var gdt = new GlideDateTime();
gdt.setYear(2013);
gs.print(gdt.getYear());

Output: 2013

GlideDateTime - setYearLocalTime(Number year)
Sets the year stored by the GlideDateTime object to a specified value using the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>Number</td>
<td>The year to change to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime();
gdt.setYearLocalTime(2013);
gs.print(gdt.getYearLocalTime());

Output: 2013

Scoped equivalent
To use the setYearLocalTime() method in a scoped application, use the corresponding scoped method: Scoped GlideDateTime - setYearLocalTime(Number year).

GlideDateTime - setYearUTC(Number year)
Sets the year stored by the GlideDateTime object to a specified value using the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>Number</td>
<td>The year to change to.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime();
gdt.setYearUTC(2013);
gs.print(gdt.getYearUTC());
```

Output: 2013

**Scoped equivalent**

To use the `setYearUTC()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - setYearUTC(Number year)`.

**GlideDateTime - subtract(GlideTime time)**

Subtracts a specified amount of time.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>GlideTime</td>
<td>The time to subtract</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
var gtime1 = new GlideTime();
gtime1.setValue("00:00:20");
gdt.subtract(gtime1);
gs.print(gdt.getTime());
```

Output: 1970-01-01 07:59:40

**Scoped equivalent**

To use the `subtract()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - subtract(GlideTime time)`. 
**GlideDateTime - subtract(Number milliseconds)**

Subtracts a specified number of milliseconds from the GlideDateTime object.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>The number of milliseconds to subtract</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-07 08:00:00");
gdt.subtract(1000);
gs.print(gdt.getValue());
```

Output: 2011-12-07 07:59:59

**Scoped equivalent**

To use the `subtract()` method in a scoped application, use the corresponding scoped method: `Scoped GlideDateTime - subtract(Number milliseconds)`.

**GlideDateTime - subtract(GlideDateTime start, GlideDateTime end)**

Gets the duration difference between two GlideDateTime values.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>start</td>
<td>GlideDateTime</td>
<td>The start value</td>
</tr>
<tr>
<td>end</td>
<td>GlideDateTime</td>
<td>The end value</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDuration</td>
<td>The time between the two values</td>
</tr>
</tbody>
</table>

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Output: 2 Days 23 Hours

Scoped equivalent
To use the `subtract()` method in a scoped application, use the corresponding scoped method: Scoped GlideDateTime - `subtract(GlideDateTime start, GlideDateTime end)`.

GlideDateTime - toString()
Returns the date and time value stored by the GlideDateTime object in the internal format, `yyyy-MM-dd HH:mm:ss`, and the system time zone, UTC by default.

This method is equivalent to `getValue()`.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The date and time stored by the GlideDateTime object in the system time zone and format.</td>
</tr>
</tbody>
</table>

Output: 2011-08-31 08:00:00

Scoped equivalent
To use the `toString()` method in a scoped application, use the corresponding scoped method: Scoped GlideDateTime - `toString()`.
GlideDateTime - Scoped

The scoped GlideDateTime class provides methods for performing operations on GlideDateTime objects, such as instantiating GlideDateTime objects or working with glide_date_time fields.

Use the GlideDateTime methods to perform date-time operations, such as instantiating a GlideDateTime object, performing date-time calculations, formatting a date-time, or converting between date-time formats.

Scoped GlideDateTime - add(GlideTime gd)

Adds a GlideTime object to the current GlideDateTime object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gd</td>
<td>GlideTime</td>
<td>GlideTime object whose time value to add to the specified GlideDateTime object.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
var gtime1 = new GlideTime();
gtime1.setValue("00:00:20");
gdt.add(gtime1);
var gtime2 = gdt.getTime();
gs.info(gtime2.getByFormat('hh:mm:ss'));
```

**Output:**

08:00:20

Scoped GlideDateTime - add(Number milliseconds)

Adds the specified number of milliseconds to the current GlideDateTime object.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>The number of milliseconds to add.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.info(gdt.getNumericValue());
gdt.add(10);
gs.info(gdt.getNumericValue());
```

Output:

1314777600000 1314777600010

**Scoped GlideDateTime - addDaysLocalTime(Number days)**

Adds a specified number of days to the current GlideDateTime object. A negative parameter subtracts days. The method determines the local date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts days using the local date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>Number</td>
<td>The number of days to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addDaysLocalTime(-1);
gs.info(gdt.getLocalDate());
gs.info(gdt.getNumericValue());
```

Output:

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Scoped GlideDateTime - addDaysUTC(Number days)

Adds a specified number of days to the current GlideDateTime object. A negative parameter subtracts days. The method determines the UTC date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts days using the UTC date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>Number</td>
<td>The number of days to add. Use a negative number to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addDaysUTC(-1);
gs.info(gdt.getDate());
```

Output:

2011-08-30

Scoped GlideDateTime - addMonthsLocalTime(Number months)

Adds a specified number of months to the current GlideDateTime object. A negative parameter subtracts months. The method determines the local date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts months using the local date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>The number of months to add. use a negative value to subtract.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addMonthsLocalTime(2);
gs.info(gdt.getDate());
```

Output: 2011-10-31

**Scoped GlideDateTime - addMonthsUTC(Number months)**

Adds a specified number of months to the current GlideDateTime object. A negative parameter subtracts months. The method determines the UTC date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts months using the UTC date and time values.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>The number of months to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addMonthsUTC(2);
gs.info(gdt.getDate());
```

**Scoped GlideDateTime - addSeconds(Number seconds)**

Adds the specified number of seconds to the current GlideDateTime object.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seconds</td>
<td>Number</td>
<td>The number of seconds to add.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-07 08:00:00");
gdt.addSeconds(1000);
gs.info(gdt.getValue());
```

Output: 2011-12-07 08:16:40

**Scoped GlideDateTime - addWeeksLocalTime(Number weeks)**

Adds a specified number of weeks to the current GlideDateTime object. A negative parameter subtracts weeks. The method determines the local date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts weeks using the local date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>weeks</td>
<td>Number</td>
<td>The number of weeks to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addWeeksLocalTime(-1);
gs.info(gdt.getDate());
```

Output: 2011-08-24
Scoped GlideDateTime - addWeeksUTC(Number weeks)

Adds a specified number of weeks to the current GlideDateTime object. A negative parameter subtracts weeks. The method determines the UTC date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts weeks using the UTC date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>weeks</td>
<td>Number</td>
<td>The number of weeks to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime("2011-08-31 08:00:00");
gdt.addWeeksUTC(-1);
gdt.addWeeksUTC(-1);
gs.info(gdt.getDate());

Output: 2011-08-24

Scoped GlideDateTime - addYearsLocalTime(Number years)

Adds a specified number of years to the current GlideDateTime object. A negative parameter subtracts years. The method determines the local date and time equivalent to the value stored by the GlideDateTime object, then adds or subtracts years using the local date and time values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>years</td>
<td>Number</td>
<td>The number of years to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
```javascript
var gdt = new GlideDateTime("2010-08-31 08:00:00");
gdt.addYearsLocalTime(1);
gs.info(gdt.getDate());
```

Output: 2011-08-31

**Scoped GlideDateTime - addYearsUTC(Number years)**

Adds a specified number of years to the current GlideDateTime object. A negative parameter subtracts years. The date and time value stored by GlideDateTime object is interpreted as being in the UTC time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>years</td>
<td>Number</td>
<td>The number of years to add. Use a negative value to subtract.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2010-08-31 08:00:00");
gdt.addYearsUTC(1);
gs.info(gdt.getDate());
```

Output: 2011-08-31

**Scoped GlideDateTime - after(GlideDateTime gdt)**

Determines if the GlideDateTime object's date and time occurs after the specified object's date and time.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gdt</td>
<td>GlideDateTime</td>
<td>Date and time to check against.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean| Flag that indicates whether the GlideDateTime object's date and time is after the date and time specified by the parameter. Possible values:  
  • true: GlideDateTime object date and time is after the specified object's date and time.  
  • false: GlideDateTime object date and time is before or equal to the specified object's date and time. |

var gdt1 = new GlideDateTime("2016-05-09 10:11:12");
var gdt2 = new GlideDateTime("2017-06-12 15:11:12");
gs.info(gdt1.after(gdt2));

Output: False

Scoped GlideDateTime - before(GlideDateTime gdt)

Determines if the GlideDateTime object's date and time occurs before the specified GlideDateTime object's date and time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gdt</td>
<td>GlideDateTime</td>
<td>Date and time to check against.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean| Flag that indicates whether the GlideDateTime object's date and time is before the date and time specified by the parameter. Possible values:  
  • true: GlideDateTime object date and time is before the specified date and time.  
  • false: GlideDateTime object date and time is after or equal to the specified date and time. |
var gdt1 = new GlideDateTime("2016-05-09 10:11:12");
var gdt2 = new GlideDateTime("2017-06-12 15:11:12");
gs.info(gdt1.before(gdt2));

Output
true

Scoped GlideDateTime - compareTo(Object o)

Compares two date and time objects to determine whether they are equivalent or one occurs before or after the other.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>o</td>
<td>Object</td>
<td>Date and time object in GlideDateTime format</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Number | 0 = Dates are equal  
|      | 1 = The object's date is after the date specified in the parameter  
|      | -1 = The object's date is before the date specified in the parameter  |

var initDate = new GlideDateTime("2011-08-01 12:00:00");
var compDate1 = new GlideDateTime("2011-08-01 12:00:00");
var compDate2 = new GlideDateTime("2011-07-31 12:00:00");
var compDate3 = new GlideDateTime("2011-08-04 16:00:00");
gs.info(initDate.compareTo(compDate1)); // Equals (0)
gs.info(initDate.compareTo(compDate2)); // initDate is after compDate2 (1)
gs.info(initDate.compareTo(compDate3)); // initDate is before compDate3 (-1)

Scoped GlideDateTime - equals(Object dateTime)

Compares a datetime with an existing value for equality.
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTime</td>
<td>GlideDateTime object or String</td>
<td>The datetime to compare.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if they are equal; otherwise, false.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 00:00:00");
gs.info(gdt.equals("2011-09-30 00:12:01"));
```

Output: false

**Scoped GlideDateTime - getDate()**

Gets the date stored by the GlideDateTime object, expressed in the standard format, yyyy-MM-dd, and the system time zone, UTC by default.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDate</td>
<td>The date in the system time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.info(gdt.getDate());
```

**Scoped GlideDateTime - getDayOfMonthLocalTime()**

Gets the day of the month stored by the GlideDateTime object, expressed in the current user's time zone.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The day of the month in the user's time zone, from 1 to 31.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-02 12:00:00");
gs.info(gdt.getDayOfMonthLocalTime());
```

### Scoped GlideDateTime - getDayOfMonthUTC()

Gets the day of the month stored by the GlideDateTime object, expressed in the UTC time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The day of the month in the UTC time zone, from 1 to 31.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-02 12:00:00");
gs.info(gdt.getDayOfMonthUTC());
```

Output: 02

### Scoped GlideDateTime - getDayOfWeekLocalTime()

Gets the day of the week stored by the GlideDateTime object, expressed in the user's time zone.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The day of week value, in the user's time zone, from 1 to 7. Monday equals 1, Sunday equals 7.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-01 12:00:00"); //Thursday
gs.info(gdt.getDayOfWeekLocalTime());
```

### Scoped GlideDateTime - getDayOfWeekUTC()

Gets the day of the week stored by the GlideDateTime object, expressed in the UTC time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The day of week value from 1 to 7. Monday equals 1, Sunday equals 7.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-01 12:00:00"); //Thursday
gs.info(gdt.getDayOfWeekLocalTime());
```

### Scoped GlideDateTime - getDaysInMonthLocalTime()

Gets the number of days in the month stored by the GlideDateTime object, expressed in the current user's time zone.

```javascript
var gdt = new GlideDateTime("2011-12-01 12:00:00"); //Thursday
gs.info(gdt.getDayOfWeekLocalTime());
```
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of days in the current month in the user's time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-02 12:00:00"); //December
gs.info(gdt.getDaysInMonthLocalTime());
```

**Scoped GlideDateTime - getDaysInMonthUTC()**

Gets the number of days in the month stored by the GlideDateTime object, expressed in the UTC time zone.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of days in the month stored by the GlideDateTime object, expressed in the UTC time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-11-02 12:00:00"); //November
gs.info(gdt.getDaysInMonthUTC());
```

**Scoped GlideDateTime - getDisplayValue()**

Gets the date and time value in the current user's display format and time zone.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The date and time in the user's format and time zone. Keep in mind when designing business rules or script includes that this method may return values in different formats for different users.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.info(gdt.getDisplayValue()); //uses current user session time zone (US/Pacific)
```

**Scoped GlideDateTime - getDisplayValueInternal()**

Gets the display value in the internal format (yyyy-MM-dd HH:mm:ss).

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The date and time values for the GlideDateTime object in the current user's time zone and the internal date and time format of yyyy-MM-dd HH:mm:ss.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.info(gdt.getDisplayValueInternal()); //uses current user session time zone (US/Pacific)
```

**Scoped GlideDateTime - getDSTOffset()**

Gets the amount of time that daylight saving time is offset.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Amount of time, in milliseconds, that daylight saving is offset. Returns 0 if there is no offset or if the time is not during daylight saving time.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2014-08-31 08:00:00");
gs.info(gdt.getDSTOffset()); //uses current user session time zone (US/Pacific)
```

Scoped GlideDateTime - getErrorMsg()

Gets the current error message.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The error message.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime();
gdt.setDisplayValue("2011-aa-01 00:00:00");
gs.info(gdt.getErrorMsg());
```

Output: Could not parse DateTime: 2011-aa-01 00:00:00

Scoped GlideDateTime - getInternalFormattedLocalTime()

Returns the object's time in the local time zone and in the internal format.

© 2021 ServiceNow, Inc. All rights reserved.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The object's time in the local time zone and the internal format.</td>
</tr>
</tbody>
</table>

Scoped GlideDateTime - getLocalDate()

Gets the date stored by the GlideDateTime object, expressed in the standard format, yyyy-MM-dd, and the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDate</td>
<td>The date in the user's time zone.</td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.info(gdt.getLocalDate());

Scoped GlideDateTime - getLocalTime()

Returns a GlideTime object that represents the time portion of the GlideDateTime object in the user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideTime</td>
<td>The time in the user's time zone.</td>
</tr>
</tbody>
</table>

```
var gdt = new GlideDateTime("2014-08-31 08:00:00");
gt = gdt.getLocalTime();
gs.info("local time is " + gt.getByFormat('hh:mm:ss'));
```

Scoped GlideDateTime - getMonthLocalTime()

Gets the month stored by the GlideDateTime object, expressed in the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The numerical value of the month.</td>
</tr>
</tbody>
</table>

```
var gdt = new GlideDateTime("2011-11-02 12:00:00"); //November
gs.info(gdt.getMonthLocalTime());
```

Scoped GlideDateTime - getMonthUTC()

Gets the month stored by the GlideDateTime object, expressed in the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The numerical value of the month.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-11-02 12:00:00"); //November
gs.info(gdt.getMonthUTC());
```

**Scoped GlideDateTime - getNumericValue()**

Gets the number of milliseconds since January 1, 1970, 00:00:00 GMT.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of milliseconds since January 1, 1970, 00:00:00 GMT.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.info(gdt.getNumericValue());
```

**Scoped GlideDateTime - getTime()**

Returns a GlideTime object that represents the time portion of the GlideDateTime object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideTime</td>
<td>The Unix duration stamp in system format based on GMT time.</td>
</tr>
</tbody>
</table>
var gdt = new GlideDateTime("2014-08-31 08:00:00");
gt = gdt.getTime();
gs.info(gt.getByFormat('hh:mm:ss'));

Scoped GlideDateTime - getTZOffset()
Gets the time zone offset in milliseconds.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of milliseconds of time zone offset.</td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime();
gdt.getLocalTime(); // PST local time
gs.info(gdt.getTZOffset());

Output: -25200000

Scoped GlideDateTime - getUserFormattedLocalTime()
Returns the object's time in the local time zone and in the user's format.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The object's time in the local time zone and in the user's format.</td>
</tr>
</tbody>
</table>
Scoped GlideDateTime - getValue()

Gets the date and time value stored by the GlideDateTime object in the internal format, yyyy-MM-dd HH:mm:ss, and the system time zone, UTC by default.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String - The date and time value in the internal format and system time zone.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2014-08-31 08:00:00");
gs.info(gdt.getValue());
```

Scoped GlideDateTime - getWeekOfYearLocalTime()

Gets the number of the week stored by the GlideDateTime object, expressed in the current user's time zone. All weeks begin on Sunday. The first week of the year is the week that contains at least one day of the new year. The week beginning Sunday 2015-12-27 is considered the first week of 2016 as that week contains January 1 and 2.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number - The number of the current week in local time. The highest week number in a year is either 52 or 53.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-01 12:00:00"); // 49th week, 1st week in december
gs.info(gdt.getWeekOfYearLocalTime());
```
Scoped GlideDateTime - getWeekOfYearUTC()

Gets the number of the week stored by the GlideDateTime object, expressed in the UTC time zone. All weeks begin on Sunday. The first week of the year is the week that contains at least one day of the new year. The week beginning Sunday 2015-12-27 is considered the first week of 2016 as that week contains January 1 and 2.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td></td>
<td></td>
</tr>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Number - The number of the current week in UTC time. The highest week number in a year is either 52 or 53.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-12-01 12:00:00"); // 49th week, 1st week in december
gs.info(gdt.getWeekOfYearUTC());
```

Scoped GlideDateTime - getYearLocalTime()

Gets the year stored by the GlideDateTime object, expressed in the current user's time zone.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td></td>
<td></td>
</tr>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Number - Four-digit year value in the user's time zone.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-11-02 12:00:00");
gs.info(gdt.getYearLocalTime());
```
Scoped GlideDateTime - getYearUTC()

Gets the year stored by the GlideDateTime object, expressed in the UTC time zone.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Number</td>
<td>4-digit year value in the UTC time zone.</td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime("2011-11-02 12:00:00");
gs.info(gdt.getYearUTC());

Scoped GlideDateTime - GlideDateTime()

Instantiates a new GlideDateTime object with the current date and time in Greenwich Mean Time (GMT).

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime();

Scoped GlideDateTime - GlideDateTime(GlideDateTime g)

Instantiates a new GlideDateTime object set to the time of the GlideDateTime object passed in the parameter.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>g</td>
<td>GlideDateTime</td>
<td>The GlideDateTime object to use for setting the time of the new object.</td>
</tr>
</tbody>
</table>
var start = new GlideDateTime("2011-01-01 12:00:00");
var end = new GlideDateTime(start);
gs.info(end);

Scoped GlideDateTime - GlideDateTime(String value)

Instantiates a new GlideDateTime object from a date and time value in the UTC time zone specified with the format yyyy-MM-dd HH:mm:ss.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>A UTC date and time using the internal format yyyy-MM-dd HH:mm:ss.</td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime("2011-01-01 12:00:00");

Scoped GlideDateTime - hasDate()

Determines if an object's date is set.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the object date is set; otherwise, returns false.</td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.info(gdt.hasDate());

Scoped GlideDateTime - isDST()

Determines if an object's time uses a daylight saving offset.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the time is daylight saving; otherwise, returns false.</td>
</tr>
</tbody>
</table>

```java
var gdt = new GlideDateTime("2014-08-31 00:00:00");
gs.info(gdt.isDST()); //true
```

Output:

**Scoped GlideDateTime - isValid()**

Determines if a value is a valid date and time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if value is valid; otherwise, returns false.</td>
</tr>
</tbody>
</table>

```java
var gdt = new GlideDateTime();
gdt.setDisplayValue("2011-aa-01 00:00:00");
gs.info(gdt.isValid());
```

Output: false

**Scoped GlideDateTime - onOrAfter(GlideDateTime gdt)**

Determines if the GlideDateTime object's data and time occurs on or after the specified GlideDateTime object's date and time.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gdt</td>
<td>GlideDateTime</td>
<td>Date and time to check against.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the GlideDateTime object's date and time is on or after the date and time specified by the parameter. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: GlideDateTime object date and time is on or after the specified object's date and time.</td>
</tr>
<tr>
<td></td>
<td>• false: GlideDateTime object date and time is before the specified object's date and time.</td>
</tr>
</tbody>
</table>

```
var gdt1 = new GlideDateTime("2016-05-09 10:11:12");
var gdt2 = new GlideDateTime("2017-06-12 15:11:12");
gs.info(gdt1.onOrAfter(gdt2));
```

Output

false

Scoped GlideDateTime - onOrBefore(GlideDateTime gdt)

Determines if the GlideDateTime object's data and time occurs on or before the specified GlideDateTime object's date and time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gdt</td>
<td>GlideDateTime</td>
<td>Date and time to check against.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the GlideDateTime object's date and time is on or before the date and time specified by the parameter. Possible values:</td>
</tr>
</tbody>
</table>

Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• true: GlideDateTime object date and time is on or before the specified object's date and time.</td>
<td></td>
</tr>
<tr>
<td>• false: GlideDateTime object date and time is after the specified object's date and time.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt1 = new GlideDateTime("2016-05-09 10:11:12");
var gdt2 = new GlideDateTime("2017-06-12 15:11:12");
gs.info(gdt1.onOrBefore(gdt2));
```

Output

```
true
```

**Scoped GlideDateTime - setDayOfMonthLocalTime(Number day)**

Sets the day of the month to a specified value in the current user's time zone.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>day</td>
<td>Number</td>
<td>The day of month to change to, from 1 to 31. If this value is greater than the maximum number of days in the month, the value is set to the last day of the month.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime();
gdt.setDayOfMonthLocalTime(9);
gs.info(gdt.getDayOfMonthLocalTime());
```

**Scoped GlideDateTime - setDayOfMonthUTC(Number day)**

Sets the day of the month to a specified value in the UTC time zone.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>day</td>
<td>Number</td>
<td>The day of month to change to, from 1 to 31. If this value is greater than</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the maximum number of days in the month, the value is set to the last day</td>
</tr>
<tr>
<td></td>
<td></td>
<td>of the month.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime();
gdt.setDayOfMonthUTC(9);
gs.info(gdt.getDayOfMonthUTC());
```

### Scoped GlideDateTime - setDisplayValue(String asDisplayed)

Sets a date and time value using the current user's display format and time zone.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asDisplayed</td>
<td>String</td>
<td>The date and time in the current user's display format and time zone. The</td>
</tr>
<tr>
<td></td>
<td></td>
<td>parameter must be formatted using the current user's preferred display</td>
</tr>
<tr>
<td></td>
<td></td>
<td>format, such as MM-dd-yyyy HH:mm:ss. To assign the current date and time to</td>
</tr>
<tr>
<td></td>
<td></td>
<td>a variable in a workflow script, use variable.setDisplayValue(gs.nowDateTime);.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2014-02-02 12:00:00");
gdt.setDisplayValue("2014-01-01 12:00:00"); //uses current user session time zone (US/Pacific)
gs.info(gdt.getValue());
```
Scoped GlideDateTime - setDisplayValue(String value, String format)

Sets a date and time value using the current user’s time zone and the specified
date and time format.

This method throws a runtime exception if the date and time format used in the
value parameter does not match the format parameter. You can retrieve the
error message by calling getErrorMsg() on the GlideDateTime object after the
exception is caught.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>Date and time in the current user’s time zone.</td>
</tr>
</tbody>
</table>
| format| String | Date and time format to use to parse the value parameter. Use the following values to describe the value parameter:  
• dd: Day of the month  
• MM: Month of the year  
• yyyy: Year  
• HH: Hour  
• mm: Minutes  
• ss: Seconds

For example: "dd-MM-yyyy HH:mm:ss" or "MM-dd-yyyy HH:mm".

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-02-02 12:00:00");
gdt.setDisplayValue("20-5-2011 12:00:00", "dd-MM-yyyy HH:mm:ss"); //uses current user session time zone
gs.info(gdt.getValue());
```

**Output**

"20-05-2011 12:00:00"
Scoped GlideDateTime - setDisplayValueInternal(String value)
Sets a date and time value using the internal format (yyyy-MM-dd HH:mm:ss) and the current user's time zone.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>The date and time in internal format.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
var gdt = new GlideDateTime("2014-02-02 12:00:00");
gdt.setDisplayValueInternal("2014-01-01 12:00:00"); //uses current user session time zone (US/Pacific)
gs.info(gdt.getValue());
```

Scoped GlideDateTime - setGlideDateTime(GlideDateTime g)
Sets the date and time of the current object using an existing GlideDateTime object. This method is equivalent to instantiating a new object with a GlideDateTime parameter.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>g</td>
<td>GlideDateTime</td>
<td>The object to use for setting the datetime value.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
var dt1 = new GlideDateTime("2011-01-01 12:00:00");
var dt2 = new GlideDateTime("2011-02-02 08:00:00");
dt1.setGlideDateTime(dt2);
gs.info(dt1.getValue());
```
Scoped GlideDateTime - setMonthLocalTime(Number month)

Sets the month stored by the GlideDateTime object to the specified value using the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>month</td>
<td>Number</td>
<td>The month to change to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime();
gdt.setMonthLocalTime(1);
gs.info(gdt.getMonthLocalTime());

Output: 1

Scoped GlideDateTime - setMonthUTC(Number month)

Sets the month stored by the GlideDateTime object to the specified value using the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>month</td>
<td>Number</td>
<td>The month to change to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime();
gdt.setMonthUTC(1);
gs.info(gdt.getMonthUTC());

Output: 1
Scoped GlideDateTime - setValue(String o)

Sets the date and time of the GlideDateTime object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>o</td>
<td>String</td>
<td>The date and time to use. This parameter may be one of several types:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A string in the UTC time zone and the internal format of yyyy-MM-dd HH:mm:ss. Sets the value of the object to the specified date and time. Using the method this way is equivalent to instantiating a new GlideDateTime object using the GlideDateTime(String value) constructor. If the date and time format used does not match the internal format, the method attempts to set the date and time using other available formats. Resolving the date and time this way can lead to inaccurate data due to ambiguity in the day and month values. When using a non-standard date and time format, use setValueUTC(String dt, String format) instead.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A GlideDateTime object. Sets the value of the object to the date and time stored by the GlideDateTime passed in the parameter. Using the method this way is equivalent to instantiating a new GlideDateTime object using the GlideDateTime(GlideDateTime g) constructor.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• A JavaScript Number. Sets the value of the object using the Number value as milliseconds past January 1, 1970 00:00:00 GMT.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-01-01 12:00:00");
gdt.setValue("2011-02-02 08:00:00"); // value set = 2011-02-02 08:00:00
gs.info(gdt.getValue());
```
Scoped GlideDateTime - setValueUTC(String dt, String format)

Sets a date and time value using the UTC time zone and the specified date and time format. This method throws a runtime exception if the date and time format used in the dt parameter does not match the format parameter. You can retrieve the error message by calling getErrorMsg() on the GlideDateTime object after the exception is caught.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dt</td>
<td>String</td>
<td>The date and time to use.</td>
</tr>
<tr>
<td>format</td>
<td>String</td>
<td>The date and time format to use.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-01-01 12:00:00");
gdt.setValueUTC("15-02-2011 08:00:00", "dd-MM-yyyy HH:mm:ss");
gs.info(gdt.getValue());
```

Scoped GlideDateTime - setYearLocalTime(Number year)

Sets the year stored by the GlideDateTime object to the specified value using the current user's time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>Number</td>
<td>The year to change to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var gdt = new GlideDateTime();
gdt.setYearLocalTime(2013);
gs.info(gdt.getYearLocalTime());

Output: 2013

Scoped GlideDateTime - setYearUTC(Number year)
Sets the year stored by the GlideDateTime object to the specified value using the UTC time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>Number</td>
<td>The year to change to.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime();
gdt.setYearUTC(2013);
gs.info(gdt.getYearUTC());

Output: 2013

Scoped GlideDateTime - subtract(GlideTime time)
Subtracts a specified amount of time from the current GlideDateTime object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>GlideTime</td>
<td>The time value to subtract.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var gdt = new GlideDateTime("2011-08-31 08:00:00");
var gtime1 = new GlideTime();
gtime1.setValue("00:00:20");
gdt.subtract(gtime1);
var gtime2 = gdt.getTime();
gs.info(gtime2.getByFormat('hh:mm:ss'));

Output: 07:59:40

**Scoped GlideDateTime - subtract(Number milliseconds)**
Subtracts the specified number of milliseconds from the GlideDateTime object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>Number of milliseconds to subtract.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var gdt = new GlideDateTime("2011-12-07 08:00:00");
gdt.subtract(1000);
gs.info(gdt.getValue());

Output: 2011-12-07 07:59:59

**Scoped GlideDateTime - subtract(GlideDateTime start, GlideDateTime end)**
Gets the duration difference between two GlideDateTime values.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start</td>
<td>GlideDateTime</td>
<td>The start value.</td>
</tr>
<tr>
<td>End</td>
<td>GlideDateTime</td>
<td>The end value.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDuration</td>
<td>The duration between the two values.</td>
</tr>
</tbody>
</table>

```javascript
var gdt1 = new GlideDateTime("2011-08-28 09:00:00");
var gdt2 = new GlideDateTime("2011-08-31 08:00:00");

var dur = GlideDateTime.subtract(gdt1, gdt2); //the difference between gdt1 and gdt2
gs.info(dur.getDisplayValue());
```

Output: 2 Days 23 Hours

**Scoped GlideDateTime - toString()**

Gets the date and time value stored by the GlideDateTime object in the internal format, yyyy-MM-dd HH:mm:ss, and the system time zone, UTC by default. This method is equivalent to getValue().

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The date and time stored by the GlideDateTime object in the system time zone and format.</td>
</tr>
</tbody>
</table>

```javascript
var gdt = new GlideDateTime("2011-08-31 08:00:00");
gs.info(gdt.toString());
```

**GlideDBFunctionBuilder - Scoped, Global**

Build functions to perform SQL operations in the database.

The GlideDBFunctionBuilder methods provide a way to build Relational Database Management System (RDBMS) functions to perform SQL operations on record data. These methods can be used in both scoped and global server scripts.

To use platform functions:
• Construct a function using the GlideDBFunctionBuilder constructor and associated methods.

• After building a function, you can apply the function to the current record using the addFunction() method of the GlideRecord class.

• Add the function to a query using the addQuery() method of the GlideRecord class.

• Retrieve the results of the function using the existing GlideRecord API methods such as getValue() and getElement().

Scoped GlideDBFunctionBuilder - add()
Adds the values of two or more integer fields.

Use the field(String field) method to define fields on which the operation is performed.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Parameters

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var functionBuilder = new GlideDBFunctionBuilder();
var myAddingFunction = functionBuilder.add();
myAddingFunction = functionBuilder.field('order');
myAddingFunction = functionBuilder.field('priority');
myAddingFunction = functionBuilder.build();

Scoped GlideDBFunctionBuilder - build()
Builds the database function defined by the GlideDBFunctionBuilder object.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var functionBuilder = new GlideDBFunctionBuilder();
var myAddingFunction = functionBuilder.add();
myAddingFunction = functionBuilder.field('order');
myAddingFunction = functionBuilder.field('priority');
myAddingFunction = functionBuilder.build();
gs.info(myAddingFunction);
```

Output:

```plaintext
*** Script: glidefunction:add(order,priority)
```

Scoped GlideDBFunctionBuilder - concat()

Concatenates the values of two or more fields.

Use the `field(String field)` method to define fields on which the operation is performed.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var functionBuilder = new GlideDBFunctionBuilder();
var myConcatFunction = functionBuilder.concat();
myConcatFunction = functionBuilder.field('short_description');
```
```javascript
myConcatFunction = functionBuilder.field('caller_id.name');
myConcatFunction = functionBuilder.build();
```

**Scoped GlideDBFunctionBuilder - constant(String constant)**

Defines a constant value to use in the function. If used with the `dayofweek()` method, the string defines whether to use Sunday or Monday as the first day of the week.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>constant</td>
<td>String</td>
<td>A constant value used in a function.</td>
</tr>
</tbody>
</table>

When used with the `dayofweek()` method, the value defines whether the week starts on a Sunday or Monday.

- **1**: Week begins on Sunday.
- **2**: Week begins on Monday.

This definition enables the `dayofweek()` method to return the correct day of the week from a given date. If a value other than 1 or 2 is provided, the `dayofweek()` method uses Sunday as the first day of the week.

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Scoped GlideDBFunctionBuilder - datediff()**

Determines the duration using a given start date/time and end date/time.

Use the `field(String field)` method to define start and end date/time fields.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var functionBuilder = new GlideDBFunctionBuilder();
var myDateDiffFunction = functionBuilder.datediff();
myDateDiffFunction = functionBuilder.field('sys_updated_on');
myDateDiffFunction = functionBuilder.field('opened_at');
myDateDiffFunction = functionBuilder.build();
```

Scoped GlideDBFunctionBuilder - dayofweek()

Returns an integer representing the day of the week for a given date.

Use the `field(String field)` method to define the given date/time. Use the `constant(String constant)` method to define whether the week starts on a Sunday or Monday.

This method can be used with MySQL, Oracle, and Microsoft SQL Server databases only. If using an Oracle database, the NLS_TERRITORY setting must be set to a territory with Sunday as the first day of the week.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td></td>
</tr>
</tbody>
</table>

If the first day of the week is set to Sunday in the `constant(String constant)` method, return values are associated with the following days of the week:

- 1: Sunday
- 2: Monday
- 3: Tuesday
- 4: Wednesday
- 5: Thursday
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• 6</td>
<td>Friday</td>
</tr>
<tr>
<td>• 7</td>
<td>Saturday</td>
</tr>
</tbody>
</table>

If the first day of the week is set to Monday:

| • 1  | Monday      |
| • 2  | Tuesday     |
| • 3  | Wednesday   |
| • 4  | Thursday    |
| • 5  | Friday      |
| • 6  | Saturday    |
| • 7  | Sunday      |

If a value other than 1 or 2 is provided in the `constant(String constant)` method, the `dayOfWeek()` method uses Sunday as the first day of the week.

```javascript
var functionBuilder = new GlideDBFunctionBuilder();
var dayOfWeekFunction = functionBuilder.dayOfWeek();
dayOfWeekFunction = functionBuilder.field('opened_at');
dayOfWeekFunction = functionBuilder.constant('2');
dayOfWeekFunction = functionBuilder.build();

var now_GR = new GlideRecord('incident');
now_GR.addFunction(dayOfWeekFunction);
now_GR.query();
while(now_GR.next())
gs.log(now_GR.getValue(dayOfWeekFunction));
```

**Scoped GlideDBFunctionBuilder - divide()**

Divides the value of one integer field by another.

Use the `field(String field)` method to define fields on which the operation is performed.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var functionBuilder = new GlideDBFunctionBuilder();
var myDivideFunction = functionBuilder.divide();
myDivideFunction = functionBuilder.field('order');
myDivideFunction = functionBuilder.field('priority');
myDivideFunction = functionBuilder.build();
```

**Scoped GlideDBFunctionBuilder - field(String field)**

Defines a field on which a SQL operation is performed.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>The field on which you are performing the SQL operation.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var functionBuilder = new GlideDBFunctionBuilder();
var myAddingFunction = functionBuilder.add();
myAddingFunction = functionBuilder.field('order');
myAddingFunction = functionBuilder.field('priority');
myAddingFunction = functionBuilder.build();
```

**Scoped GlideDBFunctionBuilder - GlideDBFunctionBuilder()**

Instantiates a GlideDBFunctionBuilder object.
### Scoped GlideDBFunctionBuilder - length()

Determines the number of code units in a field.

Use the `field(String field)` method to define fields on which the operation is performed.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

```javascript
define GlideDBFunctionBuilder()

Scoped GlideDBFunctionBuilder - length()

void functionBuilder = GlideDBFunctionBuilder();
definition myLengthFunction = functionBuilder.length();
definition myLengthFunction = functionBuilder.field('short_description');
definition myLengthFunction = functionBuilder.build();
```

### Scoped GlideDBFunctionBuilder - multiply()

Multiplies the values of two integer fields.

Use the `field(String field)` method to define fields on which the operation is performed.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
<tr>
<td>Returns</td>
</tr>
<tr>
<td>---------</td>
</tr>
<tr>
<td>Type</td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

```javascript
var functionBuilder = new GlideDBFunctionBuilder();
var myMultiplyFunction = functionBuilder.multiply();
myMultiplyFunction = functionBuilder.field('order');
myMultiplyFunction = functionBuilder.field('priority');
myMultiplyFunction = functionBuilder.build();
```

**Scoped GlideDBFunctionBuilder - subtract()**

Subtracts the value of one integer field from another.

Use the `field(String field)` method to define fields on which the operation is performed.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

```javascript
var functionBuilder = new GlideDBFunctionBuilder();
var mySubtractFunction = functionBuilder.subtract();
mySubtractFunction = functionBuilder.field('order');
mySubtractFunction = functionBuilder.field('priority');
mySubtractFunction = functionBuilder.build();
```

**GlideDialogWindow - Client**

The GlideDialogWindow API provides methods for displaying a dialog in the current window and frame.
Use these methods in scripts anywhere that you can use a client-side JavaScript. These methods are most often called from a UI action with the Client check box selected.

💡 Note: This API has been deprecated, use the GlideModalV3 API instead.

GlideDialogWindow - adjustBodySize()

Adjusts the body height of a dialog window to be the window height minus the header height.

You typically call this method after calling GlideDialogWindow - setSize().

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

```javascript
var gdw = new GlideDialogWindow('show_list');
gdw.setTitle('Test');
gdw.setSize(750,300);
gdw.adjustBodySize();
gdw.render();
```

GlideDialogWindow - destroy()

Closes the dialog window.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>
GlideDialogWindow - GlideDialogWindow(String id, Boolean readOnly, Number width, Number height)

Provides methods for displaying a dialog in the current window and frame.

Use these methods in scripts anywhere that you can use a client-side JavaScript. These methods are most often called from a UI Action with the **Client** check box selected.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>Name of the UI page to load into the dialog window.</td>
</tr>
<tr>
<td>readOnly</td>
<td>Boolean</td>
<td>Optional. Flag that indicates whether the dialog window is read only (true) or read/write (false). Default: false</td>
</tr>
<tr>
<td>width</td>
<td>Number</td>
<td>Optional. Size (in pixels) to set the width of the dialog window.</td>
</tr>
<tr>
<td>height</td>
<td>Number</td>
<td>Optional. Size (in pixels) to set the height of the dialog window.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
//Destroy the current dialog window.
GlideDialogWindow.get().destroy();
```

```java
// Creates a dialog window
var gdw = new GlideDialogWindow('show_list');
```

```java
// Creates a read-only dialog window
var gdw = new GlideDialogWindow('show_list', true);
```
// Creates a dialog window that is 400 pixels wide
var gdw = new GlideDialogWindow('show_list', false, 400);

// Creates a dialog window that is 400 pixels wide and 200 pixels tall
var gdw = new GlideDialogWindow('show_list', false, 400, 200);

**GlideDialogWindow - render()**
Renders the dialog window.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```
var gdw = new GlideDialogWindow('show_list');
gdw.setTitle('Test');
gdw.setSize(750,300);
gdw.setPreference('table', 'u_test_list');
gdw.setPreference('title', 'A New Title');
gdw.render();
```

**GlideDialogWindow - removeCloseDecoration()**
Removes the close decoration in the upper right corner of the window.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
// Remove the close decoration from the current dialog window.
GlideDialogWindow.get().removeCloseDecoration();

GlideDialogWindow - setPreference(String name, String value)
Sets a given window property to a specified value.
Any window property can be set using this method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The window property to set.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The value for the window property.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdw = new GlideDialogWindow('show_list');
gdw.setTitle('Test');
gdw.setSize(750,300);
gdw.setPreference('table', 'u_test_list');
gdw.setPreference('title', 'A New Title');
```

GlideDialogWindow - setSize(Number width, Number height)
Sets the size of the dialog window.
If you do not pass width and height parameters, a default size is used.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>Number</td>
<td>The width of the dialog window.</td>
</tr>
<tr>
<td>height</td>
<td>Number</td>
<td>The height of the dialog window.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td></td>
</tr>
<tr>
<td>void</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gdw = new GlideDialogWindow('show_list');
gdw.setSize(750, 300);
```

**GlideDialogWindow - setTitle(String title)**

Sets the title of the dialog window.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>String</td>
<td>The title for the current window.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
//var gdw = new GlideDialogWindow('show_list');
gdw.setTitle('test');
```

**GlideDigest - Scoped**

The scoped GlideDigest class provides methods for creating a message digest from strings or input streams using MD5, SHA1, or SHA256 hash algorithms.

**Scoped GlideDigest - getMD5Base64(String source)**

Create a message digest from a string using the MD5 algorithm. The output string is in Base64.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>String</td>
<td>The source string.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>--------</td>
<td>---------------------------</td>
<td></td>
</tr>
<tr>
<td>String</td>
<td>The message digest.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var inputString = "Her molasses flowed slowly down the hill."
var digest = new GlideDigest();
gs.info(digest.getMD5Base64(inputString));
```

**Scoped GlideDigest - getMD5Base64FromInputStream( GlideScriptableInputStream inputStream)**

Create a message digest from an input stream using the MD5 algorithm. The output string is in Base64.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputStream</td>
<td>GlideScriptableInputStream</td>
<td>The source input stream.</td>
</tr>
</tbody>
</table>

```javascript
var inputStream = new GlideSysAttachment().getContentStream(attachmentSysID);
var digest = new GlideDigest();
gs.info(digest.getMD5Base64FromInputStream(inputStream));
```

**Scoped GlideDigest - getMD5Hex(String source)**

Create a message digest from a string using the MD5 algorithm. The output string is in hexadecimal.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>String</td>
<td>The source string.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The message digest.</td>
</tr>
</tbody>
</table>

```javascript
var inputString = "Her molasses flowed slowly down the hill.";
var digest = new GlideDigest();
gs.info(digest.getMD5Hex(inputString));
```

**Scoped GlideDigest - getMD5HexFromInputStream( GlideScriptableInputStream inputStream)**

Create a message digest from an input stream using the MD5 algorithm. The output string is in hexadecimal.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputStream</td>
<td>GlideScriptableInputStream</td>
<td>The source input stream.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The message digest.</td>
</tr>
</tbody>
</table>

```javascript
var inputStream = new GlideSysAttachment().getContentStream(attachmentSysID);
var digest = new GlideDigest();
gs.info(digest.getMD5HexFromInputStream(inputStream));
```

**Scoped GlideDigest - getSHA1Base64(String source)**

Create a message digest from a string using the SHA1 algorithm. The output string is in Base64.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>String</td>
<td>The source string.</td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td>-------</td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td>String</td>
<td>The message digest.</td>
<td></td>
</tr>
</tbody>
</table>

```
var inputString = "Her molasses flowed slowly down the hill.";
var digest = new GlideDigest();
gs.info(digest.getSHA1Base64(inputString));
```

**Scoped GlideDigest - getSHA1Base64FromInputStream( GlideScriptableInputStream inputStream)***

Create a message digest from an input stream using the SHA1 algorithm. The output string is in Base64.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>inputStream</td>
<td>GlideScriptableInputStream</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>String</td>
<td>The message digest.</td>
</tr>
</tbody>
</table>

```
var inputStream = new GlideSysAttachment().getContentStream(attachmentSysID);
var digest = new GlideDigest();
gs.info(digest.getSHA1Base64FromInputStream(inputStream));
```

**Scoped GlideDigest - getSHA1Hex(String source)**

Create a message digest from a string using the SHA1 algorithm. The output string is in hexadecimal.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>source</td>
<td>String</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The message digest.</td>
</tr>
</tbody>
</table>

var inputString = "Her molasses flowed slowly down the hill.";
var digest = new GlideDigest();
gs.info(digest.getSHA1Hex(inputString));

Scoped GlideDigest - getSHA1HexFromInputStream(GlideScriptableInputStream inputStream)

Create a message digest from an input stream using the SHA1 algorithm. The output string is in hexadecimal.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputStream</td>
<td>GlideScriptableInputStream</td>
<td>The source input stream.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The message digest.</td>
</tr>
</tbody>
</table>

var inputStream = new GlideSysAttachment().getContentStream(attachmentSysID);
var digest = new GlideDigest();
gs.info(digest.getSHA1HexFromInputStream(inputStream));

Scoped GlideDigest - getSHA256Base64(String source)

Create a message digest from a string using the SHA256 algorithm. The output string is in Base64.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>String</td>
<td>The source string.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The message digest.</td>
</tr>
</tbody>
</table>

```
var inputString = "Her molasses flowed slowly down the hill.";
var digest = new GlideDigest();
gs.info(digest.getSHA256Base64(inputString));
```

**Scoped GlideDigest - getSHA256Base64FromInputStream( GlideScriptableInputStream inputStream)**

Create a message digest from an input stream using the SHA256 algorithm. The output string is in Base64.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputStream</td>
<td>GlideScriptableInputStream</td>
<td>The source input stream.</td>
</tr>
</tbody>
</table>

```
var inputStream = new GlideSysAttachment().getContentStream(attachmentSysID);
var digest = new GlideDigest();
gs.info(digest.getSHA256Base64FromInputStream(inputStream));
```

**Scoped GlideDigest - getSHA256Hex(String source)**

Create a message digest from a string using the SHA256 algorithm. The output string is in hexadecimal.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>String</td>
<td>The source string.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The message digest.</td>
</tr>
</tbody>
</table>

var inputString = "Her molasses flowed slowly down the hill.";
var digest = new GlideDigest();
gs.info(digest.getSHA256Hex(inputString));

Scoped GlideDigest -
getSHA256HexFromInputStream(GlideScriptableInputStream inputStream)
Create a message digest from an input stream using the SHA256 algorithm. The output string is in hexadecimal.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputStream</td>
<td>GlideScriptableInputStream</td>
<td>The source input stream.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The message digest.</td>
</tr>
</tbody>
</table>

var inputStream = new GlideSysAttachment().getContentStream(attachmentSysID);
var digest = new GlideDigest();
gs.info(digest.getSHA256HexFromInputStream(inputStream));

Scoped GlideDigest - GlideDigest()
Creates an instance of scoped GlideDigest.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
GlideDocumentV3 - Client

The GlideDocument class provides the ability to search a DOM element, a document, or a JQuery element.

The GlideDocumentV3 API can be used in client-side scripts using ListV2 and ListV3 APIs. The GlideDocument APIs are accessed using the g_document global object.

GlideDocumentV3 - getElement(String selector, Element context)

Returns a node found in the specified DOM based context or created from the HTML context.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>selector</td>
<td>String or Object</td>
<td>Selector expression</td>
</tr>
<tr>
<td>context</td>
<td>String or Object</td>
<td>Optional. DOM Element, document, or JQuery object to search.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node</td>
<td>Node that matches the selector.</td>
</tr>
</tbody>
</table>

This example shows how to get the list view name value from a UI page.

```javascript
// HTML entry
<input type="hidden" id="list_view" name="list_view" value="${sysparm_list_view}" />

// Client script
var listView = g_document.getElementById('#list_view').value;
```

GlideDocumentV3 - getElements(String selector, Element context)

Returns a node list found in the specified DOM based context or created if an HTML context is specified.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>selector</td>
<td>String or Object</td>
<td>The selector expression</td>
</tr>
<tr>
<td>context</td>
<td>String or Object</td>
<td>(Optional) A DOM Element, document, or JQuery object to be searched.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node list</td>
<td>A list of nodes that matches the selector.</td>
</tr>
</tbody>
</table>

### GlideDuration - Scoped

The GlideDuration class provides methods for working with spans of time known as durations.

GlideDuration objects store the duration as the number of days and time from January 1, 1970, 00:00:00. As a result, `setValue()` and `getValue()` use the scoped GlideDateTime object for parameters and return values.

#### Scoped GlideDuration - add(GlideDuration duration)

Adds the duration of the specified GlideDuration object to the current GlideDuration object.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>duration</td>
<td>GlideDuration</td>
<td>GlideDuration object that contains the duration value to add to the current GlideDuration object.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDuration</td>
<td>New GlideDuration object whose duration is the sum of the durations of the two GlideDuration objects.</td>
</tr>
</tbody>
</table>

```javascript
var duration = new GlideDuration('3 12:00:00');
var duration2 = new GlideDuration('3:00:00');
```
```javascript
var answer = duration.add(duration2);
gs.info(answer.getDisplayValue());
```

Output

3 Days 15 Hours

**Scoped GlideDuration - getByFormat(String format)**

Returns the duration value in the specified format.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>String</td>
<td>Duration format. Format: <a href="https://docs.servicenow.com/t%D0%BC%D0%B5%D0%B6%D0%B4%D1%83a/8.2/content/ux-sdk-development-guide.html">Global date and time field format</a></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Current duration in the specified format.</td>
</tr>
</tbody>
</table>

```javascript
var dur = new GlideDuration('3 22:00:00');
gs.info(dur.getByFormat('HH:mm'));
```

Output

22:00

**Scoped GlideDuration - getDayPart()**

Returns the number of days.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td>Number</td>
<td>Number of days in the duration.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var dur = new GlideDuration('3 12:00:00');
gs.info(dur.getDayPart());
```

**Output**

| 3 |

**Scoped GlideDuration - getDisplayValue()**

Returns the display value of the duration in number of days, hours, and minutes.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Number of days, hours, and minutes, such as 2 Days 10 Hours 36 Minutes.</td>
</tr>
<tr>
<td></td>
<td>Format: Display value: &quot;n&quot; Days &quot;n&quot; Hours &quot;n&quot; Minutes</td>
</tr>
</tbody>
</table>

```javascript
var dur = new GlideDuration('3 12:00:00');
gs.info(dur.getDisplayValue());
```

**Output**

| 3 Days 12 Hours |

**Scoped GlideDuration - GlideDuration()**

Instantiates a GlideDuration object.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Scoped GlideDuration - getDurationValue()

Returns the duration value in "d HH:mm:ss" format.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Duration value. Format: d HH:mm:ss where &quot;d&quot; is number of days.</td>
</tr>
</tbody>
</table>

```javascript
var dur = new GlideDuration(60000);
gs.info(dur.getDurationValue());
```

Output

00:01:00

Scoped GlideDuration - getRoundedDayPart()

Returns the rounded number of days. If the time part is more than 12 hours, the return value is rounded up. Otherwise, it is rounded down.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Day value of the display value rounded.</td>
</tr>
</tbody>
</table>

```javascript
var dur = new GlideDuration('3 14:00:00');
gs.info(dur.getRoundedDayPart());
```

Output

4

Scoped GlideDuration - getValue()

Returns the internal date/time value of the current GlideDuration object.

GlideDuration objects store the duration as a date and time from January 1, 1970, 00:00:00.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Current duration within the GlideDuration object.</td>
</tr>
<tr>
<td></td>
<td>Format: YYYY-MM-DD HH:mm:ss</td>
</tr>
</tbody>
</table>

```javascript
var dur = new GlideDuration('3 12:00:00');
gs.info(dur.getValue());
```

Output:

1970-01-04 12:00:00

Scoped GlideDuration - GlideDuration(GlideDuration another)

Instantiates a GlideDuration object by cloning the values of the passed in GlideDuration object.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>another</td>
<td>GlideDuration</td>
<td>GlideDuration object.</td>
</tr>
</tbody>
</table>

```javascript
var duration = new GlideDuration('3 12:00:00');
var duration2 = new GlideDuration(duration);
gs.info(duration2.getDisplayValue());
```

**Output**

3 Days 12 Hours

---

### Scoped GlideDuration - GlideDuration(Number milliseconds)

Instantiates a GlideDuration object with the specified duration in milliseconds.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>Duration value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Unit: Milliseconds</td>
</tr>
</tbody>
</table>

```javascript
var dur = new GlideDuration(60000);
gs.info(dur.getDurationValue());
```

**Output**

00:01:00

---

### Scoped GlideDuration - GlideDuration(String displayValue)

Instantiates a GlideDuration object with the specified duration display value.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>displayValue</td>
<td>String</td>
<td>Duration value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Format: d HH:mm:ss where &quot;d&quot; is number of days.</td>
</tr>
</tbody>
</table>

```javascript
var duration = new GlideDuration('3 12:00:00');
var duration2 = new GlideDuration('3:00:00');
```
```javascript
var answer = duration.add(duration2);
gs.info(answer.getDisplayValue());
```

**Output**

```
3 Days 15 Hours
```

### Scoped GlideDuration - setDisplayValue(String asDisplayed)

Sets the duration display value.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asDisplayed</td>
<td>String</td>
<td>Display duration value to set. Format: d HH:mm:ss where &quot;d&quot; is number of days</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var dur = new GlideDuration();
dur.setDisplayValue('3 08:00:00');
gs.info(dur.getDisplayValue());
```

**Output**

```
3 Days 8 Hours
```

### Scoped GlideDuration - setValue(Object o)

Sets the internal date/time value of the GlideDuration object.

The method sets the duration value to the difference of the passed in date/time the base date/time value of January 1, 1970, 00:00:00. The passed in date/time object (string) is parsed into a GlideDateTime object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>o</td>
<td>Object</td>
<td>Date and time to use as the endpoint for the calculated duration time.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Format: YYYY-MM-DD HH:mm:ss</td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var dur = new GlideDuration();
dur.setValue('1970-01-05 08:00:00'); // sets internal DateTime value. The String is parsed into a GlideDateTime object.
gs.info(dur.getDisplayValue());
```

Output:

```
4 Days 8 Hours
```

**Scoped GlideDuration - subtract(GlideDuration duration)**

Subtracts the duration of the specified GlideDuration object to the current GlideDuration object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>duration</td>
<td>GlideDuration</td>
<td>GlideDuration object that contains the duration value to subtract from the current GlideDuration object.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDuration</td>
<td>New GlideDuration object whose duration contains the result of the subtraction of the duration of the two GlideDuration objects.</td>
</tr>
</tbody>
</table>

```javascript
var duration = new GlideDuration('3 12:00:00');
var duration2 = new GlideDuration('3:00:00');
var answer = duration.subtract(duration2);
gs.info(answer.getDisplayValue());
```
Output:

3 Days 9 Hours

**GlideElement - Global**

The GlideElement API provides a number of convenient script methods for dealing with fields and their values. GlideElement methods are available for the fields of the current GlideRecord.

**GlideElement - canCreate()**

Determines if the user's role permits the creation of new records in this field.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Boolean</td>
</tr>
</tbody>
</table>

**Scoped equivalent**

To use the canCreate() method in a scoped application, use the corresponding scoped method: **Scoped GlideElement - canCreate()**.

**GlideElement - canRead()**

Determines whether the user’s role permits them to read the associated GlideRecord.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the field can be read, false otherwise.</td>
</tr>
</tbody>
</table>

### Scoped equivalent

To use the `canRead()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - canRead()`.

### GlideElement - canWrite()

Determines whether the user's role permits them to write to the associated GlideRecord.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the user can write to the field, false otherwise.</td>
</tr>
</tbody>
</table>

### Scoped equivalent

To use the `canWrite()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - canWrite()`.

### GlideElement - changes()

Determines if the current field has been modified. This functionality is available for all available data types, except Journal fields.

> **Note:** The `changes()` method is not supported within ACL scripts.

> **Note:** If the GlideRecord on which you are performing this method has only been initialized and read, and has not been written, the underlying before-and-after values are the same. In this case, the method returns "false", as there has been no change to the data store.
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the field has changed, false otherwise.</td>
</tr>
</tbody>
</table>

**Scoped equivalent**

To use the `changes()` method in a scoped application, use the corresponding scoped method: **Scoped GlideElement - changes()**.

**GlideElement - changesFrom(Object value)**

Determines if the previous value of the current field matches the specified object.

⚠️ **Note:** If the GlideRecord on which you are performing this method has only been initialized and read, and has not been written, the underlying before-and-after values are the same. In this case, the method returns "false", as there has been no change to the data store.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Object</td>
<td>An object value to check against the previous value of the current field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the previous value matches the parameter, false if it does not.</td>
</tr>
</tbody>
</table>

```java
if (theState.changesTo(resolvedState)) {
    operation = 4; //Resolved
}
else if (theState.changesTo(closedState)) {
```
operation = 11; //Resolution Accepted
} else if (theState.changesFrom(resolvedState) || theState.changesFrom(closedState)) {
    operation = 10; //Re-open
} else {
    operation = 6; //Update
}

### Scoped equivalent

To use the `changesFrom()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - changesFrom(Object o)`.

### GlideElement - changesTo(Object value)

Determines if the new value of a field, after a change, matches the specified object.

> **Note:** The `changesTo()` method is not supported within ACL scripts.

> **Note:** If the GlideRecord on which you are performing this method has only been initialized and read, and has not been written, the underlying before-and-after values are the same. In this case, the method returns “false”, as there has been no change to the data store.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Object</td>
<td>An object value to check against the new value of the current field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the new value matches the parameter, false if it does not.</td>
</tr>
</tbody>
</table>

if (theState.changesTo(resolvedState)) {
    operation = 4; //Resolved
} else if (theState.changesTo(closedState)) {

operation = 11; //Resolution Accepted
}

else if (theState.changesFrom(resolvedState) || theState.changesFrom(closedState)) {
    operation = 10; //Re-open
}
else {
    operation = 6; //Update
}

Scoped equivalent

To use the changesTo() method in a scoped application, use the corresponding scoped method: Scoped GlideElement - changesTo(Object o).

GlideElement - dateNumericValue()

Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT for a duration field. Does not require the creation of a GlideDateTime object because the duration field is already a GlideDateTime object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of milliseconds since January 1, 1970, 00:00:00 GMT.</td>
</tr>
</tbody>
</table>

var inc = new GlideRecord('incident');
inc.get('17c90efb13418700cc36b1422244b05d');
gs.info(inc.calendar_duration.dateNumericValue());

Output: 98000

Scoped equivalent

To use the dateNumericValue() method in a scoped application, use the corresponding scoped method: Scoped GlideElement - dateNumericValue().
**GlideElement - debug(Object o)**

Debugs the object and adds debug messages using `setError(String)`.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>o</td>
<td>Object</td>
<td>An object to debug.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideElement - getAttribute(String attributeName)**

Returns the value of the specified attribute from the dictionary.

If the attribute is a boolean attribute, use `getBooleanAttribute(String)` to get the value as a boolean rather than as a string.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributeName</td>
<td>String</td>
<td>Attribute name</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Attribute value</td>
</tr>
</tbody>
</table>

```javascript
function doit() {
  var now_GR = new GlideRecord('sys_user');
  now_GR.query("user_name","admin");
  if (now_GR.next()) {
    gs.print("we got one");
    gs.print(now_GR.location.getAttribute("tree_picker"));
  }
}
```
Scoped equivalent

To use the `getAttribute()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - getAttribute(String attributeName)`.

`GlideElement - getBaseTableName()`

Gets the base table of the field.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

`GlideElement - getBooleanAttribute(String attributeName)`

Returns the Boolean value of the specified attribute from the dictionary.

To get the value as a string, use `getAttribute(string)`.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>attributeName</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Boolean</td>
</tr>
</tbody>
</table>
Scoped equivalent

To use the `getBooleanAttribute()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - getBooleanAttribute(String attributeName)`.

GlideElement - `getChoices(String value)`

Generates a choice list for a field. Returns the choice values from the base table only, not from the extended table.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>An optional dependent value.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>array list</td>
<td>The choice values for the field.</td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the `getChoices()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - getChoices(String dependent)`.

GlideElement - `getChoiceValue()`

Gets the choice label for the current choice value.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The choice label.</td>
</tr>
</tbody>
</table>
Scoped equivalent

To use the `getChoiceValue()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - getChoiceValue()`.

GlideElement - `getDebugCount()`

Gets the number of debug messages logged by `debug()`.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Number</td>
</tr>
</tbody>
</table>

GlideElement - `getDependent()`

Checks whether or not the field is dependent on another field.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

GlideElement - `getDependentTable()`

Gets the table that the current table depends on.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The name of the table.</td>
</tr>
</tbody>
</table>

**GlideElement - getDisplayValue(Number maxChar)**

Gets the formatted display value of the field.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxChar</td>
<td>Number</td>
<td>Optional, maximum number of characters to return.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Display value of the field.</td>
</tr>
</tbody>
</table>

```javascript
var fields = current.getFields();
for (var i = 0; i < fields.size(); i++) {
    var field = fields.get(i);
    var name = field.getName();
    var value = field.getDisplayValue();
    gs.print(i + ". " + name + "=" + value);
}
```

**Scoped equivalent**

To use the `getDisplayValue()` method in a scoped application, use the corresponding scoped method: **Scoped GlideElement - getDisplayValue(Number maxCharacters)**.
GlideElement - getDisplayValueExt(Number maxChar, String nullSub)

Gets the formatted display value of a field, or a specified substitute value if the display value is null or empty.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxChar</td>
<td>Number</td>
<td>Optional, the maximum number of characters to be returned.</td>
</tr>
<tr>
<td>nullSub</td>
<td>String</td>
<td>The value to return if the display value is null or empty.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The formatted display value of the field, or the specified substitute value.</td>
</tr>
</tbody>
</table>

GlideElement - getED()

Returns an element descriptor, which provides information about specific fields, rather than the data inside of those fields.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ElementDescriptor</td>
<td>The field's element descriptor.</td>
</tr>
</tbody>
</table>

This example gets the fields and field descriptors for the current record.

```javascript
var fields = current.getFields();
for (i=0; i<fields.size(); i++) {
    var field = fields.get(i);
    var descriptor = field.getED();
    gs.print("type=" + descriptor.getType() + " name=" + descriptor.getName());
```
Scoped equivalent

To use the `getED()` method in a scoped application, use the corresponding scoped method: **Scoped GlideElement - getED().**

GlideElement - `getElementValue(String value)`

Returns the value for the specified element.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>Element whose value you want returned.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value of the element.</td>
</tr>
</tbody>
</table>

```javascript
var fields = current.getFields();
for (var i = 0; i < fields.size(); i++) {
    var field = fields.get(i);
    var name = field.getName();
    // Returns the unformatted value of the element
    var value = field.getElementValue(name);
    var disValue = field.getDisplayValue();
    gs.print(i + " . " + name + " = " + value + ' display value = ' + disValue);
}
```

**Output**

```
1. cmdb_ci = 109562a3c611227500a7b7ff98cc0dc7 display value = Storage Area Network 001
2. impact = 2 display value = 2 - Medium
```

GlideElement - `getError()`

Gets error debug messages.
### GlideElement - getEscapedValue()

Gets the escaped value for the current element.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A string of debug messages</td>
</tr>
</tbody>
</table>

### GlideElement - getFieldStyle()

Gets the CSS style for the field.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The CSS style for the field.</td>
</tr>
</tbody>
</table>
```javascript
var fields = current.getFields();
for (var i = 0; i < fields.size(); i++) {
    var field = fields.get(i);
    var css_style = field.getFieldStyle();
    gs.print("CSS style" + "=" + css_style);
}
```

**GlideElement - getGlideObject()**

Gets a glide object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>A Glide object.</td>
</tr>
</tbody>
</table>

```javascript
function calcDateDelta(start, end, calendar) {
    var cal = GlideCalendar.getCalendar(calendar);
    if (!cal.isValid())
        return null;
    var realStart = start.getGlideObject();
    var realEnd = end.getGlideObject();
    var duration = cal.subtract(realStart, realEnd);
    return duration;
}
```

**GlideElement - getGlideRecord()**

Gets a glide record.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
var grInc = new GlideRecord('incident');
grInc.get('sys_id','ef43c6d40a0a0b5700c77f9bf387afe3');
gs.info("Initial grInc - " + grInc.getDisplayValue());

var caller = grInc.getElementById("caller_id");
doit(caller);

function doit(caller) {
    var now_GR = caller.getGlideRecord();
    gs.info("doit gr is - " + now_GR.getDisplayValue());
}

Output

*** Script: Initial grInc - INC0000050
*** Script: doit gr is - INC0000050

GlideElement - getHTMLValue(Number maxChars)

Returns the HTML value of a field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxChars</td>
<td>Number</td>
<td>Optional. Maximum number of characters to return.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>HTML value for the field.</td>
</tr>
</tbody>
</table>

var inccause = new GlideRecord("incident");
inccause.short_description = current.short_description;
inccause.comments = current.comments.getHTMLValue();
inccause.insert();
Scoped equivalent

To use the `getHTMLValue()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - getHTMLValue(Number maxChars)`.

**GlideElement - getHTMLValueExt(Number maxChar, String nullSub)**
Returns the HTML value of a field, or a specified substitute value if the HTML value is null or empty.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxChar</td>
<td>Number</td>
<td>The maximum number of characters to return.</td>
</tr>
<tr>
<td>nullSub</td>
<td>String</td>
<td>The value to return if the HTML value is null or empty.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The HTML value or the specified substitute value.</td>
</tr>
</tbody>
</table>

**GlideElement - getJournalEntry(Number mostRecent)**
Returns either the most recent journal entry or all journal entries.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mostRecent</td>
<td>Number</td>
<td>If 1, returns the most recent entry. If -1, returns all journal entries.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>For the most recent entry, returns a string that contains the field label, timestamp, and user display name of the journal entry. For all journal entries, returns the same information for all journal entries ever entered as a single string with each entry delimited by &quot;\n\n&quot;.</td>
</tr>
</tbody>
</table>
// gets all journal entries as a string where each entry is delimited by '\n\n'
var notes = current.work_notes.getJournalEntry(-1);
// stores each entry into an array of strings
var na = notes.split("\n\n");

for (var i = 0; i < na.length; i++)
    gs.print(na[i]);

**Scoped equivalent**

To use the `getJournalEntry()` method in a scoped application, use the corresponding scoped method: **Scoped GlideElement - getJournalEntry(Number mostRecent).**

**GlideElement - getLabel()**

Returns the object's label.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Object's label</td>
</tr>
</tbody>
</table>

### Example

```javascript
var now_GR = new GlideRecord("sc_req_item");
now_GR.addQuery("request", current.sysapproval);
now_GR.query();
while(now_GR.next()) {
    var nicePrice = now_GR.price.toString();
    if (nicePrice != ) {
        nicePrice = parseFloat(nicePrice);
        nicePrice = nicePrice.toFixed(2);
    }
    template.print(now_GR.number +": " + now_GR.quantity + " X " +
now_GR.cat_item.getDisplayValue() + " at $" + nicePrice + " each \n");
    template.print(" Options:
");
    var variables = now_GR.variables.getElements();
```
for (var key in variables) {
    var now_V = variables[key];
    if (now_V.getQuestion().getLabel() != ) {
        template.space(4);
        template.print('     ' +  now_V.getQuestion().getLabel() + " = " +
        now_V.getDisplayValue() + "\n");
    }
}

Scoped equivalent
To use the `getLabel()` method in a scoped application, use the corresponding scoped method: **Scoped GlideElement - `getLabel()`**.

**GlideElement - `getName()`**
Returns the name of the field.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

Scoped equivalent
To use the `getName()` method in a scoped application, use the corresponding scoped method: **Scoped GlideElement - `getName()`**.

**GlideElement - `getRefRecord()`**
Returns a GlideRecord object for a given reference element.

⚠️ **Warning:** If the reference element does not contain a value, it returns an empty GlideRecord object, not a NULL object.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>A GlideRecord object</td>
</tr>
</tbody>
</table>

```javascript
var grINC = new GlideRecord('incident');
grINC.notNullQuery('caller_id');
grINC.query();
if (grINC.next()) {

  // Get a GlideRecord object for the referenced sys_user record
  var grUSER = grINC.caller_id.getRefRecord();
  if (grUSER.isValidRecord())
    gs.print( grUSER.getValue('name') );
}
```

Scoped equivalent

To use the `getRefRecord()` method in a scoped application, use the corresponding scoped method: **Scoped GlideElement - getRefRecord()**.

**GlideElement - getStyle()**

Get the CSS style for the value.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The CSS style for the value.</td>
</tr>
</tbody>
</table>
// Get string of style field from Field Style record
var cssStyle = now_GR.state.getStyle();

**GlideElement - getTableName()**

Returns the name of the field's table.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of the table. This may be different from the table Class that the record is in. See Tables and Classes in the product documentation.</td>
</tr>
</tbody>
</table>

```javascript
if (current.approver.getTableName() == "sysapproval_approver") {
    if (current.approver == email.from_sys_id) {
        current.comments = "reply from: " + email.from + "\n\n" + email.body_text;

        // if it's been cancelled, it's cancelled.
        var doit = true;
        if (current.state=='cancelled')
            doit = false;

        if (email.body.state != undefined)
            current.state= email.body.state;

        if (doit)
            current.update();
    } else {
        gs.log("Approval for task ("+current.sysapproval.getDisplayValue()+") rejected because user sending email( "+email.from+") does not match the approver ("+current.approver.getDisplayValue()+")");
    }
}
```
Scoped equivalent

To use the `getTableName()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - getTableName()`.

**GlideElement - getTextAreaDisplayValue()**

Retrieves the value and escapes the HTML.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

**GlideElement - getXHTMLValue()**

Retrieves the XHTML value of a field.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

**GlideElement - getXMLValue()**

Gets the XML value of a field as a string.
<table>
<thead>
<tr>
<th>Parameters</th>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td></td>
<td>The XML value</td>
</tr>
</tbody>
</table>

**GlideElement - hasAttribute(String attributeName)**

Determines whether a field has a particular attribute.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>attributeName</td>
<td>String</td>
<td>The attribute to check for</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td></td>
<td>True if the field has the attribute, false otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var totalCritical = 0;

var filledCritical = 0; var fields = current.getFields(); gs.print(fields); for (var num = 0; num < fields.size(); num++) {
    gs.print("RUNNING ARRAY VALUE " + num);
    var ed = fields.get(num).getED();
    if(ed.hasAttribute("tiaa_critical")) {
        gs.print("CRITICAL FIELD FOUND");
        totalCritical ++;
        if (!fields.get(num).isNil()) {
            filledCritical ++;
        }
    }
}
```
var answer = 0; gs.print("TOTAL = " + totalCritical); gs.print("FILLED = " + filledCritical); if (filledCritical &gt; 0 &amp;&amp; totalCritical &gt; 0) {
    var pcnt = (filledCritical/totalCritical)*100;
    answer = pcnt.toFixed(2);
}

GlideElement - hasRightsTo(String operationName)
Determines if the user has the right to perform a particular operation.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operationName</td>
<td>String</td>
<td>Name of the operation to check for</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the user has permission to perform the operation, false otherwise.</td>
</tr>
</tbody>
</table>

GlideElement - hasValue()
Determines if the field has a value.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the field has a value, false otherwise.</td>
</tr>
</tbody>
</table>

GlideElement - nil()
Determines whether the field is null.
### GlideElement - `setValue(String value)`

Sets the duration field to a value in the duration format. Does not require the creation of a GlideDateTime object because the duration field is already a GlideDateTime object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>Value to set to the duration field</td>
</tr>
</tbody>
</table>

**Returns**

- `void`

```java
if (current.start_date.changes() || current.end_date.changes() ||
    current.assigned_to.changes()) {
    if (!current.start_date.nil() && !current.end_date.nil() && !current.assigned_to.nil()) {
        gs.eventQueue("change.calendar.notify", current, current.assigned_to,
                      previous.assigned_to);
    }
}
```

### Scoped equivalent

To use the `nil()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - nil()`.

### GlideElement - `setDateNumericValue(Number milliseconds)`

Sets the duration field to a number of milliseconds since January 1, 1970, 00:00:00 GMT for a duration field. Does not require the creation of a GlideDateTime object because the duration field is already a GlideDateTime object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>Number of milliseconds spanned by the duration.</td>
</tr>
</tbody>
</table>

**Returns**

- `void`
var inc = new GlideRecord('incident');
inc.get('17c90efb13418700cc36b1422244b05d');
var timems = inc.calendar_duration.dateNumericValue();
timems = timems + 11*1000;
inc.calendar_duration.setDateNumericValue(timems)
gs.info(inc.calendar_duration.getValue());

Output: 1970-01-01 00:01:38

Scoped equivalent

To use the `setDateNumericValue()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - setDateNumericValue(Number milliseconds)`.

**GlideElement - setDisplayValue(Object displayValue)**

Sets the display value of the field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>displayValue</td>
<td>Object</td>
<td>Value to be displayed.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the `setDisplayValue()` method in a scoped application, use the corresponding scoped method: `Scoped GlideElement - setDisplayValue(Object value)`.

**GlideElement - setError(String message)**

Adds an error message.

Can be retrieved using `getError()`.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```java
if (!current.u_date1.nil() && !current.u_date2.nil()) {
    var start = current.u_date1.getGlideObject().getNumericValue();
    var end = current.u_date2.getGlideObject().getNumericValue();
    if (start > end) {
        gs.addInfoMessage('start must be before end');
        current.setAbortAction(true);
        current.u_date1.setError('start must be before end');
    }
}
```

### Scoped equivalent

To use the `setError()` method in a scoped application, use the corresponding scoped method: **Scoped GlideElement - setError(String errorMessage)**.

### GlideElement - setInitialValue(Object value)

Sets the initial value of a field.

This method had been deprecated. Use **GlideElement - setValue(Object value)** for this functionality.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Object</td>
<td>Initial value for the field.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
GlideElement - setJournalEntry(String entry, String userName)

Adds a journal entry and author as a work note or comment field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>entry</td>
<td>String</td>
<td>Content of the journal entry.</td>
</tr>
<tr>
<td>userName</td>
<td>String</td>
<td>Optional. The user to attribute the journal entry to. Does not set the journal entry's created by field.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to add a work note and its author to a record.

```java
var now_GR = new GlideRecord("incident");

now_GR.addQuery("sys_id", "<sys_id_value>");
now_GR.query();

if(now_GR.next()){
    now_GR.work_notes.setJournalEntry("Content of the journal entry.", "abel.tuter");
    now_GR.update();
}
```

GlideElement - setValue(Object value)

Sets the value of a field.

⚠️ **Note:** Before calling this method, the element must already exist by querying an existing record or by using the `now_GR.initialize()` method to initialize a new record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Object</td>
<td>The value the field is to be set to.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>-------</td>
<td>----------------------</td>
<td></td>
</tr>
<tr>
<td>void</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Set the value passing a string.

```javascript
var glideRecord = new GlideRecord('incident');
glideRecord.query('priority','1');
glideRecord.next();
glideRecord.short_description.setValue('Network failure');
```

Set the value passing an object.

```javascript
var now_GR  = new GlideRecord('student');
now_GR.initialize();
now_GR.setValue('first_name', 'Joe');
now_GR.setValue('last_name', 'Smith');
now_GR.insert();
```

**Scoped equivalent**

To use the `setValue()` method in a scoped application, use the corresponding scoped method: **Scoped GlideElement - setValue(Object value)**.

**GlideElement - toString()**

Converts the field's value to a string.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The field's value as a string.</td>
</tr>
</tbody>
</table>

```javascript
doit();
function doit() {
```
var now_GR = new GlideRecord('sys_user');
now_GR.query();
while (now_GR.next()) {
    if ((now_GR().length != now_GR.first_name.toString().trim().length) ||
        (now_GR.last_name.toString().length != now_GR.last_name.toString().trim().length)) {
        now_GR.first_name = now_GR.first_name.toString().trim();
        now_GR.last_name = now_GR.last_name.toString().trim();
        now_GR.autoSysFields(false);
        now_GR.update();
    }
}

Scoped equivalent

To use the toString() method in a scoped application, use the corresponding scoped method: Scoped GlideElement - toString().

GlideElement - Scoped

The Scoped GlideElement API provides a number of convenient script methods for dealing with fields and their values. Scoped GlideElement methods are available for the fields of the current GlideRecord.

Scoped GlideElement - canCreate()

Determines if the user's role permits the creation of new records in this field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the field can be created, false otherwise.</td>
</tr>
</tbody>
</table>
Scoped GlideElement - canRead()
Indicates whether the user's role permits them to read the associated GlideRecord.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the field can be read, false otherwise.</td>
</tr>
</tbody>
</table>

Scoped GlideElement - canWrite()
Determines whether the user's role permits them to write to the associated GlideRecord.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the user can write to the field, false otherwise.</td>
</tr>
</tbody>
</table>

Scoped GlideElement - changes()
Determines if the current field has been modified. This functionality is available for all available data types, except Journal fields.

Note: The `changes()` method is not supported within ACL scripts.

Note: If the GlideRecord on which you are performing this method has only been initialized and read, and has not been written, the underlying before-and-after values are the same. In this case, the method returns "false", as there has been no change to the data store.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the fields have been changed, false if the field has not.</td>
</tr>
</tbody>
</table>

```java
// This method is often used in business rules. The following example shows is from a business rule,
// if "assigned_to" field value is changed, create a event in the EventQueue.
if (!current.assigned_to.nil() && current.assigned_to.changes()) {
    gs.eventQueue('incident.assigned', current, current.assigned_to.getDisplayValue(),
                  previous.assigned_to.getDisplayValue());
}
```

**Scoped GlideElement - changesFrom(Object o)**

Determines if the previous value of the current field matches the specified object.

**Note:** If the GlideRecord on which you are performing this method has only been initialized and read, and has not been written, the underlying before-and-after values are the same. In this case, the method returns "false", as there has been no change to the data store.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>o</td>
<td>Object</td>
<td>An object value to check against the previous value of the current field.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the previous value matches, false if it does not.</td>
</tr>
</tbody>
</table>
// The following example shows that in a business rule, if "active" field is changed from
// true,
// insert a event in the EventQueue.
if (current.active.changesFrom(true)) {
    gs.eventQueue("incident.inactive", current, current.incident_state,
        previous.incident_state);
}

Scoped GlideElement - changesTo(Object o)

Determines if the new value of a field, after a change, matches the specified
object.

⚠️ Note: The changesTo() method is not supported within ACL scripts.

⚠️ Note: If the GlideRecord on which you are performing this method has only
been initialized and read, and has not been written, the underlying before-
and-after values are the same. In this case, the method returns "false", as
there has been no change to the data store.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>o</td>
<td>Object</td>
<td>An object value to check against the new value of the current field.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the previous value matches, false if it does not.</td>
</tr>
</tbody>
</table>

// The following example shows that in a business rule, if "active" field is changed to
false,
// insert a event in the EventQueue.
if (current.active.changesTo(false)) {
    gs.eventQueue("incident.inactive", current, current.incident_state,
        previous.incident_state);
}
Scoped GlideElement - dateNumericValue()

Returns the number of milliseconds since January 1, 1970, 00:00:00 GMT for a duration field. Does not require the creation of a GlideDateTime object because the duration field is already a GlideDateTime object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of milliseconds since January 1, 1970, 00:00:00 GMT.</td>
</tr>
</tbody>
</table>

```javascript
var inc = new GlideRecord('incident');
inc.get('17c90efb13418700cc36b1422244b05d');
gs.info(inc.calendar_duration.dateNumericValue());
```

Output: 98000

Scoped GlideElement - getAttribute(String attributeName)

Returns the value of the specified attribute from the dictionary.

If the attribute is a boolean attribute, use getBooleanAttribute(String) to get the value as a boolean rather than as a string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributeName</td>
<td>String</td>
<td>Attribute name</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Attribute value</td>
</tr>
</tbody>
</table>

```javascript
doit();
function doit() {
```
```javascript
var now_GR = new GlideRecord('sys_user');
now_GR.query("user_name","admin");
if (now_GR.next()) {
    gs.info("we got one");
    gs.info(now_GR.location.getAttribute("tree_picker"));
}
```
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>List of possible values for the choice list, which are the values in the Choice [sys_choice] table. If the dependent parameter is passed, the return results reflect only those choices available for the specified dependent field.</td>
</tr>
</tbody>
</table>

```javascript
var glideRecord = new GlideRecord('incident');
glideRecord.query('priority','1');
glideRecord.next();

// urgency has choice list: 1 - High, 2 - Medium, 3 - Low, with value: 1, 2, 3
var choices = glideRecord.urgency.getChoices();
```

**Scoped GlideElement - getChoiceValue()**

Returns the choice label for the current choice.

A choice has a value (number) and a label (string). This method returns the label.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The selected choice's label.</td>
</tr>
</tbody>
</table>

```javascript
var glideRecord = new GlideRecord('incident');
glideRecord.query('priority','1');
glideRecord.next();

// urgency has choice list: 1 - High, 2 - Medium, 3 - Low, with value: 1, 2, 3
var choiceLabel = glideRecord.urgency.getChoiceValue();
gs.info(choiceLabel);
```
**Scoped GlideElement - getDecryptedValue()**

Returns the clear text value for Password (2 way encrypted) fields in scoped applications.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The clear text password.</td>
</tr>
</tbody>
</table>

```javascript
var tablename = 'xScopedApp_table';
var CI = new GlideRecord(tablename);
CI.addQuery('number', '0001002');
CI.query();
CI.next();

var password = CI.password_field
var decrypted = password.getDecryptedValue();
gs.info(decrypted);
```

**Output:**

`xScopedApp: cleartextpassword`

**Scoped GlideElement - getDisplayValue( Number maxCharacters)**

Gets the formatted display value of the field.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxCharacters</td>
<td>Number</td>
<td>Optional: Maximum characters desired</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The display value of the field</td>
</tr>
</tbody>
</table>

```javascript
var glideRecord = new GlideRecord('incident');
glideRecord.query('priority','1');
glideRecord.next();
gs.info(glideRecord.priority.getDisplayValue());
```

**Scoped GlideElement - getED()**

Returns the field's element descriptor.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scoped GlideElementDescriptor</td>
<td>The field's element descriptor.</td>
</tr>
</tbody>
</table>

```javascript
var grInc = new GlideRecord('incident');
grInc.query('priority', '1');

var field = grInc.getElement('priority');
var ed = field.getED();
```

**Scoped GlideElement - getGlobalDisplayValue()**

Returns the phone number in international format.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>--------</td>
<td>--------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>String</td>
<td>The phone number in international format.</td>
<td></td>
</tr>
</tbody>
</table>

**Scoped GlideElement - getHTMLValue(Number maxChars)**

Returns the HTML value of a field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxChars</td>
<td>Number</td>
<td>Optional. Maximum number of characters to return.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>HTML value for the field.</td>
</tr>
</tbody>
</table>

```javascript
var inccause = new GlideRecord("incident");
inccause.short_description = current.short_description;
inccause.comments = current.comments.getHTMLValue();
inccause.insert();
```

**Scoped GlideElement - getJournalEntry(Number mostRecent)**

Returns either the most recent journal entry or all journal entries.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mostRecent</td>
<td>Number</td>
<td>If 1, returns the most recent entry. If -1, returns all journal entries.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>For the most recent entry, returns a string that contains the field label, timestamp, and user display name of the journal entry.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>For all journal entries, returns the same information for all journal entries ever entered as a single string with each entry delimited by &quot;\n\n&quot;.</td>
</tr>
</tbody>
</table>

```javascript
//gets all journal entries as a string where each entry is delimited by '\n\n'
var notes = current.work_notes.getJournalEntry(-1);
//stores each entry into an array of strings
var na = notes.split("\n\n");

for (var i = 0; i < na.length; i++)
  gs.info(na[i]);
```

 Scoped GlideElement - getLabel()

Returns the object label.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td>None</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Object label</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord("sc_req_item");
now_GR.addQuery("request", current.sysapproval);
now_GR.query();
while(now_GR.next()) {
  var nicePrice = now_GR.price.toString();
  if (nicePrice !== ) {
    nicePrice = parseFloat(nicePrice);
    nicePrice = nicePrice.toFixed(2);
  }
  template.print(now_GR.number + ":  " + now_GR.quantity + " X " +
    now_GR.cat_item.getDisplayValue() + " at $" + nicePrice + " each \n\n");
  template.print("    Options:\n")
```
var variables = now_GR.variables.getElements();
for (var key in variables) {
    var now_V = variables[key];
    if (now_V.getQuestion().getLabel() != ) {
        template.space(4);
        template.print('     ' + now_V.getQuestion().getLabel() + " = " + now_V.getDisplayValue() + "\n");
    }
}

**Scoped GlideElement - getName()**

Returns the name of the field.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Scoped GlideElement - getReferenceTable()**

Gets the table name for a reference element.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td>The table name of the reference</td>
</tr>
</tbody>
</table>
var grINC = new GlideRecord('incident');
grINC.query('number','INC0010041'); // record assignment group assigned to "CAB Approval"
if (grINC.next()) {
    // Get the table name
    var tableName = grINC.assignment_group.getReferenceTable();
    gs.info(tableName);
}

Scoped GlideElement - getRefRecord()
Returns a GlideRecord object for a given reference element.

⚠️ Warning: If the reference element does not contain a value, it returns an empty GlideRecord object, not a NULL object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>A GlideRecord object</td>
</tr>
</tbody>
</table>

var grINC = new GlideRecord('incident');
grINC.addNotNullQuery('caller_id');
grINC.query();
if (grINC.next()) {
    // Get a GlideRecord object for the referenced sys_user record
    var grUSER = grINC.caller_id.getRefRecord();
    if (grUSER.isValidRecord())
        gs.info(grUSER.getValue('name'));
}

Scoped GlideElement - getTableName()
Returns the name of the table on which the field resides.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of the table. The returned value may be different from the table Class that the record is in. See Tables and Classes in the product documentation.</td>
</tr>
</tbody>
</table>

```javascript
if (current.approver.getTableName() == "sysapproval_approver") {
    if (current.approver == email.from_sys_id) {
        current.comments = "reply from: " + email.from + "\n\n" + email.body_text;
        // if it's been cancelled, it's cancelled.
        var doit = true;
        if (current.state=='cancelled')
            doit = false;
    
    if (email.body.state != undefined)
        current.state= email.body.state;
    if (doit)
        current.update();
    } else {
        gs.log("Approval for task ("+current.sysapproval.getDisplayValue()+") rejected because user sending email ("+email.from+") does not match the approver ("+current.approver.getDisplayValue()+");
    }
}
```

Scoped GlideElement - nil()

Determines if a field is null.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the field is null or an empty string, false if not.</td>
</tr>
</tbody>
</table>

```javascript
var glideRecord = new GlideRecord('incident');
glideRecord.query('priority','1');
glideRecord.next();
gs.info(glideRecord.state.nil());
```

### Scoped GlideElement - `setDateNumericValue(Number milliseconds)`

Sets the value of a date/time element to the specified number of milliseconds since January 1, 1970 00:00:00 GMT.

When called, `setDateNumericValue()` automatically creates the necessary GlideDateTime/GlideDate/GlideDuration object, and then sets the element to the specified value.

**Note:** Before calling this method, the element must already exist by querying an existing record or by using the `now_GR.initialize()` method to initialize a new record.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>Number of milliseconds since 1/1/1970</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord("incident");
now_GR.initialize();
now_GR.opened_at.setDateNumericValue(10000);
```
Scoped GlideElement - setDisplayValue(Object value)
Sets the display value of the field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Object</td>
<td>The value to set for the field.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var glideRecord = new GlideRecord('incident');
glideRecord.query('priority','1');
glideRecord.next();

//change the urgency to 3
glideRecord.urgency.setDisplayValue('3 - Low');
gs.info(glideRecord.urgency);
```

Scoped GlideElement - setError(String errorMessage)
Adds an error message. Available in Fuji patch 3.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>errorMessage</td>
<td>String</td>
<td>The error message.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var glideRecord = new GlideRecord('incident');
glideRecord.query('priority','1');
glideRecord.next();
```
**Scoped GlideElement - setPhoneNumber(Object phoneNumber, Boolean strict)**

Sets the field to the specified phone number.

This method is only available on a phone number GlideElement.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>phoneNumber</td>
<td>Object</td>
<td>The phone number to set. This can be in either the international or local format.</td>
</tr>
<tr>
<td>strict</td>
<td>Boolean</td>
<td>When true, specifies that the number specified must match the correct format. When false, the system attempts to correct an improperly formatted phone number.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the value was set.</td>
</tr>
</tbody>
</table>

**Scoped GlideElement - setValue(Object value)**

Sets the value of a field.

⚠️ **Note:** Before calling this method, the element must already exist by querying an existing record or by using the `now_GR.initialize()` method to initialize a new record.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Object</td>
<td>Object value to set the field to.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Set the value passing a string.

```javascript
var glideRecord = new GlideRecord('incident');
glideRecord.query('priority','1');
glideRecord.next();
glideRecord.short_description.setValue('Network failure');
```

Set the value passing an object.

```javascript
var now_GR  = new GlideRecord('student');
now_GR.initialize();
now_GR.setValue('first_name', 'Joe');
now_GR.setValue('last_name', 'Smith');
now_GR.insert();
```

**Scoped GlideElement - toString()**

Converts the value of a GlideRecord field to a string.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value as a string.</td>
</tr>
</tbody>
</table>

```javascript
var glideRecord = new GlideRecord('incident');
glideRecord.query('priority','1');
glideRecord.next();
gs.info(glideRecord.opened_at.toString());
```

**Output**

```
2019-08-31 23:09:51
```
GlideElementCurrency2 - Scoped

The GlideElementCurrency2 API provides methods to perform operations on Foreign Exchange (FX) Currency fields (also known as Currency2) within the current GlideRecord.

This API provides methods that enable you to perform the following:

• Obtain the FX Currency field display string, as entered by the user.
• Obtain the display value of an FX Currency field.
• Obtain the reference currency value of an FX Currency field.
• Obtain the session currency value of an FX Currency field.
• Set the display value of an FX Currency field.

The GlideElementCurrency2 class has no constructor.

Scoped GlideElementCurrency2 - getAsEnteredDisplayValue()

Returns an FX Currency field display string, as entered by the user, from the associated GlideRecord.

For additional information on FX Currency fields, see Setting up and operating FX Currency fields.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Display currency string as entered by the user.</td>
</tr>
</tbody>
</table>

Example

```javascript
var tablename = 'my_currency2_table';
var setcur2 = new GlideRecord(tablename);
setcur2.initialize();
setcur2.currency_2_field.setDisplayValue('JPY;999999.1234');
setcur2.insert();
gs.info('As entered display value: ' + setcur2.currency_2_field.getAsEnteredDisplayValue());
```
Output:

As entered display value: ¥999,999.12

Scoped GlideElementCurrency2 - getDisplayValue()

Returns the display value of an FX Currency field within the associated GlideRecord.

Depending on how the display_value is set in the FX Currency Configuration [fx_configuration] table, the returned value may be the:

- Currency value as entered by the user
- Currency value converted to the session currency (based on the user's locale)
- Currency value converted to the reference currency

For additional information on FX Currency and the configuration table, see Configure FX Currency global settings.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Display currency value</td>
</tr>
</tbody>
</table>

Example

```javascript
var tablename = 'my_FXcurrency_table';
var setcur2 = new GlideRecord(tablename);
setcur2.initialize();
setcur2.currency_2_field.setDisplayValue('JPY;999999.1234');
setcur2.insert();
gs.info('Display Value: ' + setcur2.currency_2_field.getDisplayValue());
```

Output:

Display Value: ¥999,999.12
Scoped GlideElementCurrency2 - getReferenceDisplayValue()

Returns the reference currency value of an FX Currency field within the associated GlideRecord.

Reference currency is the common currency into which all currency values in a field are converted. The currency code that the `getReferenceDisplayValue()` method uses to derive the reference currency is based on the following:

- If an instance record exists, then the method uses the value in the reference_currency field of the FX Currency [fx_currency2_instance] table.
- If an instance record does not exist, then the method uses the reference currency that would be set on the instance record when the instance record is eventually created (in the following order):
  - If set, the `reference_currency` in the FX Currency Configuration [fx_configuration] table.
  - If set, the `reference_currency_source` in the FX Currency Configuration [fx_configuration] table.
  - System default, system reference currency.

For additional information on the values in the FX Currency Configuration [fx_configuration] table, see Setting up and operating FX Currency fields.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Reference currency amount for the associated FX Currency display value.</td>
</tr>
</tbody>
</table>

This example assumes the reference currency code is USD and uses the default conversion rate specified in the FX Currency Configuration [fx_configuration] table. The output will change based on locale.

```javascript
var tablename = 'my_currency2_table';
var setcur2 = new GlideRecord(tablename);
setcur2.initialize();
setcur2.currency_2_field.setDisplayValue('JPY;999999.1234');
```
Scoped GlideElementCurrency2 - getSessionDisplayValue()

Returns the session currency value of the associated FX Currency field within the current GlideRecord.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Currency value converted to the session currency, which is based on the current user's locale.</td>
</tr>
</tbody>
</table>

This example assumes the session locale is language code = eng and country code = USA, and uses the default conversion rate specified in the FX Currency Configuration [fx_configuration] table. The output will change based on locale.

```javascript
var tablename = 'my_currency2_table';
var setcur2 = new GlideRecord(tablename);
setcur2.initialize();
setcur2.currency_2_field.setDisplayValue('JPY;999999.1234');
setcur2.insert();
gs.info('Session display value: ' + setcur2.currency_2_field.getSessionDisplayValue());
```

Output:

Session display value: $8,677.99

Scoped GlideElementCurrency2 - setDisplayValue(String displayValue)

Sets the display value of an FX Currency field with the specified currency value.

For additional information on FX Currency fields, see Setting up and operating FX Currency fields.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>displayValue</td>
<td>String</td>
<td>Value to set in the FX Currency field in the format <code>&lt;currency code&gt;;&lt;currency amount&gt;</code>. You must format the <code>&lt;currency amount&gt;</code> field in the user's locale. For example, if the user's locale is USA/eng, the passed in <code>&lt;currency amount&gt;</code> would be 123.45. If the user's local is FRA/fre, the passed in <code>&lt;currency amount&gt;</code> would be 123,45.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var tablename = 'my_FXcurrency_table';
var setcur2 = new GlideRecord(tablename);
setcur2.initialize();
setcur2.currency_2_field.setDisplayValue('JPY;999,999.1234');
setcur2.insert();
```

**GlideElementDescriptor - Scoped, Global**

The GlideElementDescriptor API provides information about individual fields in a record.

There is no constructor for this class. Use the GlideElement or GlideRecord getED() method to obtain a GlideElementDescriptor object.

**Scoped GlideElementDescriptor - getAttachmentEncryptionType()**

Returns the encryption type used for attachments on the element's table.

This method is for use with the Edge Encryption plugin.

Parameters
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The encryption type used on attachments. Returns null if attachments on the element's table are not being encrypted.</td>
</tr>
</tbody>
</table>

```javascript
var grInc = new GlideRecord('incident');
grInc.query('priority', '1');

var field = grInc.getElementById('priority');
var ed = field.getED();

var isEdge = ed.getAttachmentEncryptionType();
gs.info(isEdge);
```

Output: null

**Scoped GlideElementDescriptor - getEncryptionType()**

Returns the element's encryption type.

This method is for use with the Edge Encryption plugin.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The element's encryption type. Returns null if the element is not encrypted.</td>
</tr>
</tbody>
</table>

```javascript
var grInc = new GlideRecord('incident');
grInc.query('priority', '1');

var field = grInc.getElementById('priority');
var ed = field.getED();
```
sEdge = ed.getEncryptionType();
gs.info(isEdge);

Output: null

Scoped GlideElementDescriptor - getInternalType()
Returns the element's internal data type.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| String    | The element's internal data type. Possible values:  
|           | • boolean  
|           | • char     
|           | • collection  
|           | • conditions  
|           | • date     
|           | • decimal  
|           | • documentation_field  
|           | • domain_id  
|           | • due_date  
|           | • email    
|           | • field_name  
|           | • file_attachment  
|           | • float    
|           | • glide_date  
|           | • glide_date_time  
|           | • glide_duration  
<p>|           | • glide_list  |</p>
<table>

</tbody>
</table>
var grInc = new GlideRecord('incident');
grInc.query('priority', '1');

var field = grInc.getElement('priority');
var ed = field.getED();

var isEdge = ed.getInternalType();
gs.info(isEdge);

Output:

integer

Scoped GlideElementDescriptor - getLabel()

Returns the element's label.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The element's label.</td>
</tr>
</tbody>
</table>

var grInc = new GlideRecord('incident');
grInc.query('priority', '1');

var field = grInc.getElement('priority');
var ed = field.getED();

var isEdge = ed.getLabel();
gs.info(isEdge);

Output: Priority

Scoped GlideElementDescriptor - getLength()

Returns the element's length.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The element's size.</td>
</tr>
</tbody>
</table>

```javascript
var grInc = new GlideRecord('incident');
grInc.query('priority', '1');

var field = grInc.getElement('priority');
var ed = field.getED();

var isEdge = ed.getLength();
gs.info(isEdge);
```

Output: 40

Scoped GlideElementDescriptor - getName()

Returns the element's name.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The element's name.</td>
</tr>
</tbody>
</table>

```javascript
var grInc = new GlideRecord('incident');
grInc.query('priority', '1');

var field = grInc.getElement('priority');
var ed = field.getED();
```
var isEdge = ed.getName();
gs.info(isEdge);

Output: priority

**Scoped GlideElementDescriptor - getPlural()**

Returns the element's plural label.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The element's plural label.</td>
</tr>
</tbody>
</table>

var now_GR = new GlideRecord('incident');
now_GR.query();
var ed = now_GR.getED();
gs.info(ed.getPlural());

Output: Incidents

**Scoped GlideElementDescriptor - hasAttachmentsEncrypted()**

Returns true if an encrypted attachment has been added to the table.

This method is for use with the Edge Encryption plugin.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if an encrypted attachment has been added to the table.</td>
</tr>
</tbody>
</table>

```javascript
var grInc = new GlideRecord('incident');
grInc.query('priority', '1');

var field = grInc.getElement('priority');
var ed = field.getED();

var isEdge = ed.hasAttachmentsEncrypted();
gs.info(isEdge);
```

Output: false

**Scoped GlideElementDescriptor - isAutoOrSysID()**

Returns true if the element is an automatically generated or system field.

Automatically generated and system fields cannot be encrypted. This method is for use with the Edge Encryption plugin.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the element is automatically generated or a system field.</td>
</tr>
</tbody>
</table>

```javascript
var grInc = new GlideRecord('incident');
grInc.query('priority', '1');
var field = grInc.getElement('priority');
var ed = field.getED();

isEdge = ed.isAutoOrSysID();
gs.info(isEdge);
```
Output: false

Scoped GlideElementDescriptor - isChoiceTable()

Returns true if the element is defined as a dropdown choice in its dictionary definition.

Choice fields cannot be encrypted.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if the element is defined as a dropdown choice. Returns true even if there are no entries defined in the choice table. The last choice type, suggestion, does not return true.</td>
</tr>
</tbody>
</table>

```javascript
var grInc = new GlideRecord('incident');
grInc.query('priority', '1');
var field = grInc.getElementById('priority');
var ed = field.getED();
var isChoiceTable = ed.isChoiceTable();
gs.info(isChoiceTable);
```

Output: true

Scoped GlideElementDescriptor - isEdgeEncrypted()

Returns true if an element is encrypted.

This method is for use with the Edge Encryption plugin.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if the element is encrypted, false otherwise.</td>
</tr>
</tbody>
</table>

```javascript
var grInc = new GlideRecord('incident');
grInc.query('priority', '1');

var field = grInc.getElement('priority');
var ed = field.getED();

var isEdge = ed.isEdgeEncrypted();
gs.info(isEdge)
```

Output: false

**Scoped GlideElementDescriptor - isMandatory()**

Determines whether the element is mandatory and must contain a value before the record can be saved.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean   | Flag that indicates whether the associated element is mandatory and must contain a value before the record containing the element can be saved. Valid values:  
• true: element must contain a value; mandatory field  
• false: element does not have to contain a value |

This example shows how to check whether the name field is mandatory.

```javascript
var isRecordValid;
var now_GR = new GlideRecord('my_table');
```
```javascript
var field = now_GR.getElement('name');
var elementDescriptor = field.getED();
now_GR.query();
while (now_GR.next()) {
  if (elementDescriptor.isMandatory() && !now_GR.name) {
    isRecordValid = false;
  }
}
```

### Scoped GlideElementDescriptor - isVirtual()

Returns true if the element is a virtual element.

A virtual element is a calculated field as set by the dictionary definition of the field. Virtual fields cannot be encrypted.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if the element is a virtual element.</td>
</tr>
</tbody>
</table>

```javascript
var grInc = new GlideRecord('incident');
grInc.query('priority', '1');

var field = grInc.getElement('priority');
var ed = field.getED();

var isVirtual = ed.isVirtual();
gs.info(isVirtual);
```

Output: false

### GlideEmailOutbound - Scoped

The scoped GlideEmailOutbound class implements the email object for scoped applications. You can use the GlideEmailOutbound methods with the email global object available in mail scripts. The email object behaves identically for global and scoped applications.
Scoped GlideEmailOutbound - addAddress(String type, String address)

Adds the address to either the cc or bcc list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>Either cc or bcc, determines the list to which the address is added.</td>
</tr>
<tr>
<td>address</td>
<td>String</td>
<td>The recipient's email address.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

email.addAddress('cc', 'joe.employee@something.com');

Scoped GlideEmailOutbound - addAddress(String type, String address, String displayName)

Adds the recipient to either the cc or bcc list, but uses the display name instead of the address when showing the recipient.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>Either cc or bcc, determines the list to which the address is added.</td>
</tr>
<tr>
<td>address</td>
<td>String</td>
<td>The recipient's email address.</td>
</tr>
<tr>
<td>displayName</td>
<td>String</td>
<td>The name to be shown instead of the email address.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
Scoped GlideEmailOutbound - getSubject()

Returns the email's subject line.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The email's subject line.</td>
</tr>
</tbody>
</table>

Scoped GlideEmailOutbound - getWatermark()

Returns the email's watermark.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The email's watermark.</td>
</tr>
</tbody>
</table>

var watermark = email.getWatermark();

Scoped GlideEmailOutbound - GlideEmailOutbound()

Instantiates a scoped GlideEmailOutbound object.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Scoped GlideEmailOutbound - setBody(String bodyText)
Sets the body of the email.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bodyText</td>
<td>String</td>
<td>The body of the email.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

email.setBody('Dear Sir, ...');

Scoped GlideEmailOutbound - setFrom(String address)
Sets the sender’s address.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>String</td>
<td>The sender’s email address.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

eemail.setFrom('joe.employee@something.com');
Scoped GlideEmailOutbound - setReplyTo(String address)

Sets the reply to address.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>String</td>
<td>The reply to email address.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
eemail.setReplyTo('joe.employee@something.com');
```

Scoped GlideEmailOutbound - setSubject(String subject)

Sets the email's subject line.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subject</td>
<td>String</td>
<td>Text for the subject line.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
eemail.setSubject('Important Issues to discuss');
```

GlideEncrypter - Global

GlideEncrypter provides methods to encrypt and decrypt strings using the Triple DES algorithm.

The GlideEncrypter class is used in server scripts in the global scope. The GlideEncrypter class has two constructors:
• GlideEncrypter()
• GlideEncrypter(String key)

GlideEncrypter - decrypt(String encryptedString)
Decrypts a clear string using the Triple DES algorithm.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encryptedString</td>
<td>String</td>
<td>String to be decrypted.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Clear text string.</td>
</tr>
</tbody>
</table>

```javascript
var encr = new GlideEncrypter();
var clearString = 'abcdefg';
var encrString = encr.encrypt(clearString);
var decrString = encr.decrypt(encrString);
gs.print("Decrypted string = " + decrString);
```

Output:
Decrypted string = abcdefg

GlideEncrypter - encrypt(String clearString)
Encrypts a clear string using the Triple DES algorithm.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clearString</td>
<td>String</td>
<td>String to be encrypted.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Encrypted string.</td>
</tr>
</tbody>
</table>
```javascript
var encr = new GlideEncrypter();
var clearString = 'abcdefg';
var encrString = encr.encrypt(clearString);
gs.print("Encrypted string = " + encrString);

Output:

Encrypted string = 3wjpvKtUIi4=
```

**GlideEncrypter - GlideEncrypter()**

Creates an instance of the GlideEncrypter class using a default (static) encryption key.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var encr = new GlideEncrypter();
```

**GlideEncrypter - GlideEncrypter(String key)**

Creates an instance of the GlideEncrypter class using a given encryption key.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Your encryption key must be exactly 24 characters. A key longer than 24 characters will be truncated.</td>
</tr>
</tbody>
</table>

```javascript
var encr = new GlideEncrypter(myKey);
```

**GlideScopedEvaluator - Global**

The GlideScopedEvaluator API allows you to evaluate scripts in a GlideRecord field from both scoped and global server scripts.

The GlideScopedEvaluator API evaluates scripts within the script field type. The scope of the record defines the scope of the script.
GlideScopedEvaluator - evaluateScript(GlideRecord grObj, String scriptField, Object variables)
Evaluates a script from a GlideRecord field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grObj</td>
<td>GlideRecord</td>
<td>The GlideRecord containing a script expression.</td>
</tr>
<tr>
<td>scriptField</td>
<td>String</td>
<td>(Optional) The name of the field containing the script expression.</td>
</tr>
<tr>
<td>variables</td>
<td>Object</td>
<td>(Optional) A map of variables with name-value pairs. These variables are available to the script during execution of this method.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The result of the script execution.</td>
</tr>
</tbody>
</table>

```
//For this example, we created a table: "x_app_table" with two columns:
//"short_description", "test_script"
//"test_script" will store the script to be evaluated by GlideScopedEvaluator.
var now_GR = new GlideRecord('x_app_table');
now_GR.short_description = 'Testing GlideScopedEvaluator';
now_GR.test_script = "gs.getUser().getName() + ' says ' + greeting; ";
now_GR.insert();

//setup variables to be used by the script
var vars = {'greeting' : 'hello'};

//Evaluate the script from the field
var evaluator = new GlideScopedEvaluator();
gs.info(evaluator.evaluateScript(now_GR, 'test_script', vars));

// Now retrieve the result
evaluator.evaluateScript(gr, 'u_test_script', null);
gs.info(evaluator.getVariable('result'));
```

Output: admin says hello
Scoped equivalent

To use the `evaluateScript()` method in a scoped application, use the corresponding scoped method: `GlideScopedEvaluator - evaluateScript(GlideRecord grObj, String scriptField, Object variables)`.

**GlideScopedEvaluator - getVariable(String name)**

Returns a variable from a GlideScopedEvaluator object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the variable.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The value of the specified variable.</td>
</tr>
</tbody>
</table>

```javascript
//setting up a record that contains the script to be executed.
var now_GR = new GlideRecord('u_global_table');
now_GR.u_short_description = 'Calculate Addition';
now_GR.u_test_script = "result = x + y";
now_GR.insert();

var evaluator = new GlideScopedEvaluator();
evaluator.putVariable('x', 100);
evaluator.putVariable('y', 200);
evaluator.putVariable('result', null);

Output: 300
```

Scoped equivalent

To use the `getVariable()` method in a scoped application, use the corresponding scoped method: `GlideScopedEvaluator - getVariable(String name)`.

**GlideScopedEvaluator - GlideScopedEvaluator()**

Instantiates a GlideScopedEvaluator object.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the GlideScopedEvaluator() method in a scoped application, use the corresponding scoped method: GlideScopedEvaluator - GlideScopedEvaluator().

GlideScopedEvaluator - putVariable(String name, Object value)

Puts a variable into the GlideScopedEvaluator object. These variables are available to the script that this GlideScopedEvaluator object runs.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the variable.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>The value of the variable.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
//setting up a record that contains the script to be executed.
var now_GR = new GlideRecord('u_global_table');
now_GR.u_short_description = 'Calculate Addition';
now_GR.u_test_script = "result = x + y";
now_GR.insert();

var evaluator = new GlideScopedEvaluator();
evaluator.putVariable('x', 100);
evaluator.putVariable('y', 200);
evaluator.putVariable('result', null);

Output: 300
```
Scoped equivalent

To use the `putVariable()` method in a scoped application, use the corresponding scoped method: `GlideScopedEvaluator - putVariable(String name, Object value).

**GlideScopedEvaluator - Scoped**

The Glide ScopedEvaluator API allows you to evaluate scripts in a GlideRecord field from both scoped and global server scripts.

The GlideScopedEvaluator API evaluates records with script fields defined. The scope of the script is defined by the scope of the record.

**GlideScopedEvaluator - evaluateScript(GlideRecord grObj, String scriptField, Object variables)**

Evaluates a script from a GlideRecord field.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grObj</td>
<td>GlideRecord</td>
<td>The GlideRecord containing a script expression.</td>
</tr>
<tr>
<td>scriptField</td>
<td>String</td>
<td>(Optional) The name of the field containing the script expression.</td>
</tr>
<tr>
<td>variables</td>
<td>Object</td>
<td>(Optional) A map of variables with name-value pairs. These variables are available to the script during execution of this method.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The result of the script execution.</td>
</tr>
</tbody>
</table>

```java
// For this example, we created a table: "x_app_table" with two columns:
"short_description", "test_script"
// "test_script" will store the script to be evaluated by GlideScopedEvaluator.
var now_GR = new GlideRecord('x_app_table');
now_GR.short_description = 'Testing GlideScopedEvaluator';
now_GR.test_script = "gs.getUser().getName() + ' says ' + greeting; ";
now_GR.insert();

// setup variables to be used by the script
```
var vars = {'greeting' : 'hello'};

//Evaluate the script from the field
var evaluator = new GlideScopedEvaluator();
gs.info(evaluator.evaluateScript(now_GR, 'test_script', vars));

// Now retrieve the result
evaluator.evaluateScript(gr, 'u_test_script', null);
gs.info(evaluator.getVariable('result'));

Output: admin says hello

**GlideScopedEvaluator - getVariable(String name)**

Returns a variable from a GlideScopedEvaluator object.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>name</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Object</td>
</tr>
</tbody>
</table>

//setting up a record that contains the script to be executed.
var now_GR = new GlideRecord('u_global_table');
now_GR.u_short_description = 'Calculate Addition';
now_GR.u_test_script = "result = x + y";
now_GR.insert();

var evaluator = new GlideScopedEvaluator();
evaluator.putVariable('x', 100);
evaluator.putVariable('y', 200);
evaluator.putVariable('result', null);

**GlideScopedEvaluator - GlideScopedEvaluator()**

Instantiates a GlideScopedEvaluator object.
### GlideScopedEvaluator - putVariable(String name, Object value)

Puts a variable into the GlideScopedEvaluator object. These variables are available to the script that this GlideScopedEvaluator object runs.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the variable.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>The value of the variable.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
//setting up a record that contains the script to be executed.
var now_GR = new GlideRecord('u_global_table');
now_GR.u_short_description = 'Calculate Addition';
now_GR.u_test_script = "result = x + y";
now_GR.insert();

var evaluator = new GlideScopedEvaluator();
evaluator.putVariable('x', 100);
evaluator.putVariable('y', 200);
evaluator.putVariable('result', null);
```

Output: 300

### GlideExcelParser - Scoped, Global

Parse .xlsx formatted Excel files and access file data in script.

The GlideExcelParser methods can be used in global and scoped scripts. Use the `sn_impex` namespace identifier to create a GlideExcelParser object.
GlideExcelParser - close()
Close the connection to the input stream and release the document.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideExcelParser - getColumnHeaders()
Returns a list of column headers from the parsed document.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of strings of column headers from the parsed document.</td>
</tr>
</tbody>
</table>

GlideExcelParser - getErrorMessage()
Returns the error message when the parse() method fails.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The error message.</td>
</tr>
</tbody>
</table>

GlideExcelParser - `getRow()`

Get the current row values and headers.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The row headers are property names and the row values are property values.</td>
</tr>
</tbody>
</table>

GlideExcelParser - `getSheetNames()`

Gets a list of all worksheet names in an Excel workbook.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Array of strings as worksheet names ordered as positioned from left to right in the workbook. Results include any worksheets marked as hidden.</td>
</tr>
</tbody>
</table>

The following example shows how to parse an Excel file attachment multiple times to retrieve column headers and print values of each row for each worksheet. Results display column headers and values of three separate sheets in the Excel attachment.
var parser = new sn_impex.GlideExcelParser();

var attachment = new GlideSysAttachment();

// Use the attachment sys_id of an Excel file
var attachmentStream = attachment.getContentStream("<attachment_sys_id>");

// Set the source to be parsed
parser.setSource(attachmentStream);

// Get the worksheet names to be parsed in the Excel document
var list_sheet_name = parser.getSheetNames();

gs.info(" Sheet Names " + list_sheet_name.join(" ", ");

// Iterate over each worksheet in the Excel workbook
for (var i = 0; i < list_sheet_name.length; i++) {

    gs.info("*********************************************************************************
    *****
    Sheet name: " + list_sheet_name[i]);

    // Set the worksheet name to be parsed
    parser.setSheetName(list_sheet_name[i]);

    // Parse each worksheet set using setSheetName()
    if (parser.parse()) {
        //retrieve the column headers
        var headers = parser.getColumnHeaders();
        var header1 = headers[0];
        var header2 = headers[1];
        var header3 = headers[2];

        //print headers
        gs.info(header1 + "\t" || header2 + "\t" || header3);

        // Iterate over each row in the worksheet
        while (parser.next()) {
            var row = parser.getRow();
            //print row value for both columns
            gs.info(row[header1] + "\t" || row[header2] + "\t" || row[header3])
        }
    }
}

else
gs.info(parser.getErrorMessage());

Output:

GlideExcelParser - getTableInfo()

Gets table column types and max character length from a spreadsheet or CSV attachment.

⚠️ Note: This method is restricted to scoped applications.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Returns attachment data as a map in which the key is column name. Values contain column type and maximum length of a character string in the column. Access return values using the <code>getType()</code> and <code>getLength()</code> methods.</td>
</tr>
</tbody>
</table>

This example shows how to data from a 7-column spreadsheet attachment including row data such as 1, Meghan, 1/1/85, 1:00 AM, 10.00%, 224-432-8582, ½.

```javascript
var attachmentSysId = "<sys_id>";
var headerRowNumber = 6;

var attachmentStream = new GlideSysAttachment().getContentStream(attachmentSysId);
var parser = new sn_impex.GlideExcelParser();
parser.setHeaderRowNumber(headerRowNumber);
if (!parser.parse(attachmentStream)) {
    throw "Attachment could not be parsed as an Excel Spreadsheet " + attachmentSysId;
}
var tableInfo = parser.getTableInfo();
for (var name in tableInfo) {
    gs.info('Column Name : ' + name + ', Type : ' + tableInfo[name].getType() + ', Max Length : ' + tableInfo[name].getLength());
}

Output:

ProgressWorker: Attempted to get non-existent sys_progress_worker record, inserted 81b0ca5ddbb59730090c9ff9dbf9619c4
sn_appcreator: Column Name : My Number Col, Type : integer, Max Length : 1

sn_appcreator: Column Name : My Percent Col, Type : decimal, Max Length : 6
sn_appcreator: Column Name : My Phone Col, Type : string, Max Length : 12
sn_appcreator: Column Name : My Fraction Col, Type : decimal, Max Length : 3
```
GlideExcelParser - GlideExcelParser()

Creates an instance of GlideExcelParser.

The API name space identifier "sn_impex" must be used when creating a GlideExcelParser object.

```
var parser = new sn_impex.GlideExcelParser();
var attachment = new GlideSysAttachment();
// use attachment sys id of an excel file
var attachmentStream = attachment.getContentStream(<attachment sys id>);

parser.parse(attachmentStream);

//retrieve the column headers
var headers = parser.getColumnHeaders();
var header1 = headers[0];
var header2 = headers[1];

//print headers
gs.info(header1 + " " + header2);

while(parser.next()) {
    var row = parser.getRow();
    //print row value for both columns
    gs.info(row[header1] + ' ' + row[header2])
}
```

GlideExcelParser - next()

Moves to the next row.

```
```

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### GlideExcelParser - parse(InputStream inputStream)

Parses an XLSX-formatted Excel document.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputStream</td>
<td>GlideScriptableInputStream</td>
<td>Excel document provided as an input stream.</td>
</tr>
</tbody>
</table>

**Note:** Do not set this value if using the setSource() method to parse the same source multiple times.

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates if the parse was successful. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Document was successful parsed.</td>
</tr>
<tr>
<td></td>
<td>• false: Document was not successfully parsed.</td>
</tr>
</tbody>
</table>

Example from a scripted REST API script where the Excel file is sent using an input stream in the request payload.

```java
var parser = new sn_impex.GlideExcelParser();
parser.parse(request.body.dataStream);
```

The following example shows how to parse an Excel file attachment multiple times to retrieve column headers and print values of each row for each worksheet. Results display column headers and values of three separate sheets in the Excel attachment.

```java
var parser = new sn_impex.GlideExcelParser();
```
var attachment = new GlideSysAttachment();

// Use the attachment sys_id of an Excel file
var attachmentStream = attachment.getContentStream("<attachment_sys_id>");

// Set the source to be parsed
parser.setSource(attachmentStream);

// Get the worksheet names to be parsed in the Excel document
var list_sheet_name = parser.getSheetNames();

gs.info(" Sheet Names "+ list_sheet_name.join(" ", ");

// Iterate over each worksheet in the Excel workbook
for (var i = 0; i < list_sheet_name.length; i++) {
    gs.info("*********************************************************************************
*****");
    gs.info("Sheet name: "+ list_sheet_name[i]);

    // Set the worksheet name to be parsed
    parser.setSheetName(list_sheet_name[i]);

    // Parse each worksheet set using setSheetName()
    if (parser.parse()) {
        //retrieve the column headers
        var headers = parser.getColumnHeaders();
        var header1 = headers[0];
        var header2 = headers[1];
        var header3 = headers[2];

        //print headers
        gs.info(header1 + "|" + header2 + "|" + header3);

        // Iterate over each row in the worksheet
        while (parser.next()) {
            var row = parser.getRow();
            //print row value for both columns
            gs.info(row[header1] + ' ' + row[header2] + ' ' + row[header3])
        }
    } else
        gs.info(parser.getErrorMessage());
}

GlideExcelParser - setHeaderRowNumber(Number headerRowNumber)
Set the number of the header row to be retrieved.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>headerRowNumber</td>
<td>Number</td>
<td>The header row to be retrieved.</td>
</tr>
</tbody>
</table>
### GlideExcelParser - setNullToEmpty(Boolean empty)

Return an empty value instead of null when an Excel cell is not present.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>empty</td>
<td>Boolean</td>
<td>When true, cells that are not present return an empty value. When false, cells that are not present return null.</td>
</tr>
</tbody>
</table>

### GlideExcelParser - setSheetName(String sheetName)

Set the name of the sheet to be retrieved.

If both `setSheetNumber()` and `setSheetName()` are set, `setSheetName()` is used.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sheetName</td>
<td>String</td>
<td>The name of the sheet to be retrieved.</td>
</tr>
</tbody>
</table>

### GlideExcelParser - setSheetNumber(Number sheetNumber)

Set the number of the Excel sheet to be retrieved.
If both `setSheetNumber()` and `setSheetName()` are set, `setSheetNumber()` is ignored.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sheetNumber</td>
<td>Number</td>
<td>The Excel sheet number to retrieve.</td>
</tr>
</tbody>
</table>

### GlideExcelParser - `setSource(InputStream inputStream)`

Defines an input source for parsing multiple times or parsing each worksheet in an Excel file.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputStream</td>
<td>GlideScriptableInputStream</td>
<td>Excel document provided as an input stream.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to parse an Excel file attachment multiple times to retrieve column headers and print values of each row for each worksheet. Results display column headers and values of three separate sheets in the Excel attachment.

```java
var parser = new sn_impex.GlideExcelParser();

var attachment = new GlideSysAttachment();

// Use the attachment sys_id of an Excel file
var attachmentStream = attachment.getContentStream("<attachment_sys_id>");

// Set the source to be parsed
parser.setSource(attachmentStream);
```
// Get the worksheet names to be parsed in the Excel document
var list_sheet_name = parser.getSheetNames();

gs.info(" Sheet Names " + list_sheet_name.join(" ", ");

// Iterate over each worksheet in the Excel workbook
for (var i = 0; i < list_sheet_name.length; i++) {
    gs.info("*********************************************************************************
*****
Sheet name:    " + list_sheet_name[i]);

    // Set the worksheet name to be parsed
    parser.setSheetName(list_sheet_name[i]);

    // Parse each worksheet set using setSheetName()
    if (parser.parse()) {
        //retrieve the column headers
        var headers = parser.getColumnHeaders();
        var header1 = headers[0];
        var header2 = headers[1];
        var header3 = headers[2];

        //print headers
        gs.info(header1 + "\t\t\t" + header2 + "\t\t\t" + header3);

        // Iterate over each row in the worksheet
        while (parser.next()) {
            var row = parser.getRow();
            //print row value for both columns
            gs.info(row[header1] + '\t' + row[header2] + '\t' + row[header3])
        }
    } else
    gs.info(parser.getErrorMessage());
}

Output:

*** Script:  Sheet Names Incident Table, sys_user Table, knowledge Table
*** Script:

Sheet name:    Incident Table
 *** Script: Number ||Opened ||Short description
GlideFilter - Scoped, Global

Enables filtering queries to determine if one or more records meet a specified set of requirements.

Methods for this API are accessible using the GlideFilter global object.

Case sensitivity

GlideFilter is case-sensitive by default. Use the setCaseSensitive() method to enable or disable case sensitivity. GlideRecord queries are case-insensitive.

The following example shows how a GlideRecord query is case-insensitive and results in the same user record with upper or lower case.

```javascript
var gr = new GlideRecord('sys_user');
gr.addQuery('first_name', 'Abel');
gr.query();
while (gr.next())
  gs.info("Upper case query: " + gr.getDisplayValue());

var gr = new GlideRecord('sys_user');
gr.addQuery('first_name', 'abel');
```
GlideRecord `query()` output shows the same results display regardless of case.

<table>
<thead>
<tr>
<th>Upper case query: Abel Tuter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lower case query: Abel Tuter</td>
</tr>
</tbody>
</table>

The following example shows how GlideFilter only retrieves the matched value of the record for the upper case condition. The lower case condition does not provide a match.

```javascript
// Matches the 'Abel Tuter' user record
var gr = new GlideRecord('sys_user');
gr.query();
var condition = 'first_name=Abel';
var glideFilter = new GlideFilter(condition, 'filterCondition');
while (gr.next()) {
    if (glideFilter.match(gr, true))
        gs.info("Upper case condition: " + gr.getDisplayValue());
}

// The following code does not match 'Abel Tuter' user record
var gr = new GlideRecord('sys_user');
gr.query();
var condition = 'first_name=abel';
var glideFilter = new GlideFilter(condition, 'filterCondition');
while (gr.next()) {
    if (glideFilter.match(gr, true))
        gs.info("Lower case condition: " + gr.getDisplayValue());
}
```

The output reveals that the filter only returns upper case results with default case-sensitivity:

| Upper case condition: Abel Tuter |

The following example shows how to disable GlideFilter case-sensitivity with the `setCaseSensitive()` method. The filter matches the condition even though the case does not match the field value.

```javascript
// Matches the 'Abel Tuter' user record
var gr = new GlideRecord('sys_user');
gr.query();
var condition = 'first_name=Abel';
var glideFilter = new GlideFilter(condition, 'filterCondition');
```
while (gr.next()) {
    if (glideFilter.match(gr, true))
        gs.info("Upper case condition: " + gr.getDisplayValue());
}

// The following code disables case sensitivity and matches the same record
var gr = new GlideRecord('sys_user');
gr.query();

var condition = 'first_name=abel';
var glideFilter = new GlideFilter(condition, 'filterCondition');
glideFilter.setCaseSensitive(false);

while (gr.next()) {
    if (glideFilter.match(gr, true))
        gs.info("Lower case condition: " + gr.getDisplayValue());
}

The output reveals GlideFilter case-insensitive results:

Upper case condition: Abel Tuter
Lower case condition: Abel Tuter

Filter null values
To exclude null values from GlideFilter query results, add ISNOTEMPTY to the query condition. The following example shows how using the same encoded query with GlideRecord and GlideFilter produces different results.

var insertRecordsGr = new GlideRecord('u_test_table');
insertRecordsGr.deleteMultiple();
var dates = ['', '2021-01-29', '2021-01-30', '2021-01-31'];
dates.forEach(function(val) {
    insertRecordsGr.initialize();
    insertRecordsGr.u_date_field = val;
    insertRecordsGr.insert();
});

var now_GR = new GlideRecord('u_test_table');
now_GR.addEncodedQuery('u_date_field<javascript:gs.beginningOfToday()');
now_GR.query();

// Encoded query includes null values with GlideFilter, which might cause unexpected results
var condition = 'u_date_field<javascript:gs.beginningOfToday()';
var grWithGlideFilter = new GlideRecord('u_test_table');
grWithGlideFilter.query();
var filter = new GlideFilter(condition, 'filterCondition');

var countWithGlideFilter = 0;
while (grWithGlideFilter.next()) {
    if (GlideFilter.checkRecord(grWithGlideFilter, condition))
        countWithGlideFilter++;
}

gs.info('Record RowCount: ' + now_GR.getRowCount() + ' - Filter Count: ' +
countWithGlideFilter);

The output shows that GlideRecord returns three records, skipping empty date
values. The GlideFilter query counts the empty date value and returns a count
of four records.

Record RowCount: 3 - Filter Count: 4

To exclude null values from the GlideFilter results, add an AND condition
ISNOTEMPTY to the queried field.

// Encoded query includes null values with GlideFilter
var condition = 'u_date_field<=javascript:gs.beginningOfToday()^u_date_fieldISNOTEMPTY';

Output shows that the GlideFilter encoded query skips the null date value and
counts three results.

Record RowCount: 3 - Filter Count: 3

GlideFilter – GlideFilter(String filter, String title)
Instantiates a GlideFilter object.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filter</td>
<td>String</td>
<td>Encoded query string in standard Glide format. See Encoded query strings. Results are case-sensitive, unless disabled using the setCaseSensitive() method. To exclude null values from GlideFilter query results, add ISNOTEMPTY to the query condition.</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>Descriptive title for the filter.</td>
</tr>
</tbody>
</table>
The following example shows how to filter the number of users named Rebekah.

```javascript
var now_GR = new GlideRecord('sys_user');
now_GR.query();
var condition = 'first_name=rebekah';
var filter = new GlideFilter(condition, 'filterCondition');
filter.setCaseSensitive(false);

var countResults = 0;
while (now_GR.next()) {
    if (filter.match(now_GR, true))
        countResults++;
}

gs.info('Number of users named Rebekah: ' + countResults);
```

Output:

```
Number of users named Rebekah: 2
```

**GlideFilter - checkRecord(GlideRecord now_GR, String filter, Boolean match)**

Compares a specified filter to the contents of a specified GlideRecord.

If the specified filter contains one condition, the method returns true if the record meets the condition.

Filters support multiple conditions, for example "active=true^number=abc^category=request". You can use the `match` parameter to define whether all conditions must be met to determine a match or just a single condition.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>GlideRecord to evaluate.</td>
</tr>
<tr>
<td>filter</td>
<td>String</td>
<td>Encoded query string in standard Glide format. See Encoded query strings.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>To exclude null values from GlideFilter query results, add ISNOTEMPTY to the query condition.</td>
</tr>
</tbody>
</table>

**Note:** The `filter` values are case-sensitive. In addition, you cannot use `setCaseSensitive(false)` to change the case-sensitive value.
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| match | Boolean    | Optional. Flag that indicates whether all conditions must be met if the filter parameter contains multiple conditions.  
Valid values:  
• true: All conditions must be met for the method to return true.  
• false: Only one of the conditions must be met for the method to return true.  
Default: true |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Results of the filter comparison.  
• true: Filter conditions were met.  
• false: Filter conditions were not met. |

The following example shows how to display true for each record in the Incident table that meets the filter condition. False otherwise.

```javascript
var rec = new GlideRecord('incident');
rec.query();

var bool = true;

while(rec.next())
{
    bool = GlideFilter.checkRecord(rec, "active=true");
    gs.info("number "+ rec.number + " is " + bool);
}
```

Output:

```
number INC0000060 is false  
number INC0009002 is false  
number INC0000009 is false  
...  
```
number INC0000015 is true
number INC0000016 is true
number INC0000017 is true
...

**GlideFilter - match(GlideRecord now_GR, String filter, Boolean match)**

Evaluates a filter against a specified GlideRecord.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>GlideRecord to evaluate.</td>
</tr>
</tbody>
</table>
| match   | Boolean     | Flag that indicates whether all filter conditions must match.
|         |             | Valid values:
|         |             | • true: All filter conditions must match.
|         |             | • false: Filter condition match is not required.
|         |             | Default: false                                  |

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Results of the match check.</td>
</tr>
<tr>
<td></td>
<td>• true: Filter conditions were met.</td>
</tr>
<tr>
<td></td>
<td>• false: Filter conditions were not met.</td>
</tr>
</tbody>
</table>

The following example shows how to ensure the filter conditions match against the GlideRecord provided.

```javascript
var now_GR = new GlideRecord('sys_user');
now_GR.query();
var condition = 'first_name=rebekah';
var filter = new GlideFilter(condition, 'filterCondition');
filter.setCaseSensitive(false);

var countResults = 0;
while (now_GR.next()) {
    if (filter.match(now_GR, true))
```
countResults++;
}

gs.info('Number of users named Rebekah: ' + countResults);

Output:
Number of users named Rebekah: 2

GlideFilter - setCaseSensitive(Boolean caseSensitive)
Enables or disables case-sensitive filter results.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| caseSensitiveBoolean | Boolean          | Flag that indicates whether the filter is case-sensitive. Valid values: 
|                    |                  | • true: The filter is case-sensitive. 
|                    |                  | • false: The filter is case-insensitive.          |
|                    |                  | Default: true                                    |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to disable case-sensitive results.

```javascript
var now_GR = new GlideRecord('sys_user');
own_GR.query();

var condition = 'first_name=rebekah';
var filter = new GlideFilter(condition, 'filterCondition');

// Disable case-sensitive filtering
filter.setCaseSensitive(false);

while (now_GR.next()) {
    if (filter.match(now_GR, true))
```
Output shows that the filter retrieves upper case results with a lower case condition.

GlideFlow - Client

Use the GlideFlow JavaScript API for client-side interactions with actions, flows, and subflows.

Use the GlideFlow API anywhere in the platform that accepts client scripts. The action, flow, or subflow must be set as client callable, and have a valid ACL using the Manage Security feature in Flow designer.

Some of the methods within GlideFlow return promise objects. A promise represents the eventual result of an asynchronous operation. For more information on promises, see Promise - Javascript MDN or AngularJS documentation.

Using this API, you can:

• Start actions, flows, or subflows via a script.
• Get an existing execution.
• Get the status and any available outputs.
• Wait for the completion of an action, flow, or subflow.

There is no constructor for the GlideFlow class. Access GlideFlow methods using the GlideFlow global object.

GlideFlow - getExecution(String executionId)
Get an existing execution instance by ID.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>executionId</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>A promise of an execution object.</td>
</tr>
</tbody>
</table>

In this example, the code gets an execution, then waits for it to be completed before logging the executions completion status and outputs using console.log.

```javascript
// Get an existing action and await completion
(function() {
  GlideFlow.getExecution('79cd437e0b202300a150a95e93673ae3')
    .then(function(execution) {
      return execution.awaitCompletion();
    }, errorResolver)
    .then(function(completion) {
      var status = completion.status;
      console.log(status);
      // Available Outputs:
      var outputs = completion.outputs;
      console.log(outputs);
    }, errorResolver());

  function errorResolver(error) {
    // Handle errors in error resolver
    console.error(error);
  }
})();
```

**GlideFlow - startAction(String scopedName, Map inputs)**

Start an action.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scopedName</td>
<td>String</td>
<td>The scoped name of the flow to be executed.</td>
</tr>
<tr>
<td>inputs</td>
<td>Object</td>
<td>An object containing inputs defined for the action.</td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td>Object</td>
<td>An object containing details on the action execution.</td>
<td></td>
</tr>
</tbody>
</table>

In this example, the code starts the global action_name action using arguments in the inputs input object variable. Upon completion, the example uses console.log or console.error to report on the success or failure of the flow.

```javascript
// Start an action and await completion.
(function() {
    var inputs = {};

    inputs['input1'] = 'string input'; // String

    GlideFlow.startAction('global.action_name', inputs)
        .then(function(execution) {
            return execution.awaitCompletion();
        }, errorResolver)
        .then(function(completion) {
            var status = completion.status;
            console.log(status);

            // Available Outputs:
            var outputs = completion.outputs;
            console.log(outputs);
        }, errorResolver());

    function errorResolver(error) {
        // Handle errors in error resolver
        console.error(error);
    }
})();
```

**GlideFlow - startFlow(String scopedName.flowName, Map inputs)**

Start a flow.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scopedName</td>
<td>String</td>
<td>The scoped name of the flow to be executed.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputs</td>
<td>Object</td>
<td>An object containing inputs defined for the flow.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object containing details on the flow execution.</td>
</tr>
</tbody>
</table>

This example flow is normally triggered when a record on the incident table is updated. Because you are activating the flow from Client script, you must provide this information. The code creates an inputs variable that contains the current record and the table for the record.

```javascript
// Start a Flow
(function() {
    var inputs = {};
    inputs['current'] = { // GlideRecord
        table : 'incident',
        sys_id : '79cd437e0b202300a150a95e93673ae3'
    };
    inputs['table_name'] = 'incident';
    GlideFlow.startFlow('global.flow_name', inputs)
    .then(
        function(execution) {
            console.log('Started flow_name with execution id :' + execution.getExecutionId());
        },
        function(error) {
            console.log('Unable to start flow: ' + error);
        }
    );
})();
```

**GlideFlow - startSubflow(String scopedName.subflowName, Map inputs)**

Start a subflow.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scopedName</td>
<td>String</td>
<td>The scoped name of the flow to be executed.</td>
</tr>
<tr>
<td>inputs</td>
<td>Object</td>
<td>An object containing inputs used for the subflow.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object containing details on the subflow execution.</td>
</tr>
</tbody>
</table>

In this example, the code starts the global subflow_name subflow using arguments in the inputs array variable. Upon completion, the example uses console.log or console.error to report on the success or failure of the flow.

```javascript
// Start an action and await completion.
(function() {
    var inputs = {};
    inputs['input1'] = 'string input'; // String

    GlideFlow.startSubflow('global.subflow_name', inputs)
        .then(function(execution) {
            return execution.awaitCompletion();
        }, errorResolver)
        .then(function(completion) {
            var status = completion.status;
            console.log(status);

            // Available Outputs:
            var outputs = completion.outputs;
            console.log(outputs);
            }, errorResolver());

    function errorResolver(error) {
        // Handle errors in error resolver
        console.error(error);
    }
})();
```
**GlideFlow - execution.awaitCompletion()**

Returns a completion object for the execution.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object that contains completion details for a flow or action execution.</td>
</tr>
</tbody>
</table>

In this example, an action is executed using `startAction()`, which returns an execution object. The code then uses `awaitCompletion()` on this execution object, which returns a completion object. The code uses this completion object to log the status and outputs within the execution.

```javascript
(function() {
    var inputs = {};

    inputs['input1'] = 'string input'; // String

    GlideFlow.startAction('global.action_name', inputs)
        .then(function(execution) {
            return execution.awaitCompletion();
        }, errorResolver)
        .then(function(completion) {
            var status = completion.status;
            console.log(status);

            // Available Outputs:
            var outputs = completion.outputs;
            console.log(outputs);
        }, errorResolver());

    function errorResolver(error) {
        // Handle errors in error resolver
        console.error(error);
    }

})(function() {
    var inputs = {};

    inputs['input1'] = 'string input'; // String

    GlideFlow.startAction('global.action_name', inputs)
        .then(function(execution) {
            return execution.awaitCompletion();
        }, errorResolver)
        .then(function(completion) {
            var status = completion.status;
            console.log(status);

            // Available Outputs:
            var outputs = completion.outputs;
            console.log(outputs);
        }, errorResolver());

    function errorResolver(error) {
        // Handle errors in error resolver
        console.error(error);
    }
```

**GlideFlow - execution.getExecutionStatus()**

Returns a string containing the execution status of the current execution.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A string containing the execution status.</td>
</tr>
</tbody>
</table>

In this example, the code obtains an execution object using the getExecution method. The getExecution method requires an ID, which is returned by the method used to start the execution. The code then uses getExecutionStatus() to determine whether the execution has been completed before continuing.

```javascript
(function() {
  GlideFlow.getExecution('mamIN4Q35vmEFc744EwJV5GHRsz8fMjG')
  .then(function(execution) {
    execution.getExecutionStatus().then(
      function(status) {
        if (status === 'COMPLETE')
          execution.getOutputs().then(
            function(outputs) {
              console.log(outputs);
            },
            errorResolver
          ),
        errorResolver
      },
      errorResolver
    );
  },
  errorResolver
});

function errorResolver(error) {
  // Handle errors in error resolver
}
```
GlideFlow - execution.getOutputs()

Returns an outputs object for the execution.

Use this method to access output generated by the execution of an action, flow, or subflow.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object containing outputs for an action, flow, or subflow.</td>
</tr>
</tbody>
</table>

In this example, the code obtains an execution object using the getExecution method. After the execution is complete, the code uses getOutputs() to return an outputs object, which it then logs using the console.log method.

```javascript
console.error(error);
}
})

// Get an existing action, getStatus, and getOutputs if complete
(function() {
    GlideFlow.getExecution('mamIN4Q35vmEFv744EwJv5GHRsz8fmJG')
    .then(function(execution) {
        execution.getExecutionStatus().then(
            function(status) {
                if (status === 'COMPLETE')
                    execution.getOutputs().then(
                        function(outputs) {
                            console.log(outputs);
                        },
                        errorResolver
                    ),
                    errorResolver
                });
            },
            errorResolver
        ),
        errorResolver
    });
```
function errorResolver(error) {
    // Handle errors in error resolver
    console.error(error);
}
}}();

GlideForm - Client

The GlideForm API provides methods to customize forms.

GlideForm.js is the JavaScript class containing the methods. The global object g_form is used to access GlideForm methods. GlideForm methods are only used on the client. These methods are used to make custom changes to the form view of records. All validation of examples was done using client scripts.

Some of these methods can also be used in other client scripts (such as Catalog Client Scripts or Wizard Client Scripts), but must first be tested to determine whether they will work as expected.

⚠️ **Note:** The methods getControl(), getHelpTextControl(), getElement(), and getFormElement() are deprecated for mobile devices. For information on using GlideForm for mobile, see Mobile Client GlideForm (g_form) Scripting and Migration.

There is no constructor for the GlideForm class. Access GlideForm methods using the g_form global object.

GlideForm - addDecoration(String fieldName, String icon, String title)

Adds an icon on a field’s label.

Adding the same item twice is prevented; however, you can add the same icon with a different title.

⚠️ **Note:** This method is not supported by Service Catalog.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
<tr>
<td>icon</td>
<td>String</td>
<td>The font icon to show next to the field. Supported icons - icon-user, icon-user-group, icon-lightbulb, icon-home, icon-mobile, icon-comment, icon-mail, icon-locked, icon-</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

| title        | String | The text title for the icon.                                                 |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
const g_form = new GlideForm();
g_form.addDecoration('caller_id', 'icon-star', 'preferred member');
```

GlideForm - addDecoration(String fieldName, String icon, String title, String color)

Adds an icon on a field's label.

Adding the same item twice is prevented; however, you can add the same icon with a different title.

⚠️ Note: This method is not supported by Service Catalog.
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>color</td>
<td>String</td>
<td>A CSS color.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
g_form.addDecoration('caller_id', 'icon-star', 'Mark as Favorite', 'color-green');
```

GlideForm - addErrorMessage(String message)

Displays the specified error message at the top of the form.

This message appears for approximately four seconds and then disappears. This timeout is not configurable at this time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Message to display.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
g_form.addErrorMessage('This is an error');
```
GlideForm - addFormMessage(String message, String type)
Displays a floating form message at the top of the form detail section. The message does not cover UI actions.

See also:
• clearAllFormMessages()
• clearFormMessages()

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Message to display.</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>The type of message. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• error</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• info</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• warning</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to add form messages of each type.

```java
    g_form.addFormMessage('info message','info');
    g_form.addFormMessage('warning message','warning');
    g_form.addFormMessage('error message','error');
    g_form.addFormMessage('info2 message','info');
    g_form.addFormMessage('warning2 message','warning');
    g_form.addFormMessage('error2 message','error');
```

GlideForm - addInfoMessage(String message)

Adds the specified informational message to the top of the form.

This message appears for approximately four seconds and then disappears. This timeout is not configurable at this time.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Message to display.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
g_form.addInfoMessage('The top five fields in this form are mandatory');
```

**GlideForm - addOption(String fieldName, String choiceValue, String choiceLabel)**

Adds a choice to the end of a choice list field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The name of the field.</td>
</tr>
<tr>
<td>choiceValue</td>
<td>String</td>
<td>The value to be stored in the database.</td>
</tr>
<tr>
<td>choiceLabel</td>
<td>String</td>
<td>The value displayed.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
g_form.addOption('priority', '6', '6 - Really Low');
```

**GlideForm - addOption(String fieldName, String choiceValue, String choiceLabel, Number choiceIndex)**

Adds a choice to the choice list field at the position specified.

```javascript
g_form.addOption('priority', '6', '6 - Really Low');
```
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
<tr>
<td>choiceValue</td>
<td>String</td>
<td>The value stored in the database.</td>
</tr>
<tr>
<td>choiceLabel</td>
<td>String</td>
<td>The value displayed.</td>
</tr>
<tr>
<td>choiceIndex</td>
<td>Number</td>
<td>Order of the choice in the list. The index is into a zero based array.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
GlideForm.addOption('priority', '2.5', '2.5 - Moderately High', 3);
```

**GlideForm - clearMessages()**

Removes all informational and error messages from the top of the form.

Removes informational and error messages added with `GlideForm.addInfoMessage()` and `GlideForm.addErrorMessage()`.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
GlideForm.clearMessages();
```

**GlideForm - clearAllFormMessages()**

Removes all form messages of any type.
See also:

- `addFormMessage()`
- `clearFormMessages()`

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to clear all messages from the form.

```javascript
g_form.clearAllFormMessages();
```

**GlideForm - clearFormMessages(String type)**

Removes all form messages of a given type.

See also:

- `addFormMessage()`
- `clearAllFormMessages()`

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| type | String| The type of message. Valid values:  
  - error  
  - info   
  - warning |
The following example shows how to clear all error messages from the form:

```javascript
g_form.clearFormMessages('error');
```

**GlideForm - clearOptions(String fieldName)**

Removes all options from the choice list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideForm - clearValue(String fieldName)**

Removes any value(s) from the field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideForm - disableAttachments()**

Prevents file attachments from being added.
This method is not available on the mobile platform. If this method is run on a mobile platform, no action occurs.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideForm - enableAttachments()**

Allows file attachments to be added. Shows the paper clip icon.

This method is not available on the mobile platform. If this method is run on a mobile platform, no action occurs.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideForm - flash(String fieldName, String color, Number count)**

Used to draw attention to a particular field. Flashes the specified color for a specified duration of time in the specified field.

This method is not supported by Service Catalog.

This method is not available on the mobile platform. If this method is run on a mobile platform, no action occurs.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Specifies the field to highlight in the following format: &quot;&lt;table-name&gt;.&lt;field-name&gt;&quot;.</td>
</tr>
<tr>
<td>color</td>
<td>String</td>
<td>RGB color or acceptable CSS color.</td>
</tr>
<tr>
<td>count</td>
<td>Number</td>
<td>Specifies how long the label will flash. Options include:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 2: Flashes for 1 second</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 0: Flashes for 2 seconds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• -2: Flashes for 3 seconds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• -4: Flashes for 4 seconds</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```
g_form.flash("incident.number", "#FFFACD", 0);
```

GlideForm - getActionName()

Returns the most recent action name, or, for a client script, the sys_id of the UI action clicked.

ℹ️ Note: Not available in Wizard client scripts.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The current action name.</td>
</tr>
</tbody>
</table>
function onSubmit() {
    var action = g_form.getActionName();
    alert('You pressed ' + action);
}

**GlideForm - getBooleanValue(String fieldName)**

Returns a Boolean value for the specified field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns false if the field value is false or undefined; otherwise returns true.</td>
</tr>
</tbody>
</table>

**GlideForm - getControl(String fieldName)**

Returns the HTML element for the specified field.

Compound fields may contain several HTML elements. This method is generally not necessary as there are built-in methods that use the fields on a form.

If the field is a reference field and the control is a choice list, `getControl()` may not return a control as expected. In this case, use `sys_select.<table name>..<field name>`. This method is not available in mobile scripts or Service Portal scripts.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTMLElement</td>
<td>The field's HTML element.</td>
</tr>
</tbody>
</table>

**GlideForm - getDecimalValue(String fieldName)**

Returns the decimal value of the specified field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The name of the field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The decimal value of the specified field.</td>
</tr>
</tbody>
</table>

```javascript
function onChange(control, oldValue, newValue, isLoading) {
    alert(g_form.getDecimalValue('percent_complete'));
}
```

**GlideForm - getElement(String id)**

Returns the HTML element specified by the parameter.

Compound fields may contain several HTML elements. This method is generally not necessary as there are built-in methods that use the fields on a form. This method is not available in mobile scripts or Service Portal scripts.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>The field id.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTMLElement</td>
<td>The field's HTML element.</td>
</tr>
</tbody>
</table>

**GlideForm - getFormElement()**

Returns the HTML element for the form.

This method is not available in mobile scripts or Service Portal scripts.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTMLFormElement</td>
<td>The HTML element for the form.</td>
</tr>
</tbody>
</table>

**GlideForm - getHelpTextControl(String fieldName)**

Returns the HTML element of the help text for the specified field.

This method is applicable to service catalog variables only.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTMLElement</td>
<td>Help text field's HTML element.</td>
</tr>
</tbody>
</table>
**GlideForm - getIntValue(String fieldName)**

Returns the integer value of the field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Integer value of the field.</td>
</tr>
</tbody>
</table>

**GlideForm - getLabelOf(String fieldName)**

Returns the plain text value of the field label.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The label text.</td>
</tr>
</tbody>
</table>

```javascript
if (g_user.hasRole('itil')) {
    var oldLabel = g_form.getLabelOf('comments');
    g_form.setLabelOf('comments', oldLabel + ' (Customer visible)');
}
```

**GlideForm - getOption(String fieldName, String choiceValue)**

Returns the option element for a selected box named `fieldName` where `choiceValue` matches the option value.

**Note:** This method does not work on read-only fields.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
<tr>
<td>choiceValue</td>
<td>String</td>
<td>Value of the option.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTMLElement</td>
<td>The HTMLElement for the option. Returns null if the field or option is not found.</td>
</tr>
</tbody>
</table>

The following example shows how to get the label for a choice list value.

```
// Get the label for a choice list value
// fieldName is 'category'

function onChange(control, oldValue, newValue, isLoading) {
  var choiceValue = g_form.getValue('category');
  var choiceLabel = g_form.getOption('category', choiceValue).text;
}
```

**GlideForm - getRelatedListNames()**

Returns an array of related lists from the current form in the order in which they appear on that form.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Array of related lists from the current form in the order in which they appear on that form.</td>
</tr>
</tbody>
</table>
for (var i = 0; i < listNames.length; i++) {
    this.showRelatedList(listNames[i]);
}

**GlideForm - getReference(String fieldName, Function callBack)**

Returns the GlideRecord for a specified field.

If a callback function is present, this routine runs asynchronously. The browser (and script) processing continues normally until the server returns the reference value, at which time, the callback function is invoked. If a callback function is not present, this routine runs synchronously and processing halts (causing the browser to appear to hang) while waiting on a server response.

⚠️ **Important:** It is strongly recommended that you use a callback function.

Callback function support for ServiceCatalogForm.getReference is available.

⚠️ **Note:** Using this method requires a call to the server which requires additional time and may introduce latency to your page. Use this method with caution. For additional information, see Client script design and processing.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
<tr>
<td>callBack</td>
<td>Function</td>
<td>Name of the call back function.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>GlideRecord object for the specified field.</td>
</tr>
<tr>
<td></td>
<td>If the specified reference cannot be found, it returns an initialized GlideRecord object where currentRow = -1 and rows.length = 0.</td>
</tr>
</tbody>
</table>

```javascript
function onChange(control, oldValue, newValue, isLoading) {
    g_form.getReference('caller_id', doAlert); // doAlert is our callback function
}

function doAlert(caller) { // reference is passed into callback as first arguments
    ...
}
```
if (caller.getValue('vip') == 'true') {
    alert('Caller is a VIP!');
}

GlideForm - getSectionNames()

Returns all section names, whether visible or not.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array of strings</td>
<td>The section names.</td>
</tr>
</tbody>
</table>

GlideForm - getSections()

Returns an array of the form's sections.

This method is not available on the mobile platform. If this method is run on a mobile platform, no action occurs.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array of HTML elements</td>
<td>The form's sections.</td>
</tr>
</tbody>
</table>

function onChange(control, oldValue, newValue, isLoading) {
    //this example was run on a form divided into sections (Change form)
    // and hid a section when the "state" field was changed
    var sections = g_form.getSections();
if (newValue == '2') {
    g_form.setSectionDisplay(sections[1], false);
} else {
    g_form.setSectionDisplay(sections[1], true);
}

**GlideForm - getTableName()**

Returns the name of the table to which this record belongs.

On the server side, the table for the current record can be retrieved with current.sys_class_name or current.getTableName().

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of the table.</td>
</tr>
</tbody>
</table>

function onLoad() {
    if (g_form.isNewRecord()) {
        var tableName = g_form.getTableName(); //Get the table name
    }
}

**GlideForm - getUniqueValue()**

Returns the sys_id of the record displayed in the form.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The record’s sys_id.</td>
</tr>
</tbody>
</table>

```
function onLoad() {
    var incSysid = g_form.getUniqueValue();
    alert(incSysid);
}
```

**GlideForm - getValue(String fieldName)**

Returns the value of the specified form field.

This method also supports getting values from a multi-row variable set (MRVS). To obtain data from fields within an MRVS, you must first use `JSON.parse(getValue('<mrvs_field_name>'))` to obtain the MRVS array, and then use indexing to access the fields within the row objects. For more details, see the code example below.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field whose value to return.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>String</td>
<td>Value of the specified field.</td>
</tr>
</tbody>
</table>

The following example shows how to get the short description from the current form.

```
function onChange(control, oldValue, newValue, isLoading) {
    alert(g_form.getValue('short_description'));
}
```

The following example shows how to get values from an MVRS. In this example, salaries are being managed through the Service Catalog. The client script searches all rows within the MRVS for the value entered in the **Job title** and then updates the matching entries within the MVRS with what is entered in the **Job title**.
Salary field. The MRVS is named "variable_set_1" and contains the following fields within each row object: Employee name [employee_name], Job title [employee_job_title], and Salary [employee_salary]. In addition, the Catalog Item contains: Job title [job_title] and Salary [salary].

```javascript
function onChange(control, oldValue, newValue, isLoading) {
  if (isLoading || newValue == '') {
    return;
  }

  // Get the MRVS
  var multiRowVariableSet = JSON.parse(g_form.getValue('variable_set_1'));

  for (var i = 0; i < multiRowVariableSet.length; i++) {
    // Check if the entered job title matches the title in the current MRVS row
    if (multiRowVariableSet[i].employee_job_title == g_form.getValue("job_title")) {
      // Update the value of a matching field with the new salary
      multiRowVariableSet[i].employee_salary = newValue;
    }
  }

  // Update the MRVS
  g_form.setValue('variable_set_1', JSON.stringify(multiRowVariableSet));
}
```

**GlideForm - hideAllFieldMsgs()**

Hides all field messages.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideForm - hideAllFieldMsgs(String type)**

Hides all field messages of the specified type.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>The type of message. Valid values: • error • info</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideForm - hideErrorBox(String fieldName)**

Hides the error message placed by `showErrorBox()`.

Whenever possible, use `hideFieldMsg()` rather than this method whenever possible.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The name of the field or control.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideForm - hideFieldMsg(String fieldName)**

Hides the last message placed by `showFieldMsg()`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>
Returns
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideForm - hideFieldMsg(String fieldName, Boolean clearAll)**

Hides the messages placed by `showFieldMsg()`.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
<tr>
<td>clearAll</td>
<td>Boolean</td>
<td>When true, all messages for the field are cleared. When false, only the last message is removed.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
    g_form.hideFieldMsg('impact', true);
```

**GlideForm - hideRelatedList(String listTableName)**

Hides the specified related list on the form.

This method is not available on the mobile platform. If this method is run on a mobile platform, no action occurs.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>listTableName</td>
<td>String</td>
<td>Name of the related list. Use the sys_id to hide a list through a relationship.</td>
</tr>
</tbody>
</table>
GlideForm - hideRelatedLists()

Hides all related lists on the form.

This method is not available on the mobile platform. If this method is run on a mobile platform, no action occurs.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

GlideForm - isLiveUpdating()

Returns true while a live update is being done on the record the form is showing.

This can be used in an `onChange()` client script to determine if a change to the record is because of a live update from another session. The client script can then decide what action to take, or not to take. This applies to systems using UI16 with live forms enabled.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if a live update is happening on the record displayed by the form.</td>
</tr>
</tbody>
</table>

**GlideForm - isMandatory(String fieldName)**

Returns true if the field is mandatory.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the field is required, false otherwise.</td>
</tr>
</tbody>
</table>

**GlideForm - isNewRecord()**

Returns true if the record has never been saved.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if the record has not been saved; otherwise false.</td>
</tr>
</tbody>
</table>

```javascript
function onLoad() {
    if (g_form.isNewRecord()){
        alert('New Record!');
    }
}
```
**GlideForm - isSectionVisible(String sectionName)**

Returns true if the section is visible.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true when the section is visible; otherwise, false is returned.</td>
</tr>
</tbody>
</table>

**GlideForm - onUserChangeValue(Function fn)**

Registers a custom event listener that detects when any field in the current form is modified by a user.

When a form field is modified, the event listener calls the function that is passed in when the listener is initially registered. This listener is only triggered when a user makes a change to a field on the form. Changes from client scripts, UI policies, or any other non-user interactions, do not trigger the listener.

⚠️ **Note:** This method does not work for journal fields.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fn</td>
<td>Function</td>
<td>Function to call when a user changes the value of a field within the current form. This is actually the function code, not just the function name. This function must accept the following three arguments:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• field name</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• original field value</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• updated field value</td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td>Function</td>
<td>Function to call to unregister the onUserChangeValue event listener.</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

```javascript
var handler = function(fieldname, originalValue, newValue) {
  console.log('The field (' + fieldname + ') has a new value of: ' + newValue); // function code
}

var unregister = g_form.onUserChangeValue(handler);

// To unregister the event listener
unregister();
```

**GlideForm - refreshSlushbucket(String fieldName)**

You can update a list collector variable.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the slush bucket.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
g_form.refreshSlushbucket('bucket');
```

**GlideForm - removeDecoration(String fieldname, String icon, String title)**

Removes the icon from the specified field that matches the icon and title.

ℹ️ **Note:** This method is not supported by Service Catalog.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Field name.</td>
</tr>
<tr>
<td>icon</td>
<td>String</td>
<td>Name of the icon to remove.</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>The icon's text title (name).</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
function onChange(control, oldValue, newValue, isLoading) {
  // if the caller_id field is not present, then we can't add an icon anywhere
  if (!g_form.hasField('caller_id'))
    return;
  if (!newValue)
    return;

g_form.getReference('caller_id', function(ref) {
  g_form.removeDecoration('caller_id', 'icon-star', 'VIP');
  if (ref.getValue('vip') == 'true')
    g_form.addDecoration('caller_id', 'icon-star', 'VIP');
});
}
```

**GlideForm - removeDecoration(String fieldName, String icon, String title, String color)**

Removes the icon from the specified field that matches the icon, title, and color.

ℹ️ **Note:** This method is not supported by Service Catalog.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Field name.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>icon</td>
<td>String</td>
<td>Name of the icon to remove.</td>
</tr>
<tr>
<td>title</td>
<td>String</td>
<td>The icon's text title (name).</td>
</tr>
<tr>
<td>color</td>
<td>String</td>
<td>A CSS color</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
g_form.removeDecoration('caller_id', 'icon-star', 'VIP', 'blue');
```

**GlideForm - removeOption(String fieldName, String choiceValue)**

Removes the specified option from the choice list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
<tr>
<td>choiceValue</td>
<td>String</td>
<td>The value stored in the database. This is not the label.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
g_form.removeOption('priority', '1');
```

**GlideForm - save()**

Saves the record without navigating away (update and stay).
GlideForm - `setDisabled(String fieldName, Boolean disable)`

Makes the specified field available or unavailable.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
<tr>
<td>disable</td>
<td>Boolean</td>
<td>When true disables the field. When false enables the field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideForm - `setDisplay(String fieldName, Boolean display)`

Displays or hides a field.

This method cannot hide a mandatory field with no value. If the field is hidden, the space is used to display other items. Whenever possible, use a UI policy instead of this method.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>display</td>
<td>Boolean</td>
<td>When true displays the field, when false hides the field.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
function onChange(control, oldValue, newValue, isLoading, isTemplate) {
    // If the page isn't loading
    if (!isLoading) {
        // If the new value isn't blank
        if (newValue != '') {
            g_form.setDisplay('priority', false);
        } else {
            g_form.setDisplay('priority', true);
        }
    }
    //glideform function
}
```

### GlideForm - setLabelOf(String fieldName, String label)

Sets the plain text value of the field label.

⚠️ **Note:** This method is not supported by Service Catalog.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
<tr>
<td>label</td>
<td>String</td>
<td>The field text label.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
if (g_user.hasRole('itil')) {
    var oldLabel = g_form.getLabelOf('comments');
    g_form.setLabelOf('comments', oldLabel + ' (Customer visible)');
}

GlideForm - setMandatory(String fieldName, Boolean mandatory)
Makes the specified field mandatory.
Whenever possible, use a UI policy rather than this method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
<tr>
<td>mandatory</td>
<td>Boolean</td>
<td>When true makes the field mandatory. When false makes the field optional.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideForm - setReadOnly(String fieldName, Boolean readOnly)
Makes the specified field read-only or editable.
Whenever possible, use a UI policy instead of this method.
To make a mandatory field read-only, you must first remove the mandatory requirement for that field by using the setMandatory() method.
Once you set a field to read-only, you cannot use the setValue() method to update the value of that field. If you need to set the value in this way, you must set the readOnly value to false.

Note: The function name setReadonly() also works.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
</tbody>
</table>
## Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>readOnly</td>
<td>Boolean</td>
<td>Flag that determines whether the associate field is editable or read-only.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Set field to read-only</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Set field to be editable</td>
</tr>
</tbody>
</table>

## GlideForm - setSectionDisplay(String sectionName, Boolean display)

Shows or hides a section.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sectionName</td>
<td>String</td>
<td>The section name is lower case with an underscore replacing the first space in the name, and with the remaining spaces being removed, for example &quot;Section Four is Here&quot; becomes &quot;section_fourishere&quot;. Other non-alphanumeric characters, such as ampersand (&amp;), are removed. Section names can be found by using the getSectionNames() method.</td>
</tr>
<tr>
<td>display</td>
<td>Boolean</td>
<td>When true shows the section. When false hides the section.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true when successful.</td>
</tr>
</tbody>
</table>
This method also supports setting values in a multi-row variable set (MRVS). You must first use `JSON.parse(getValue('<mrvs_field_name>'))` to obtain the MRVS array and then use indexing to update the fields within the row objects. Once all values are updated in the MRVS, use the `setValue()` method to save the updated MRVS array. For more details, see the code example below.

⚠️ **Note:** The method `setValue()` can cause a stack overflow when used in an OnChange client script. This is because every time the value is set, it will register as a change, which may re-trigger the OnChange client script. To prevent this, perform a check that will validate that the new value will be different from the old value. For example, before performing `setValue(shortDesc, newValue.toUpperCase());`, validate that the short description is not already uppercase. This will prevent the client script from applying the `toUpperCase()` more than once.

⚠️ **Note:** When defining a value in a choice list, be sure to use the number value rather than the label.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the form field to update.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>String value to set in the specified field.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to set the short description in the current form.

```javascript
  g_form.setValue('short_description', 'replace this with appropriate text');
```

The following example shows how to set values in an MVRS. In this example, salaries are being managed through the Service Catalog. The client script searches all rows within the MRVS for the value entered in the **Job title** and then updates the matching entries within the MVRS with what is entered in the **Salary** field. The MRVS is named "variable_set_1" and contains the following fields within each row object: Employee name [employee_name], Job title [employee_job_title], and Salary [employee_salary]. In addition, the Catalog Item contains: Job title [job_title] and Salary [salary].
function onChange(control, oldValue, newValue, isLoading) {
    if (isLoading || newValue == '') {
        return;
    }

    // Get the MRVS
    var multiRowVariableSet = JSON.parse(g_form.getValue('variable_set_1'));

    for (var i = 0; i < multiRowVariableSet.length; i++) {
        // Check if the entered job title matches the title in the current MRVS row
        if (multiRowVariableSet[i].employee_job_title == g_form.getValue("job_title")) {
            // Update the value of a matching field with the new salary
            multiRowVariableSet[i].employee_salary = newValue;
        }
    }

    // Update the MRVS
    g_form.setValue('variable_set_1', JSON.stringify(multiRowVariableSet));
}

GlideForm - setValue(String fieldName, String value, String displayValue)
Sets the value of a specified form field to the value of a specified display value in a reference record.

To improve performance by preventing a round trip when setting the value for a reference field, use this method, not setValue(fieldName, value). When setting multiple reference values for a list collector field, pass arrays in the value and displayValue parameters.

ℹ️ Note: The method `setValue()` can cause a stack overflow when used in an OnChange client script. This is because every time the value is set, it will register as a change, which may re-trigger the OnChange client script. To prevent this, perform a check that will validate that the new value will be different from the old value. For example, before performing `setValue(shortDesc, newValue.toUpperCase());`, validate that the short description is not already uppercase. This will prevent the client script from applying the `toUpperCase()` more than once.

ℹ️ Note: When defining a value in a choice list, be sure to use number value rather than the label.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the form field to update.</td>
</tr>
<tr>
<td>value</td>
<td>String or Array</td>
<td>Sys_id of the reference record to use to update the field. If the specified field is a GlideList, this parameter can contain an array of sys_ids. In this case, the method performs a lookup of all records specified in the array and those values are used to update the contents of the specified field (related list).</td>
</tr>
<tr>
<td>displayValue</td>
<td>String or Array</td>
<td>Field within the specified reference record to use to update the specified field. For example, in the User [sys_user] table it might be userName. If the specified field is a GlideList, this parameter can contain an array of display value names. For additional information on display values, see Display value.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows passing the sys_id of the reference record that contains the userName field to use to update the assigned_to form field.

```javascript
const userSysID = 'some sys_id';
const userName = 'some display value';
g_form.setValue('assigned_to', userSysID, userName);
```

This example shows passing an array of reference record sys_ids and an array of corresponding display value names to use to update the form fields in the GlideList glide-list_field_name.

```javascript
const sysIDArray = ['sys_id1', 'sys_id2'];
const displayNameArray = ['display_value1', 'display_value2'];
g_form.setValue('glide-list_field_name', sysIDArray, displayNameArray);
```

**GlideForm - setVisible(String fieldName, Boolean display)**

Displays or hides the field.

On desktop UI, the space is left blank when hidden. On Mobile or Service Portal UI, the space is filled in my other fields when hidden. This method cannot hide mandatory fields with no value.
Use UI Policy rather than this method whenever possible.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
<tr>
<td>display</td>
<td>Boolean</td>
<td>When true displays the field. When false hides the field.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
function onChange(control, oldValue, newValue, isLoading, isTemplate) {
  //If the page isn't loading
  if (!isLoading) {
    //If the new value isn't blank
    if (newValue != '') {
      g_form.setVisible('priority', false);
    }
    else
      g_form.setVisible('priority', true);
  }
}
```

**GlideForm - showErrorBox(String name, String message)**

Displays an error message under the specified form field (either a control object or the name of the field). If the control or field is currently off the screen, the form scrolls to the control or field.

A global property (glide.ui.scroll_to_message_field) is available that controls automatic message scrolling when the form field is off screen (scrolls the form to the control or field). The `showFieldMsg()` method is a similar method that requires a type parameter.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the control or field.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>The message to be displayed.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideForm - showErrorBox(String name, String message, Boolean scrollForm)**

Displays an error message under the specified form field (either a control object or the name of the field). If the control or field is currently off the screen and the scrollForm parameter is true, the form scrolls to the control or field.

A global property (glide.ui.scroll_to_message_field) is available that controls automatic message scrolling when the form field is off screen (scrolls the form to the control or field). The `showFieldMsg()` method is a similar method that requires a type parameter.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field or control.</td>
</tr>
<tr>
<td>message</td>
<td>String</td>
<td>Message to display.</td>
</tr>
<tr>
<td>scrollForm</td>
<td>Boolean</td>
<td>When true scrolls the form to the field. When false the form does not scroll to the field.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideForm - showFieldMsg(String field, String message, String type)**

Displays either an informational or error message under the specified form field (either a control object or the name of the field). If the control or field is off the screen, the form is scrolled to the field.
A global property (glide.ui.scroll_to_message_field) is available that controls automatic message scrolling when the form field is off screen (scrolls the form to the control or field).

The showErrorBox() method is a shorthand method that does not require the type parameter.

Note: This method does not work with the journal_field type field in UI16.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Name of the field or control.</td>
</tr>
<tr>
<td>message</td>
<td>String</td>
<td>Message to display.</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>&quot;error&quot;,&quot;info&quot;, or &quot;warning&quot;.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
g_form.showFieldMsg('impact','Low impact response time can be one week','info');
```

**GlideForm - showFieldMsg(String field, String message, String type, Boolean scrollForm)**

Displays either an informational or error message under the specified form field (either a control object or the name of the field). If the control or field is currently off the screen and scrollForm is true, the form is scrolled to the field.

A global property (glide.ui.scroll_to_message_field) is available that controls automatic message scrolling when the form field is off screen (scrolls the form to the control or field).

The showErrorBox() method is a shorthand method that does not require the type parameter.

Note: This method does not work with the journal_field type field in UI16.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Name of the field or control.</td>
</tr>
<tr>
<td>message</td>
<td>String</td>
<td>Message to display.</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>&quot;error&quot;, &quot;info&quot;, or &quot;warning&quot;.</td>
</tr>
<tr>
<td>scrollForm</td>
<td>Boolean</td>
<td>When true, the form scrolls to the field if it is off screen. When false, the form does not scroll.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
g_form.showFieldMsg('impact','Low impact not allowed with High priority','error',false);
```

#### GlideForm - showRelatedList(String listTableName)

Displays the specified related list on the form.

This method is not available on the mobile platform. If this method is run on a mobile platform, no action occurs.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>listTableName</td>
<td>String</td>
<td>Name of the related list.</td>
</tr>
</tbody>
</table>

### GlideForm - showRelatedLists()

Displays all the form's related lists.
This method is not available on the mobile platform. If this method is run on a mobile platform, no action occurs.

### GlideForm - submit()
Saves the record.
The user is taken away from the form, returning them to where they were.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### GlideForm - submit(String verb)
Performs the UI action specified by the parameter.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>verb</td>
<td>String</td>
<td>An action_name from a sys_ui_action record. The action name must be for a visible form button.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Mobile GlideForm (g_form) - Client**

Mobile GlideForm (g_form) methods enable you to work with forms on the mobile platform.

Use these methods in any script that targets a mobile device.

**MobileGlideForm (g_form) - addDecoration(String fieldName, String icon, String text)**

Adds a decorative icon next to a field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
<tr>
<td>icon</td>
<td>String</td>
<td>The font icon to show next to the field.</td>
</tr>
<tr>
<td>text</td>
<td>String</td>
<td>The text title for the icon (used for screen readers).</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example adds a VIP icon next to the caller.

```javascript
function onChange(control, oldValue, newValue, isLoading) {
    // if the caller_id field is not present, then we can't add an icon anywhere
    if (!g_form.hasField('caller_id'))
        return;

    if (!newValue)
        return;

    g_form.getReference('caller_id', function(ref) {
```
g_form.removeDecoration('caller_id', 'icon-star', 'VIP');

if (ref.getValue('vip') == 'true')
    g_form.addDecoration('caller_id', 'icon-star', 'VIP');
});
}

**MobileGlideForm (g_form) - getLabel(String fieldName)**

Gets the form label text.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The label text.</td>
</tr>
</tbody>
</table>

if (g_user.hasRole('itil')) {
    var oldLabel = g_form.getLabel('comments');
    g_form.setLabel('comments', oldLabel + ' (Customer visible)');
}

**MobileGlideForm (g_form) - hasField(String fieldName)**

Determines if a field is present on the form.

Present means that it can be shown, not that it is visible.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field to look for.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the field is present on the form; false, if it is not. On the form means that the field is part of g_form. It could still be hidden, read-only, mandatory, or invalid.</td>
</tr>
</tbody>
</table>

This example makes the assigned_to field mandatory if the assignment_group field is on the form.

```javascript
if (g_form.hasField('assignment_group'))
    g_form.setMandatory('assigned_to', true);
```

**MobileGlideForm (g_form) - removeDecoration(String fieldName, String icon, String text)**

Removes a decorative icon from next to a field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
<tr>
<td>icon</td>
<td>String</td>
<td>The icon to remove.</td>
</tr>
<tr>
<td>text</td>
<td>String</td>
<td>The text title for the icon.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
function onChange(control, oldValue, newValue, isLoading) {
    // if the caller_id field is not present, then we can't add an icon anywhere
    if (!g_form.hasField('caller_id'))
        return;
    if (!newValue)
        return;
```
```javascript
function onBeforeLoad() {
  g_form.getReference('caller_id', function(ref) {
    g_form.removeDecoration('caller_id', 'icon-star', 'VIP');

    if (ref.getValue('vip') == 'true') {
      g_form.addDecoration('caller_id', 'icon-star', 'VIP');
    }
  });
}
```

**MobileGlideForm (g_form) - setLabel(String fieldName, String label)**

Sets the form label text.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
<tr>
<td>label</td>
<td>String</td>
<td>The field label text.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example changes the comments label.

```javascript
if (g_user.hasRole('itil')) {
  var oldLabel = g_form.getLabel('comments');
  g_form.setLabel('comments', oldLabel + ' (Customer visible)');
}
```

**GlideFormScratchpad - Scoped, Client**

The scoped GlideFormScratchpad class implements the g_scratchpad object for scoped applications.

The scoped GlideFormScratchpad class has no constructor and no methods. The g_scratchpad object behaves identically for global and scoped applications.

The g_scratchpad object provides a mechanism for passing information from the server to the client when the client requires information not available on a form. This can be accomplished by creating a business rule to put the information in the g_scratchpad object and accessing the information in a client script.
For an example on using this class, Example: g_scratchpad on the Developer Site.

**GlideGuidV3 - Client**
You can create a globally unique identifier.
You access the GlideGuidV3 methods using the g_guid global object.

**GlideGuidV3 - generate(Number stringLength)**
Creates a globally unique identifier 32 characters long, or as specified with the optional length argument.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stringLength</td>
<td>Number</td>
<td>The desired string length, must be between 1 and 32 inclusive. This parameter is optional. If not specified, the returned string will be 32 characters long.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The globally unique identifier.</td>
</tr>
</tbody>
</table>

**GlideHTTPRequest - Global**
Utility methods to perform common functions with Glide HTTP requests.
Use GlideHTTPRequest in global server-side scripts. To use this class, instantiate a GlideHTTPRequest object using the constructor. The constructor requires an endpoint URL as an input parameter.

**GlideHTTPRequest - addHeader(String name, String value)**
Add a header to your HTTP request.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The header name</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The header value</td>
</tr>
</tbody>
</table>
GlideHTTPRequest - addParameter(String name, String value)
Add a parameter to your HTTP request.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The header name</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The header value</td>
</tr>
</tbody>
</table>

GlideHTTPRequest - executeMethod(HttpMethod method)
Executes the method defined in the parameter.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>method</td>
<td>HttpMethod</td>
<td>Choose an HTTP method</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Delete</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Fetch</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Get</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Post</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Put</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>The status value.</td>
</tr>
</tbody>
</table>
**GlideHTTPRequest - getErrorMessage()**

Returns the last error encountered.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Returns a text string that describes the last error encountered</td>
</tr>
</tbody>
</table>

**GlideHTTPRequest - setBasicAuth(String userName, String password)**

Set a user name and password for basic authentication.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>userName</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>password</td>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideHTTPRequest - setContentType(String type)**

Set the content type for your HTTP request.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>The content type.</td>
</tr>
</tbody>
</table>
### GlideHTTPRequest - setFollowRedirect(boolean followRedirect)
Enable or disable the follow redirect option.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>followRedirect</td>
<td>Boolean</td>
<td>This value is true by default. Set to false to prevent following redirects.</td>
</tr>
</tbody>
</table>

### GlideHTTPRequest - setHttpTimeout(int timeout)
Set the HTTP timeout value in milliseconds.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeout</td>
<td>Integer</td>
<td>The timeout in milliseconds.</td>
</tr>
</tbody>
</table>

### GlideHTTPRequest - setLogLevel(String logLevel)
Set the log level for HTTP requests.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logLevel</td>
<td>String</td>
<td>The level of logging available. Choose from one of the following values.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>• basic</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• elevated</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• all</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideHTTPRequest - setupProxy(String host, String port)**

Set the proxy host and port.

Additional information about the method that does not belong in the short description.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>String</td>
<td>The proxy host</td>
</tr>
<tr>
<td>port</td>
<td>String</td>
<td>The proxy port</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideHTTPResponse**

Utility methods to perform common functions with Glide HTTP responses.

**GlideHTTPResponse - getAllHeaders()**

Returns a list of all headers.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>List&lt;IHTTPHeader&gt;</td>
<td>A list containing all headers.</td>
</tr>
</tbody>
</table>

GlideHTTPResponse - getBody()

Returns a string containing a body for the HTTP response.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The HTTP response body.</td>
</tr>
</tbody>
</table>

Note: If the stream has already been accessed, it cannot be accessed again. In this case the method will return null.

GlideHTTPResponse - getCookies()

Returns a list containing the cookies for the HTTP response.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>List&lt;String&gt;</td>
<td>A list containing the name and value of each cookie as a string.</td>
</tr>
</tbody>
</table>
**GlideHTTPResponse - getErrorCode()**

Return the current error code.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Integer</td>
</tr>
</tbody>
</table>

**GlideHTTPResponse - getHeader(String name)**

Returns the header specified in the parameter.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>name</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

**GlideHTTPResponse - getHeaders()**

Returns a map of headers.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Map</td>
</tr>
</tbody>
</table>
GlideHTTPResponse - getHttpMethod()

Returns the HTTP method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HttpMethod</td>
<td>The HTTP method (GET, POST, etc).</td>
</tr>
</tbody>
</table>

GlideHTTPResponse - getStatusCode()

Returns the last status code.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>Returns the HTTP response status code.</td>
</tr>
</tbody>
</table>

GlideHTTPResponse - haveError()

Returns true if an error has occurred.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if an error has occurred, or false if there are no errors</td>
</tr>
</tbody>
</table>
**GlideImpersonate - Global**

The global GlideImpersonate API enables administrators to pose as another authenticated user for testing purposes.

Use the GlideImpersonate API when you need to act as another user so to test functionality within your application. When impersonating another user, the administrator has access to exactly what the impersonated user would have access to in the system, including the same menus and modules.

⚠️ **Note:** The system records anything the administrator does while impersonating another user as having been done by that user.

**GlideImpersonate - canDebug(String userSysId)**

Verifies whether the specified user can perform debugging on scripts.

In order for a user to be able to debug scripts, they must be on a developer instance. Debugging is not allowed on production instances.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>userSysId</td>
<td>String</td>
<td>sys_Id of the user to verify for debugging capability.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True: User is able to debug the application.</td>
</tr>
<tr>
<td>False: User is not able to debug the application.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
userDebug: function(userId) {
  var impUser = new GlideImpersonate();
  impUser.canDebug(userId);
}
```

**GlideImpersonate - canImpersonate(String userSysId)**

Verifies whether the current user can impersonate the specified user.
If the current user is not assigned the admin role, the user to impersonate is inactive, or there are other issues with impersonating the specified user, the method returns "false" and the user cannot be impersonated.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>userSysId</td>
<td>String</td>
<td>sys_Id of the user to impersonate</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the current user can impersonate the specified user. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Current user can impersonate the specified user.</td>
</tr>
<tr>
<td></td>
<td>• false: Current user cannot impersonate the specified user.</td>
</tr>
</tbody>
</table>

```javascript
function onlineImpersonate(userSysId) {
  if (!GlideImpersonate().canImpersonate(userSysId)){
    gs.addInfoMessage("No access to impersonate " + userSysId);
  } else {
    GlideImpersonate().impersonate(userSysId);
  }
  return;
}
```

### GlideImpersonate - impersonate(String userSysId)

Sets the user ID for the current administrator to the passed-in user ID, enabling the administrator to act as that user.

When impersonating another user, the administrator has access to exactly what the impersonated user would have access to in the system, including the same menus and modules. Only use this method when testing functionality in an application. Ensure that once you are finished impersonating a user that you call the method again with the administrator sys_Id to stop the impersonation.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>userSysId</td>
<td>String</td>
<td>Sys_id of the user to impersonate.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the user that was logged in prior to the impersonation request.</td>
</tr>
</tbody>
</table>

The following example shows how to get the current user object.

```javascript
var user = gs.getUserDisplayName();
gs.print("The current user display name is: " + user);

var impUser = new GlideImpersonate();
impUser.impersonate("62826bf03710200044e0bfc8bcbe5df1");
var user = gs.getUserDisplayName();
gs.print("The impersonated user display name is: " + user);
```

Output:

```
The current user display name is: System Administrator
The impersonated user display name is: Abel Tuter
```

### GlideImpersonate - isImpersonating()

Determines whether the current user is impersonating another user.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True: User is currently impersonating another user.</td>
</tr>
<tr>
<td></td>
<td>False: User is not currently impersonating another user.</td>
</tr>
</tbody>
</table>
function abortOnImpersonate() {
  if (GlideImpersonate().isImpersonating()){
    current.setAbortAction(true);
    gs.addInfoMessage("Transaction canceled due to Impersonation");
  }
  return;
}

**GlideImportLog - Scoped, Global**

Writes log entries directly to the Import Log `[import_log]` table.

A GlideImportLog object consumable by the GlideImportSetTransformer API. This object is not required for the GlideImportSetTransformer API, it enables you to associate import logs with a specific Import Set transformation.

**Related information**

- GlideImportSetRun
- GlideImportSetTable
- GlideImportSetTransformer
- GlideImportSetTransformMap
- GlideTransformLog

**GlideImportLog - error(String message, String source)**

Logs a message of type Error to the Import Log `[import_log]` table.

**GlideImportLog**

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Log message. Maximum length 4000 characters.</td>
</tr>
<tr>
<td>source</td>
<td>String</td>
<td>Optional. Source field value attached to the Import Log record that defines where in the Import Set process this message was logged from. For example, Loading could represent loading step, Cleanup could represent during the cleanup after the transform, and so on.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```
var importLog = new GlideImportLog();
importLog.error('Error executing transform');
```

GlideImportLog - getImportRunHistory()

Returns a sys_id of the Import Run record associated with this Import Log.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of an Import Set Run record from the Transform History [sys_import_set_run] table.</td>
</tr>
</tbody>
</table>

```
var importSet = new GlideRecord('sys_import_set');
importSet.name = 'Scripted Import Set';
importSet.short_description = 'Import set from scripted rest api';
importSet.table_name = importSetTableName;
var importSetID = importSet.insert();
var importLog = new GlideImportLog();
var transformer = new GlideImportSetTransformer();
transformer.setLogger(importLog);
transformer.transformAllMaps(importSet);
var importRunSysId = importLog.getImportRunHistory();
```

GlideImportLog - GlideImportLog(GlideImportSetRun importSetRun, String source)

Instantiates a GlideImportLog object.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>importSetRun</td>
<td>GlideImportSetRun</td>
<td>Optional. Import Set Run record on which all logs are to be associated with.</td>
</tr>
<tr>
<td>source</td>
<td>String</td>
<td>Optional. Source field value attached to the Import Log record that defines where in the Import Set process this message was logged from. For example, Loading could represent loading step, Cleanup could represent during the cleanup after the transform, and so on.</td>
</tr>
</tbody>
</table>

Example without optional source parameter.

```javascript
var importSetRun = new GlideImportSetRun();
var importLog = new GlideImportLog(importSetRun);
```

Example using optional source parameter.

```javascript
var importSetRun = new GlideImportSetRun();
var importLog = new GlideImportLog(importSetRun, 'Scripted ImportSetTransformer');
```

GlideImportLog - info(String message, String source)

Logs a message of type Info to the Import Log [import_log] table.

GlideImportLog

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Log message. Maximum length 4000 characters.</td>
</tr>
<tr>
<td>source</td>
<td>String</td>
<td>Optional. Source field value attached to the Import Log record that defines where in the Import Set process this message was logged from. For example, Loading could represent loading step, Cleanup could represent during the cleanup after the transform, and so on.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importLog = new GlideImportLog();
importLog.info('Successfully executed transform');
```

**GlideImportLog - setImportRunHistory(String importRunHistory)**

Associates the GlideImportLog object with a specific Import Set Run record.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>importRunHistory</td>
<td>String</td>
<td>The sys_id of a record from the Transform History [sys_import_set_run] table.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importRunSysId = '4aa3a8d55ba10010953330ad5981c79f';
var importLog = new GlideImportLog();
importLog.setImportRunHistory(importRunSysId);
```

**GlideImportLog - warn(String message, String source)**

Logs a message of type Warn to the Import Log [import_log] table.

**GlideImportLog**

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Log message. Maximum length 4000 characters.</td>
</tr>
<tr>
<td>source</td>
<td>String</td>
<td>Optional. Source field value attached to the Import Log record that defines where in the Import Set process this message was logged from. For example, Loading could</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>represent loading step, Cleanup could represent during the cleanup after the transform, and so on.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importLog = new GlideImportLog();
importLog.warn('Transform taking longer than expected.');
```

**GlideImportSetRun - Scoped, Global**

Creates an Import Set Run record which can be consumed by the GlideImportSetTransformer API.

**Related information**

- GlideImportLog
- GlideImportSetTable
- GlideImportSetTransformer
- GlideImportSetTransformMap
- GlideTransformLog

**GlideImportSetRun - getImportSetRunSysID()**

Gets the sys_id of the Import Set Run associated with the transformation.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>String</td>
<td>The sys_id of the Transform Histories [sys_import_set_run] record associated with the transform.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importSetRun = new GlideImportSetRun();
var importSetRunSysId = importSetRun.getImportSetRunSysID();
```

**GlideImportSetRun - GlideImportSetRun(String importSetID)**

Instantiates a GlideImportSetRun object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>importSetID</td>
<td>String</td>
<td>Optional. The sys_id of the import set record listed in the Import Sets [sys_import_set] table. If not set, a new [sys_import_set] record is created and the GlideImportSetRun object represents this record.</td>
</tr>
</tbody>
</table>

```javascript
var importSetRun = new GlideImportSetRun();
```

**GlideImportSetTable - Scoped, Global**

The GlideImportSetTable API provides methods to create temporary Import Set tables.

These methods create the Import Set table using a dynamic, standard naming convention. Tables must have at least one defined column. Modification and deletion of existing Import Set tables is not supported.

A scheduled job named Scripted Import Set Deleter runs every seven days by default. Scripted Import Set Deleter deletes all Import Sets, Transform Maps, Transform Entries, and drops the Import Set Tables associated with the tables created by this API.

You can use the GlideImportSetTable methods in global and scoped scripts. Use the `sn_impex` namespace identifier to create a GlideImportSetTable object.

GlideTransformLog

**GlideImportSetTable - GlideImportSetTable(String tableLabel)**

Instantiates a GlideImportSetTable object.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableLabel</td>
<td>String</td>
<td>Label of the Import Set table created upon calling the <code>create()</code> method.</td>
</tr>
</tbody>
</table>

```javascript
var importSetTable = new sn_impex.GlideImportSetTable("temp user table");
```

**GlideImportSetTable - addDateTimeColumn(String columnLabel)**

Creates a GlideDateTime column.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnLabel</td>
<td>String</td>
<td>Label of the GlideDateTime column to create in the Import Set table.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importSetTable = new sn_impex.GlideImportSetTable("temp user table");
importSetTable.addDateTimeColumn('start date');
var tableStructure = importSetTable.create();
```

**GlideImportSetTable - addStringColumn(String columnLabel, Number length)**

Creates a string column.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnLabel</td>
<td>String</td>
<td>Label of the string column to create in the Import Set table.</td>
</tr>
<tr>
<td>length</td>
<td>Number</td>
<td>Optional. Maximum column length. Default: 40 characters</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importSetTable = new sn_impex.GlideImportSetTable("temp user table");
importSetTable.addStringColumn('first name', 50);
importSetTable.addStringColumn('last name', 50);
var tableStructure = importSetTable.create();
```

### GlideImportSetTable - create()

Creates the Import Set table.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>JSON object in the following format:</td>
</tr>
<tr>
<td></td>
<td>• tableName: String. Database name of the table.</td>
</tr>
<tr>
<td></td>
<td>• columns: Object. Map of table column labels to column names provided by</td>
</tr>
<tr>
<td></td>
<td>the addDateTimeColumn() and addStringColumn() methods.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column_label</td>
<td>String. Label of the string column in the Import Set table.</td>
</tr>
<tr>
<td>column_name</td>
<td>String. Name of the string column in the Import Set table.</td>
</tr>
</tbody>
</table>

```javascript
// Create Import Set table
var importSetTable = new sn_impex.GlideImportSetTable("temp user table");
importSetTable.addStringColumn('first name', 40);
importSetTable.addStringColumn('last name', 40);
importSetTable.addDateTimeColumn('start date');
var tableStructure = importSetTable.create();

/*
tableStructure = {
"tableName": "imp_staging_table_1417601730000",
"tableLabel": "temp user table",
"columns": {
    "first name": "u_first_name",
    "last name": "u_last_name",
    "start date": "u_start_date"
}
}
*/
var importSetTableName = tableStructure['tableName'];
var columns = tableStructure['columns'];
```

**GlideImportSetTransformer - Scoped, Global**

Creates an Import Set Transformer object used to execute an Import Set Transform.

To execute an Import Set transform:

1. Create an Import Set table using the `GlideImportSetTable` API.
2. Create a Transform Map using the `GlideImportSetTransformMap` API.
3. Create or use an existing Import Set using the GlideRecord API.

4. Execute an Import Set Transform using the GlideImportSetTransformer API.

Once you have created the Import Set record it must be consumed by the GlideImportSetTransformer API in order to trigger the transform.

```javascript
var transformer = new GlideImportSetTransformer();
transformer.transformAllMaps(importSetGr);
```

**Related information**

- GlideImportLog
- GlideImportSetRun
- GlideImportSetTable
- GlideImportSetTransformMap
- GlideRecord
- GlideTransformLog

**GlideImportSetTransformer - GlideImportSetTransformer()**

Instantiates a GlideImportSetTransformer object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var transformer = new GlideImportSetTransformer();
```

**GlideImportSetTransformer - getImportSetRun()**

Gets the Import Set Run object associated with a GlideImportSetTransformer object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>GlideImportSetRun</td>
<td>GlideImportSetRun object created by running a transformation or the argument supplied to the setImportSetRun() method.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importSet = new GlideRecord('sys_import_set');
importSet.short_description = 'Import set from scripted rest api';
importSet.table_name = importSetTableName;
var importSetID = importSet.insert();
var transformer = new GlideImportSetTransformer();
transformer.transformAllMaps(importSet);
var importSetRun = transformer.getImportSetRun();
```

**GlideImportSetTransformer - isError()**

Returns a Boolean value specifying whether or not there was an error during a transformation.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether there is an error.</td>
</tr>
<tr>
<td></td>
<td>• true: Error.</td>
</tr>
<tr>
<td></td>
<td>• false: Success.</td>
</tr>
</tbody>
</table>

```javascript
var importSet = new GlideRecord('sys_import_set');
importSet.short_description = 'Import set from scripted rest api';
importSet.table_name = importSetTableName;
var importSetID = importSet.insert();
var transformer = new GlideImportSetTransformer();
transformer.transformAllMaps(importSet);
if(transformer.isError()) {
```

GlideImportSetTransformer - setImportSetID(String id)

Associates an Import Set record with a specific GlideImportSetTransformer object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>The sys_id of an Import Set record from the Import Sets [sys_import_set] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importSet = new GlideRecord('sys_import_set');
importSet.short_description = 'Import set from scripted rest api';
importSet.table_name = importSetTableName;
var importSetID = importSet.insert();
var transformer = new GlideImportSetTransformer();
transformer.setImportSetID(importSetID);
transformer.transformAllMaps(importSet);
```

GlideImportSetTransformer - setImportSetRun(GlideImportSetRun importSetRun)

Associates an Import Set Run object with a specific GlideImportSetTransformer object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>importSetRun</td>
<td>GlideImportSetRun</td>
<td>GlideImportSetRun object representing the ImportSetRun record to track the transformation history.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importSet = new GlideRecord('sys_import_set');
importSet.short_description = 'Import set from scripted rest api';
importSet.table_name = importSetTableName;
var importSetID = importSet.insert();
var importSetRun = new GlideImportSetRun(importSetID);
var transformer = new GlideImportSetTransformer();
transformer.setImportSetRun(importSetRun);
transformer.transformAllMaps(importSet);
```

**GlideImportSetTransformer - setLogger(GlideImportLog log)**

Associates a GlideImportLog object with a specific GlideImportSetTransformer object.

If this method is not called prior to calling the `transformAllMaps()` method, a GlideImportLog object is created internally on the server side.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log</td>
<td>GlideImportLog</td>
<td>GlideImportLog object to link to the Import Set history. Once set, any call from the GlideImportLog object is associated with the Import Set run history for that specific transform.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importSet = new GlideRecord('sys_import_set');
importSet.short_description = 'Import set from scripted rest api';
importSet.table_name = importSetTableName;
var importSetID = importSet.insert();
var importLog = new GlideImportLog();
```
```javascript
var transformer = new GlideImportSetTransformer();
transformer.setLogger(importLog);
transformer.transformAllMaps(importSet);
```

**GlidelImportSetTransformer - setMapID(String mapID)**

Associates a Transform Map with a specific GlidelImportSetTransformer object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mapID</td>
<td>String</td>
<td>A sys_id from the Table Transform Maps [sys_transform_map] table.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importSet = new GlideRecord('sys_import_set');
importSet.short_description = 'Import set from scripted rest api';
importSet.table_name = importSetTableName;
var importSetID = importSet.insert();
var transformMapId = '<sys id of transform map>';
var transformer = new GlidelImportSetTransformer();
transformer.setMapID(transformMapId);
transformer.transformAllMaps(importSet);
```

**GlidelImportSetTransformer - setSyncImport(Boolean synchronous)**

Enables running synchronous transformations.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>synchronous</td>
<td>Boolean</td>
<td>Sets transformation mode. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Run transformation synchronously</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Run transformation asynchronously</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Default: false</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var importSet = new GlideRecord('sys_import_set');
importSet.short_description = 'Import set from scripted rest api';
importSet.table_name = importSetTableName;
var importSetID = importSet.insert();
var transformer = new GlideImportSetTransformer();
transformer.setSyncImport(True);
transformer.transformAllMaps(importSet);
```

GlideImportSetTransformer - transformAllMaps(GlideRecord importSet, String rowSysId)

Executes the Import Set transformation.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>importSet</td>
<td>GlideRecord</td>
<td>GlideRecord of the import set to execute.</td>
</tr>
<tr>
<td>rowSysId</td>
<td>String</td>
<td>Optional. Restricts transformation to a single record by passing the sys_id of a record from the Import Sets [sys_import_set] table. Default: Transform all rows</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
```javascript
var importSet = new GlideRecord('sys_import_set');
importSet.short_description = 'Import set from scripted rest api';
importSet.table_name = importSetTableName;
var importSetID = importSet.insert();
var transformer = new GlideImportSetTransformer();
transformer.transformAllMaps(importSet);
```

GlideImportSetTransformMap - Scoped, Global

Provides methods to create transform maps and transform entries.

You can use the GlideImportSetTransformMap methods in global and scoped scripts. Use the sn_impex namespace identifier to create a GlideImportSetTransformMap object.

Related information

- GlideImportLog
- GlideImportSetRun
- GlideImportSetTable
- GlideImportSetTransformer
- GlideTransformLog

GlideImportSetTransformMap - addDateTimeTransformEntry(String sourceColumn, String targetColumn, Boolean coalesce, String dateTimeFormat)

Add a GlideDateTime transform entry to a transform map.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetColumn</td>
<td>String</td>
<td>Target column from target table to transform to.</td>
</tr>
</tbody>
</table>
| coalesce       | Boolean | Optional. Flag that indicates whether to insert the record into the target table
|                |         | • true: If true and target table contains a record with the same value in this field, the record is updated, that is, not inserted. |
|                |         | • false: Default. Record is inserted into the target table.                  |
| sourceColumn   | String  | Source column from Import Set table to transform from.                      |

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dateTimeFormat</td>
<td>String</td>
<td>Optional. GlideDateTime format of the transform, for example, yyyy-MM-dd HH:mm:ss. If empty, the default value is the system date time format.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var transformMap = new sn_impex.GlideImportSetTransformMap("temp user map name", importSetTableName, targetTableName,);
transformMap.addDateTimeTransformEntry("u_start date", "first day", true, "yyyy-MM-dd HH:mm:ss");
var transformMapId = transformMap.create();
```

**GlideImportSetTransformMap - addTransformEntry(String sourceColumn, String targetColumn, Boolean coalesce)**

Adds a string transform entry to a transform map.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>targetColumn</td>
<td>String</td>
<td>Source column from Import Set table to transform from.</td>
</tr>
<tr>
<td>coalesce</td>
<td>String</td>
<td>Target column from target table to transform to.</td>
</tr>
<tr>
<td>sourceColumn</td>
<td>Boolean</td>
<td>Optional. Flag that indicates whether to insert the record into the target table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: If true and target table contains a record with the same value in this field, the record is updated, that is, not inserted.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Default. Record is inserted into the target table.</td>
</tr>
</tbody>
</table>
GlideImportSetTransformMap - create()
Creates a new transform map.

Important: To create a transform map you must have defined at least one transform entry using either `addDateTimeTransformEntry()` or `addTransformEntry()`.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The sys_id of the created transform map.</td>
</tr>
</tbody>
</table>

GlideImportSetTransformMap - GlideImportSetTransformMap(String transformMapName, String importSetTableName, String targetTableName)
Instantiates a GlideImportSetTransformMap object.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transformMapName</td>
<td>String</td>
<td>Name of the map.</td>
</tr>
<tr>
<td>importSetTableName</td>
<td>String</td>
<td>Name of the Import Set table.</td>
</tr>
<tr>
<td>targetTableName</td>
<td>String</td>
<td>Name of the target table.</td>
</tr>
</tbody>
</table>

```javascript
var transformMap = new sn_impex.GlideImportSetTransformMap("temp user map name", importSetTableName, targetTableName);
```

### GlideList2 (g_list) - Client

GlideList2 is a JavaScript class used to customize (v2) lists.

The variable `g_list` is used to access a specified list object. The `g_list` variable is not available to the related lists form link UI action. It is available to the lists form link UI action.

These methods are used in UI Context Menus and UI Actions.

#### GlideList2 - addFilter(String filter)

Adds a single term to the list query filter.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filter</td>
<td>String</td>
<td>Query string condition to add.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
g_list.addfilter("active=true");
```

### GlideList2 - get(Object DOMelement)

Returns the GlideList2 object for the list that contains the specified item.
### GlideList2 - `get(String ListID)`

Returns the `GlideList2` object for the list specified.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ListID</td>
<td>String</td>
<td>The list ID for which you want the <code>GlideList2</code> object.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The GlideList2 object or null if not found.</td>
</tr>
</tbody>
</table>

```javascript
function assignLabelActionViaLookupModal(tableName, listId) {
  var list = GlideList2.get(listId);
  if (!list)
    return;

  assignLabelViaLookup(tableName, sysIds, list.getView());
}
```

### GlideList2 - `getChecked()`

Returns a comma-separated list of the sys_ids for the items that are checked in the list.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Comma-separated list of the sys_ids for the items that are checked in the list. Does not check to determine that the items returned are allowed to be executed.</td>
</tr>
</tbody>
</table>

```javascript
function removeLabelActionViaLookupModal(tableName, listId) {
    var list = GlideList2.get(listId);
    if (!list)
        return;
    var sysIds = list.getChecked();
    if (!sysIds)
        return;
    removeLabelViaLookup(tableName, sysIds);
}
```

**GlideList2 - getFixedQuery()**

Returns the sysparm_fixed query.

A fixed query is the part of the query that cannot be removed from the breadcrumb (i.e., it is fixed for the user). It is specified by including a `sysparm_fixed_query` parameter for the application module.
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The fixed query string for the list.</td>
</tr>
</tbody>
</table>

```javascript
var list = GlideList2.get(container.readAttribute('list_id'));
var filter = this._getFilter(element);
var fixedQuery = list.getFixedQuery();
if (fixedQuery)
    filter += '^' + filter;
```

**GlideList2 - getGroupBy()**

Returns the field or comma-separated list of fields that are used to group the list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>none</td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The field or comma-separated list of fields that are used to group the list.</td>
</tr>
</tbody>
</table>

```javascript
function runFilterV2Lists(name, filter) {
    var list = GlideList2.get(name);
    if (list) {
        var groupBy = list.getGroupBy();
        if (groupBy)
            filter += '^' + groupBy;

        list.setFilterAndRefresh(filter);
    }
}
```

**GlideList2 - getListName()**

Returns the name of the list, which is usually the table name.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The list name (usually the table name).</td>
</tr>
</tbody>
</table>

```
var list = GlideList2.get(name);
var listName = list.getListName();
```

GlideList2 - getOrderBy()

Returns the first field used to order the list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The field used for order, or a blank.</td>
</tr>
</tbody>
</table>

```
var list = GlideList2.get(listId);
if (!list)
  return;
var orderBy = list.getOrderBy();
```

GlideList2 - getParentTable()

Returns the name of the parent table for a related list (the table associated with the form).
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The parent table name.</td>
</tr>
</tbody>
</table>

for (var id in GlideLists2) {
  var list = GlideLists2[id];
  if (list.getName() == listTableName && list.getContainer() == tableName)
    return list.getContainer();
}

GlideList2 - getQuery(Boolean orderBy, Boolean groupBy, Boolean fixed, Boolean all)

Returns the encoded query string for the list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orderBy</td>
<td>Boolean</td>
<td>(Optional) If true, includes the orderBy in the encoded query string.</td>
</tr>
<tr>
<td>groupBy</td>
<td>Boolean</td>
<td>(Optional) If true, includes the groupBy in the encoded query string.</td>
</tr>
<tr>
<td>fixed</td>
<td>Boolean</td>
<td>(Optional) If true, includes fixed query in the encoded query string.</td>
</tr>
<tr>
<td>all</td>
<td>Boolean</td>
<td>(Optional) If true, includes orderBy, groupBy, and fixed query.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Encoded query string for the list.</td>
</tr>
</tbody>
</table>
```
var list = GlideList2.get(this.listID);
var ajax = new GlideAjax("AJAXJellyRunner", "AJAXJellyRunner.do");
   ajax.addParam("sysparm_query_encoded", list.getQuery({groupby: true, orderby: true}));
   ajax.addParam("sysparm_table", list.getTableName());
   ajax.addParam("sysparm_view", list.getView());
```

**GlideList2 - getRelated()**

Returns the related list field that associates the related list to the parent form.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Field that connects the list to the parent form.</td>
</tr>
</tbody>
</table>

```
var list = GlideList2.get(name);
var related = list.getRelated();
if (related)
   ajax.addParam("sysparm_is_related_list", "true");
```

**GlideList2 - getTableName()**

Returns the table name for the list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Returns the table name for the list.</td>
</tr>
</tbody>
</table>

GlideList2.getListsForTable = function(table) {
    var lists = [];
    for (var id in GlideLists2) {
        var list = GlideLists2[id];
        if (list.getTableName() == table)
            lists.push(list);
    }
    return lists;
}

GlideList2 - getView()

Returns the view used to display the list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>none</td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The name of the view.</td>
</tr>
</tbody>
</table>

function assignLabelActionViaLookupModal(tableName, listId) {
    var list = GlideList2.get(listId);
    if (!list)
        return;
    assignLabelViaLookup(tableName, sysIds, list.getView());
}
GlideList2 - getTitle()

Returns the list title.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The list title.</td>
</tr>
</tbody>
</table>

```javascript
var list = GlideList2.get(name);
var listTitle = list.getTitle();
```

GlideList2 - isUserList()

Returns true if the list has been personalized by the user by choosing the list mechanic and changing the list layout.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the list layout has been changed.</td>
</tr>
</tbody>
</table>

```javascript
var list = GlideList2.get(listId);
if (!list)
  return;
if (list.isUserList())
  var tableName = list.getTableName();
```
GlideList2 - refresh(Number firstRow, String additionalParms)

Refreshes the list. The **orderBy** part of the list filter is ignored so that the list uses its natural ordering when it is refreshed.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>firstRow</td>
<td>Number</td>
<td>(Optional) The first row to appear in the list. If not specified, the first row of the current is used.</td>
</tr>
<tr>
<td>additionalParms</td>
<td>String</td>
<td>(Optional) name-value pairs that are submitted with the list refresh request.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
$timeout(function() {
  if (GlideList.lists) {
    var list = GlideList.get(name);
    if (list) {
      if (sortBy) {
        if (sortDirection == 'ASC')
          list.sort(sortBy);
        else
          list.sortDescending(sortBy);
      }
      list.refresh();
    }
  }
})
```

GlideList2 - refreshWithOrderBy(Number firstRow, String description)

Refreshes the list. The **orderBy** part of the list filter is included if it is specified for the list.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>firstRow</td>
<td>Number</td>
<td>(Optional) The first row to appear in the list.</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>(Optional) name=value pairs that are submitted with the list refresh request.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
ga.getXML(function(serverResponse) {
  var response = serverResponse.responseXML.getElementsByTagName("response")[0];
  if (response) {
    var list = GlideList2.getByName("backlog_stories");
    list.refreshWithOrderBy();
    var status = response.getAttribute('status');
    $j('html, body').animate({scrollTop: $j("#"+data.record.sys_id).offset().top}, 500);
    if (status == 'failure') {
      alert('${gs.getMessage("Story cannot be created. Team is not associated with any project.")}');
    }
  }
});
```

GlideList2 - setFilter(String filter)

Sets the encoded query string for the list, ignoring the `orderBy` and `groupBy` parts of the query string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filter</td>
<td>String</td>
<td>Encoded query string.</td>
</tr>
</tbody>
</table>
null

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
list = GlideList2.get($(side+"ContentDivRelease").select(".list_div")[0].getAttribute("id"));
if (list) {
    list.setFilter("active=true");
    list.refresh(1);
}
```

**GlideList2 - setFilterAndRefresh(String filter)**

Sets the encoded query string for the list, including the `orderBy` and `groupBy` if specified, and then refreshes the list using the new filter.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filter</td>
<td>String</td>
<td>Encoded query string.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
function updateListFilter(projectID) {
    var list = GlideList2.getByName("backlog_stories");
    var fixedQuery = $('hdn_additional_filters').value;
    if(!projectID) {
        list.setFilterAndRefresh(fixedQuery + `ORDERBYteam_index`);
        list.setOrderBy("team_index");
    }
}
```

**GlideList2 - setFirstRow(Number rowNum)**

Sets the first row that appears in the list when the list is refreshed.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rowNum</td>
<td>Number</td>
<td>Row number of the first row to display.</td>
</tr>
</tbody>
</table>

Returs

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var nextRow = 0;
var rowsPerPage = 20;
var list = GlideList2.get(listId);
if (!list)
    return;
list.setFirstRow(nextRow);
nextRow = nextRow + rowsPerPage;
```

GlidleSt2 - setGroupBy(String groupBy)

Sets the list **groupBy** criteria for a single field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupBy</td>
<td>String</td>
<td>Optional. The <strong>groupBy</strong> criteria for the list.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
function runContextAction(listId) {
    var g_list = GlideList2.get(listId);
    g_list.setGroupBy('');
    g_list.refresh(1);
}
```
GlideList2 - setOrderBy(String orderBy)
Sets the orderBy criteria for the list.

For a single order by field use orderBy field or orderByDescField. For multiple fields, use orderByField1^orderByField2^orderByField3. orderBy specifies ascending order and orderByDesc specifies descending. These prefix strings are optional. If not specified orderBy is assumed.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orderBy</td>
<td>String</td>
<td>Single or multiple order by fields.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

updateOrderBy: function(orderBy){
    var list = GlideList2.get(this.listID);
    if (list)
        list.setOrderBy(orderBy);
};

GlideList2 - setRowsPerPage(Number rows)
Sets the number of rows per page to display.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rows</td>
<td>Number</td>
<td>The number of rows to display</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
link: function(scope) {
    var list = GlideList2.get(scope.listId);
    list.setRowsPerPage(scope.maxRows);
    list.setFilterAndRefresh(scope.tableQuery);
}

**GlideList2 - showHideGroups(Boolean showFlag)***

Shows or hides all the groups within the list and saves the current collapsed/expanded state of the groups as a user preference.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>showFlag</td>
<td>Boolean</td>
<td>If <strong>true</strong>, shows the groups within the list.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

function showHideAllGroups(showFlag) {
    var list = GlideList2.get(listId);
    if (!list)
        return;
    list.showHideGroups(showFlag);
}

**GlideList2 - showHideList(Boolean showFlag)***

Displays or hides the list and saves the current collapsed/expanded state of the list as a user preference.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>showFlag</td>
<td>Boolean</td>
<td>If <strong>true</strong>, displays the list.</td>
</tr>
</tbody>
</table>
### GlideList2.toggleAll

```javascript
GlideList2.toggleAll = function(expandFlag) {
  for (var id in GlideLists2) {
    var list = GlideLists2[id];
    list.showHideList(expandFlag);
  }
}
```

### GlideList2 - sort(String field)

Sorts the list in ascending order and saves the choice.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Specifies the field used to sort the list.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
**GlideList2 - sortDescending(String field, Number amount)**

Sorts the list in descending order and saves the choice.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Specifies the field used to sort the list.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
$timeout(function() {
    if (GlideList.lists) {
        var list = GlideList.get(name);
        if (list) {
            if (sortBy) {
                if (sortDirection == 'ASC')
                    list.sort(sortBy);
                else
                    list.sortDescending(sortBy);
            }
            list.refresh();
        }
    }
})
```

**GlideList2 - toggleList()**

Toggles the display of the list and saves the current collapsed/expanded state of the list as a user preference.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = GlideList2.get(listId);
if (!list)
    return;
list.toggleList();
```

**GlideList2 - toggleListNoPref()**

Toggles the display of the list but does not save the current collapsed/expanded state of the list as a user preference.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = GlideList2.get(listId);
if (!list)
    return;
list.toggleListNoPref();
```

**GlideListV3 (g_list) - Client**

Use GlideListV3 to manipulate lists.

You access the GlideListV3 methods by using the g_list global object. These methods are used in UI context menus and UI actions. The g_list object is not available for related lists on the form link UI action.

**Note:**

This API is no longer supported. Consider using the GlideList2() API instead.
**GlideListV3 - addFilter(String filter)**  
Adds a single term to the list query filter.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filter</td>
<td>String</td>
<td>Query string condition to add.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideListV3 - get(String listId)**  
Returns the GlideList object for specified list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>listId</td>
<td>String</td>
<td>The list name.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The GlideList object for the specified list, or null if not found.</td>
</tr>
</tbody>
</table>

**GlideListV3 - get(Object DomElement)**  
Returns the GlideList object for the specified DOM element.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DomElement</td>
<td>Object</td>
<td>The DOM element ID for which you want the GlideList object.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The GlideList object for the specified DOM element. Returns null if the DOM element is not found.</td>
</tr>
</tbody>
</table>

GlideListV3 - getChecked()

Returns a comma-separated list of sys_ids for checked items in the list. Does not return items that are not allowed to be executed.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Comma-separated list of the sys_ids for checked items in the list. Does not return items that are not allowed to be executed.</td>
</tr>
</tbody>
</table>

GlideListV3 - getFixedQuery()

Returns the sysparm_fixed query.

The fixed query is the part of the query that cannot be removed from the breadcrumb (i.e., it is fixed for the user). It is specified by including a sysparm_fixed_query parameter for the application module.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The fixed query string for the list.</td>
</tr>
</tbody>
</table>
GlideListV3 - getFormTarget()
Returns the form's target attribute.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The form's target attribute.</td>
</tr>
</tbody>
</table>

GlideListV3 - getGroupBy()
Returns the field or comma-separated list of fields that are used to group the list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The field or comma-separated list of fields used to group the list.</td>
</tr>
</tbody>
</table>

GlideListV3 - getListName()
Returns the name of the list, which is usually the table name.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>String</td>
<td>The list name.</td>
<td></td>
</tr>
</tbody>
</table>

GlideListV3 - getOrderBy()

Returns the first field used to order the list.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

GlideListV3 - getParentTable()

Returns the name of the parent table (the table associated with the form).

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

GlideListV3 - getQuery(Object options)

Returns the encoded query string for the list.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Object</td>
<td>The options can be one or more of the following.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• orderby - include ORDERBY in the query</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• groupby - include GROUPBY in the query</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• fixed - include sysparm_fixed_query in the query</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• all - include all the options in the query</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Encoded query string for the list.</td>
</tr>
</tbody>
</table>

**GlideListV3 - getReferringUrl()**

Returns the referring URL.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Returns the parent form's URL, or '*' if there is no parent form.</td>
</tr>
</tbody>
</table>

**GlideListV3 - getRelated()**

Returns the related list field that associates the related list to the parent form.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Field that connects the list to the parent form.</td>
</tr>
</tbody>
</table>

**GlideListV3 - getRelatedListType()**

Returns the related list type.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The relationship table type.</td>
</tr>
</tbody>
</table>

**GlideListV3 - getRelationshipId()**

Returns the relationship record id, if this is type REL related list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The sys_id of the relationship record.</td>
</tr>
</tbody>
</table>

**GlideListV3 - getRowCount()**

Returns the number of rows returned by the query.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of rows returned by the query.</td>
</tr>
</tbody>
</table>

**GlideListV3 - getRowsPerPage()**

Returns the number of rows to be displayed on a page.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of rows to be displayed on a page.</td>
</tr>
</tbody>
</table>

**GlideListV3 - getTableName()**

Returns the table name of the list.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The list's table name.</td>
</tr>
</tbody>
</table>
GlideListV3 - getTitle()

Returns the list title.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The list title.</td>
</tr>
</tbody>
</table>

GlideListV3 - getView()

Returns the view used to display the list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The name of the view</td>
</tr>
</tbody>
</table>

GlideListV3 - isUserList()

Returns true if the list has been personalized by the user.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>--------</td>
<td>------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Boolean</td>
<td>True if the list layout has changed.</td>
<td></td>
</tr>
</tbody>
</table>

**GlideListV3 - refresh(Number firstRow, Object additionalParams)**
Refreshes the list. The orderBy part of the list filter is ignored so that the list's natural ordering is used.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>firstRow</td>
<td>Number</td>
<td>(Optional) The first row to display in the list. If not specified, the list's current first row is used.</td>
</tr>
<tr>
<td>additionalParams</td>
<td>Object</td>
<td>(Optional) Name- value pairs that are submitted with the list refresh request.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideListV3 - refreshWithOrderBy(Number firstRow, Object additionalParams)**
Refreshes the list using the orderBy fields.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>firstRow</td>
<td>Number</td>
<td>(Optional) The first row to display in the list. If not specified, the list's current first row is used.</td>
</tr>
<tr>
<td>additionalParams</td>
<td>Object</td>
<td>(Optional) Name- value pairs that are submitted with the list refresh request.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideListV3 - setFilter(String filter, Boolean saveOrderBy, Boolean saveGroupBy)

Sets the encoded query string for the list ignoring the orderBy and groupBy parts of the query string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filter</td>
<td>String</td>
<td>An encoded query string.</td>
</tr>
<tr>
<td>saveOrderBy</td>
<td>Boolean</td>
<td>The default is false. When true uses the orderBy part of the query.</td>
</tr>
<tr>
<td>saveGroupBy</td>
<td>Boolean</td>
<td>The default is false. When true uses the groupBy part of the query.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideListV3 - setFilterAndRefresh( String filter)

Sets the encoded query string for the list, and then refreshes the list using the new filter.

This preserves the groupby and orderby parameters.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filter</td>
<td>String</td>
<td>Encoded query string.</td>
</tr>
</tbody>
</table>
GlideListV3 - setFirstRow(Number firstRow)

Sets the first row to be displayed when the list is refreshed.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>firstRow</td>
<td>Number</td>
<td>The row number in the list.</td>
</tr>
</tbody>
</table>

GlideListV3 - setFormTarget(String target)

Specifies where to display the response from the form.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>target</td>
<td>String</td>
<td>The form.target attribute value to use.</td>
</tr>
</tbody>
</table>

GlideListV3 - setGroupBy(String groupBy)

Sets the `groupBy` criteria for the list, for a single field or multiple fields.
For a single field, use field or groupByField. The groupBy prefix is optional. For multiple fields use field1^field2^field3 or groupByField1^groupByField2^groupByField3.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>groupBy</td>
<td>The group by criteria for the list.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideListV3 - setOrderBy(String orderBy)**

Sets the orderBy criteria for the list.

For a single order by field use orderBy field or orderByDescField. For multiple fields, use orderByField1^orderByField2^orderByField3. orderBy specifies ascending order and orderByDesc specifies descending. These prefix strings are optional. If not specified orderBy is assumed.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orderBy</td>
<td>String</td>
<td>Single or multiple order by fields.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideListV3 - setReferringUrl(String url)**

Sets the parent form referring url.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>The parent form’s URL</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

#### GlideListV3 - setRowsPerPage(Number numRows)

Set the number of rows to display on a page.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>numRows</td>
<td>Number</td>
<td>The number of rows to display on a page.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

#### GlideListV3 - showHideGroups(Boolean showFlag)

Displays or hides all of the groups within the list and saves the current collapsed/expanded state of the groups as a user preference.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>showFlag</td>
<td>Boolean</td>
<td>When true, displays the groups within the list.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
**GlideListV3 - showHideList(Boolean showFlag)**
Displays or hides the list and saves the current collapsed/expanded state of the list as a user preference.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>showFlag</td>
<td>Boolean</td>
<td>When true, displays the list.</td>
</tr>
</tbody>
</table>

**Parameters**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideListV3 - sort(String field)**
Sort the list in ascending order.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>The field to be used to sort the list.</td>
</tr>
</tbody>
</table>

**Parameters**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideListV3 - sortDescending(String field)**
Sorts the list in descending order.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>The field used to sort the list.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
GlideListV3 - toggleList()
Toggles the list display between collapsed and expanded, and saves the state as a user preference.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

GlideListV3 - toggleListNoPref()
Toggles the list display between collapsed and expanded, but does not save the state as a user preference.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

GlideListProperties - Global
Create a list and set list properties. For example, define whether a list has a filter, breadcrumbs, and search.
Use GlideListProperties in global server-side scripts. To use this class, instantiate a GlideListProperties object using the constructor.

For an example of this class in the base system, configure a list and select All. The tabbed list of options uses the personalize_all UI page and personalize_all_list UI macro to set list properties such as title, context menu, and breadcrumbs.

GlideListProperties - GlideListProperties()

Instantiates a GlideListProperties object.

```
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

var list = new GlideListProperties();
```

GlideListProperties - getListID()

Returns the unique ID for a list.

```
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

var list = new GlideListProperties();
var getID = list.getListID();
gs.print(getID);

Output: 3519f77ad95f5700964f387107a8a394
```

GlideListProperties - getName()

Returns the name of the list.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of the list.</td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var setName = list.setListName("my custom list");
var getName = list.getListName();
gs.print(getName);
```

Output: my custom list

**GlideListProperties - getTitle()**

Get the title of a list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The title of the list.</td>
</tr>
</tbody>
</table>

Optional example explanation

```javascript
var list = new GlideListProperties();
var title = list.setTitle("My title");
var getTitle = list.getTitle();
gs.print(getTitle);
```

Output: My title
** GlideListProperties - hasActions() **

Returns whether or not the **Actions on select rows** option is enabled for a list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns <strong>true</strong> if the actions option is enabled for a list.</td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var actions = list.setHasActions(true);
var hasActions = list.hasActions();
gs.print(hasActions);
```

Output: true

** GlideListProperties - hasBottomNav() **

Returns whether or not a list has navigation at the bottom.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>If returns <strong>true</strong> the list has bottom navigation.</td>
</tr>
</tbody>
</table>

```javascript
var lp = new GlideListProperties();
var Nav = lp.setHasBottomNav(true);
var hasNav = lp.hasBottomNav();
gs.print(hasNav);
```

Output: true

**GlideListProperties - hasBottomVCR()**

Returns whether or not the page navigation controls appear in the footer of a list.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>If true the page navigation controls appear in the footer of a list</td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var vcr = list.setHasBottomVCR(true);
var hasVCR = list.hasBottomVCR();
gs.print(hasVCR);
```

Output: true

**GlideListProperties - hasFilter()**

Returns whether or not a list has a filter.

The filter property is a parent of the breadcrumbs property. If the filter property is listed as false and the breadcrumb is listed as true, `hasFilter()` still returns true because the child property is marked as true.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>If true a filter icon appears with the list, or the breadcrumb property is listed as true. If false both the filter property and the breadcrumb property are marked as false.</td>
</tr>
</tbody>
</table>
var list = new GlideListProperties();
var filter = list.setHasFilter(true);
var breadcrumbs = list.setHasBreadcrumbs(true);
var hasFilter = list.hasFilter();
gs.print(hasFilter);

Output: true

GlideListProperties - hasHeader()
Returns whether or not a list has a header.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns <strong>true</strong> if a list has a header.</td>
</tr>
</tbody>
</table>

var list = new GlideListProperties();
var header = list.setHasHeader(true);
var hasHeader = list.hasHeader();
gs.print(hasHeader);

Output: true

GlideListProperties - hasHeaderContextMenu()
Returns whether or not a header context menu is enabled for a list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Returns</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>Boolean</td>
<td>If true a context menu displays next to each column header in a list.</td>
</tr>
</tbody>
</table>

```
var list = new GlideListProperties();
var header = list.setHeaderContextMenu(true);
var hasHeader = list.getHeaderContextMenu();
gs.print(hasHeader);
```

Output: true

**GlideListProperties - hasListMechanic()**

Returns whether list personalization is enabled for a list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Boolean</td>
<td>If true the list mechanic is enabled for a list and the Personalize List</td>
</tr>
<tr>
<td></td>
<td></td>
<td>icon appears on the page.</td>
</tr>
</tbody>
</table>

```
var list = new GlideListProperties();
var mechanic = list.setHasListMechanic(true);
var hasMechanic = list.hasListMechanic();
gs.print(hasMechanic);
```

Output: true

**GlideListProperties - hasPopup()**

Returns whether or not a list can have popup windows.
GlideListProperties - hasPopup()

Returns true if the list allows popups.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if the list allows popups.</td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var popup = list.setHasPopup(true);
var hasPopup = list.hasPopup();
gs.print(hasPopup);
```

Output: true

GlideListProperties - hasRowContextMenu()

Returns whether or not rows in a list have a context menu.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>If true a list row can have a context menu.</td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var contextMenu = list.setHasRowContextMenu(true);
var hasContextMenu = list.hasRowContextMenu();
gs.print(hasContextMenu);
```

Output: true

GlideListProperties - hasSearch()

Returns whether or not the search bar is enabled for a list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>If true a list row can have a context menu.</td>
</tr>
</tbody>
</table>
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>If true the search bar appears in the header of a list.</td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var search = list.setHasSearch(true);
var hasSearch = list.hasSearch();
gs.print(hasSearch);
```

Output: true

**GlideListProperties - hasTitle()**

Returns whether or not the list title appears in the list header.

The title context menu is a child property of title. If `setHasTitleContextMenu` is set to true, `hasTitle` also returns true, even if `setHasTitle` is set to false.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>If true the list title appears in the list header.</td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var title = list.setHasTitle(true);
var contextMenu = list.setHasTitleContextMenu(true); 
var hasTitle = list.hasTitle();
gs.print(hasTitle);
```

Output: true
GlideListProperties - hasTitleContextMenu()

Returns whether a context menu appears in a list header.

The title context menu is a child property of title. If `setHasTitleContextMenu` is set to true, `hasTitle` also returns true, even if `setHasTitle` is set to false.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Boolean</td>
</tr>
</tbody>
</table>

Optional example explanation

```javascript
var list = new GlideListProperties();
var contextMenu = list.setHasTitleContextMenu(true);
var hasContextMenu = list.hasTitleContextMenu();
gs.print(hasContextMenu);
```

Output: true

GlideListProperties - hasTopVCR()

Returns whether or not the page navigation controls appear in the header of a list.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Boolean</td>
</tr>
</tbody>
</table>
var list = new GlideListProperties();
var vcr = list.setHasTopVCR(true);
var hasVCR = list.hasTopVCR();
gs.print(hasVCR);

Output: true

**GlideListProperties - isOmitFilter()**

Returns whether or not the omit filter option has been selected.

The ListControl omit flags take precedence in that if they are set, they negate the setting of their corresponding flag. For example, if the show filter flag has been set to true, but the ListControl omit filter is true, then checking hasFilter returns false.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Boolean</td>
</tr>
</tbody>
</table>

var lp = new GlideListProperties();
var omitFilter = lp.isOmitFilter();
gs.print(omitFilter);

Output: false

**GlideListProperties - isSaveFilterHidden()**

Returns whether the Save Filter button is hidden in the condition builder.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>If <strong>true</strong> the Save Filter button is hidden in the condition builder.</td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var SaveFilter = list.setSaveFilterHidden(true);
var hasSaveFilter = list.isSaveFilterHidden();
gs.print(hasSaveFilter);
```

Output: true

**GlideListProperties - isShowLinks()**

Returns whether or not a list shows links.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var links = list.setShowLinks(true);
var hasLinks = list.isShowLinks();
gs.print(hasLinks);
```

Output: true

**GlideListProperties - isToggleHeader()**

Returns whether or not toggling the header columns is available for a list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>If <strong>true</strong> users can show or hide the column headers for a table.</td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var toggle = list.setToggleHeader(true);
var hasToggle = list.isToggleHeader();
gs.print(hasToggle);
```

Output: true

### GlideListProperties - setCanChangeView(Boolean onOff)

Determine whether the user can change the view for the list.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If <strong>false</strong> users cannot change the list view. By default, changing views is enabled.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var changeView = list.setCanChangeView(true);
```

### GlideListProperties - setCanGroup(Boolean onOff)

Determine whether users can group items in a list.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If <strong>false</strong>, the group by option does not appear in the column context menu. By default the group by option appears in the list context menu.</td>
</tr>
</tbody>
</table>

### GlideListProperties - setCanGroup(Boolean onOff)

Determine whether the sort option is available in a list.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If false, the sort option does not appear in column list context menu, and users cannot click the column title to change the order of the list.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var canGroup = list.setCanGroup(true);
```

### GlideListProperties - setCanSort(Boolean onOff)

Determine whether the sort option is available in a list.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If false, the sort option does not appear in column list context menu, and users cannot click the column title to change the order of the list.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var canSort = list.setCanSort(true);
```

### GlideListProperties - setContextMenus(Boolean onOff)

Displays or hides all of the available context menus for a list.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If set to true displays the title context menu, header context menu, and list context menu for a list.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var contextMenus = list.setContextMenus(true);
```
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var context = list.setContextMenus(true);
```

**GlideListProperties - setHasActions(Boolean)**

Determine whether the Actions on select rows options display at the bottom of a list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If true displays action options for a list.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var actions = list.setHasActions(true);
```

**GlideListProperties - setHasBottomNav(Boolean onOff)**

Determine whether the navigation actions at the bottom of a list are hidden or not.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>When true adds navigation to the bottom of a list.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var lp = new GlideListProperties();
var bottom = lp.setHasBottomNav(true);
```

**GlideListProperties - setHasBreadcrumbs(Boolean onOff)**

Determine whether or not breadcrumbs appear at the top of a list.

Breadcrumbs are a child of filters. To hide breadcrumbs completely, you need to also set the filter to false.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If true, breadcrumbs appear at the top of a list.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var breadcrumbs = list.setHasBreadcrumbs(true);
```

**GlideListProperties - setHasBottomVCR(Boolean onOff)**

Determine whether the first page, last page, next page, and previous page buttons appear at the bottom of the list.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If true, the first page, last page, next page, and previous page buttons appear at the bottom of the list.</td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>void</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```java
var list = new GlideListProperties();
var bottomVCR = list.setHasBottomVCR(true);
```

### GlideListProperties - setHasFilter(Boolean onOff)
Determine whether or not the filter displays as part of a list.

The filter is a parent of breadcrumbs. To remove the filter, you need to set both the filter and the breadcrumbs to false.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>onOff</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

```java
var list = new GlideListProperties();
var filter = list.setHasFilter(true);
```

### GlideListProperties - setHasHeader(Boolean onOff)
Determine whether or not a list displays a header.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>onOff</td>
</tr>
</tbody>
</table>
### GlideListProperties - setHasHeaderContextMenu(Boolean onOff)

Determine whether or not the context menu appears next to each column in a list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If true the context menu appears next to each column in a list.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var header = list.setHasHeader(true);
```

### GlideListProperties - setHasListMechanic(Boolean onOff)

Determine whether or not a list has the option for personalization.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If true the list mechanic is enabled and the Personalize List icon appears on the page.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var actions = list.setHasHeaderContextMenu(true);
```
GlideListProperties - setHasPopup(Boolean onOff)

Determine whether the list has a popup or modal window.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If true the list can have popup windows.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideListProperties - setHasRowContextMenu(Boolean onOff)

Determines whether or not list rows have a context menu.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>When true list rows can have a context menu.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var list = new GlideListProperties();
var contextMenu = list.setHasRowContextMenu(true);

**GlideListProperties - setHasSearch(Boolean onOff)**
Determine whether search appears for a list.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If <strong>true</strong> the search bar appears in the list header.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var list = new GlideListProperties();
var search = list.setHasSearch(true);

**GlideListProperties - setHasTitle(Boolean onOff)**
Determine whether the list title appears in the header.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If <strong>true</strong> the title of the list appears in the list header.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var list = new GlideListProperties();
var title = list.setHasTitle(true);

**GlideListProperties - setHasTitleContextMenu(Boolean onOff)**
Determine whether or not a list has a context menu in the header.
### GlideListProperties - setHasTitleContextMenu(Boolean onOff)

Determine whether or not a list has the context menu appears next to the list title in the header.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If true the context menu appears next to the list title in the header</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var contextMenu = list.setHasTitleContextMenu(true);
```

### GlideListProperties - setHasTopVCR(Boolean onOff)

Determine whether or not a list has the page navigation controls in the list header.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If true the page navigation controls appear in the header of a list</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var vcr = list.setHasTopVCR(true);
```

### GlideListProperties - setHideRows(Boolean onOff)

Determine whether rows are visible in a list.
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If true all of the rows are hidden for a list.</td>
</tr>
</tbody>
</table>

**GlideListProperties - setSaveFilterHidden(Boolean onOff)**

Determine whether the Save Filter button appears in the condition builder.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If true the Save Filter button is hidden.</td>
</tr>
</tbody>
</table>

**GlideListProperties - setListID(String ID)**

Set the unique ID for a list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unique ID</td>
<td>String</td>
<td>The unique ID for the list.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var setID = list.setListID("a9dd1483d99f5700964f387107a8a3ec");
var getID = list.getListID();
gs.print(getID);
```

Output: a9dd1483d99f5700964f387107a8a3ec

**GlideListProperties - setListName(String name)**

Defines a name for the list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the list.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var name = list.setListName("my custom list");
```

**GlideListProperties - setShowLinks(Boolean onOff)**

Whether or not a list includes links.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If true list includes related links.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var links = list.setShowLinks(true);
```

GlideListProperties - setTitle(String title)

Defines the list title.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>String</td>
<td>Title for the list.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var title = list.setTitle("My title");
```

GlideListProperties - setToggleHeader(Boolean onOff)

Determine whether users can show or hide column headers for a table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If <strong>true</strong> an icon appears in the header that allows users to show or hide the column headers.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
```javascript
var list = new GlideListProperties();
var toggle = list.setToggleHeader(true);

GlideListProperties - setVCR(Boolean onOff)
Determine whether the first page, last page, next page, and previous page buttons appear at the top and bottom of the list.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>onOff</td>
<td>Boolean</td>
<td>If false, the list does not have any of the page navigation buttons for a list.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var list = new GlideListProperties();
var VCR = list.setVCR(true);

GlideLocale - Scoped
GlideLocale provides information about display information for the local instance.
There is no constructor for a GlideLocale object. Use the get() method to get a GlideLocale object.

Scoped GlideLocale - get()
Returns the GlideLocale object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## GlideLocale

### GlideLocale

**Description**

The GlideLocale object.

```javascript
var locale = GlideLocale.get();
```

### Scoped GlideLocale - getDecimalSeparator()

**Returns**

**Type**

String

**Description**

The decimal separator.

```javascript
var locale = GlideLocale.get();
var decimalSeparator = locale.getDecimalSeparator();
gs.info( "The decimal separator is " + decimalSeparator);
```

**Output:**

The decimal separator is .

### Scoped GlideLocale - getGroupingSeparator()

**Returns**

**Type**

String

**Description**

The grouping separator.

```javascript
var locale = GlideLocale.get();
var groupingSeparator = locale.getGroupingSeparator();
gs.info( "The grouping separator is " + groupingSeparator);
```
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The grouping separator.</td>
</tr>
</tbody>
</table>

```javascript
var locale = GlideLocale.get();
var groupingSeparator = locale.getGroupingSeparator();
gs.info( "The grouping separator is " + groupingSeparator);
```

Output:

```
The grouping separator is ,
```

**GlideMenu (g_menu and g_item) - Client**

GlideMenu methods are used in UI Context Menus, in the onShow scripts to customize UI Context Menu items.

There is no constructor for the GlideMenu class. Access GlideMenu methods using the g_menu global object.

- **g_menu** is the UI Context Menu that is about to be shown. The onShow script can make changes to the appearance of the menu before it is displayed using these methods.

- **g_item** is the current UI Context Menu item that is about to be shown. It is used in several of the g_menu methods to specify an item.

**GlideMenu - clearImage(GlideMenuItem item)**

Clears the image for an item.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>item</td>
<td>GlideMenuItem</td>
<td>Specifies the item to have its image removed from display.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
// Clears the image for an item
...
g_menu.clearImage(g_item);
```
GlideMenu - clearSelected()
Clears any selection images from items in the menu.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideMenu - getItem(String itemID)
Returns a menu item by item ID.

It can be necessary to find an item in a menu so that it can be changed before being displayed. Each menu item may be assigned a unique ID when the menu item is created (either from a UI Context Menu entry or from the addAction() method in the Dynamic Script Action).

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>itemID</td>
<td>String</td>
<td>Specifies the item to be returned.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideMenuItem</td>
<td>The menu item</td>
</tr>
</tbody>
</table>

GlideMenu - setDisabled(GlideMenuItem item)
Disables a menu item so that it cannot be selected. The disabled menu item is displayed in a lighter color (grayed out) to indicate it is disabled.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>item</td>
<td>GlideMenuItem</td>
<td>The item to be disabled.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
g_menu.setDisabled(g_item);
```

**GlideMenu - setEnabled(GlideMenuItem item)**

Enables the specified menu item.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>item</td>
<td>GlideMenuItem</td>
<td>The item to be enabled.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
g_menu.setEnabled(g_item);
```

**GlideMenu - setHidden(GlideMenuItem item)**

Hides the specified menu item.

When hiding menu items, the separator bars are not adjusted, so it is possible to end up with the menu showing two separators in a row.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>item</td>
<td>GlideMenuItem</td>
<td>The item to be hidden.</td>
</tr>
</tbody>
</table>
GlideMenu - setHidden(GlideMenuItem item)
Sets an image for an item.

Parameters
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>item</td>
<td>GlideMenuItem</td>
<td>the item to have the image displayed.</td>
</tr>
</tbody>
</table>

GlideMenu - setImage(GlideMenuItem item, String imgSrc)
Sets the display label for a menu item. The label may contain HTML.

Parameters
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>item</td>
<td>GlideMenuItem</td>
<td>the item to be labeled.</td>
</tr>
<tr>
<td>label</td>
<td>String</td>
<td>the label to be displayed. The string may contain HTML.</td>
</tr>
</tbody>
</table>

Returns
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
g_menu.setLabel(g_item, "This is a new label");

**GlideMenu - setVisible(GlideMenuItem item)**

Displays the specified item.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>item</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

g_menu.setVisible(g_item);

**GlideModalFormV3 - Client**

Displays a form in a GlideModal.

General usage of the GlideModalForm class involves creating the object, setting any preferences, and then rendering the GlideModalForm.

```javascript
var d = new GlideModalForm('dialog title', 'table_name_or_form_name', [callback on completion of submit])
    d.setPreference('name', 'value');
    d.render();
```

Specify the query parameters that are passed to the form using `setPreference()`. Any name/value pair that you specify with `setPreference()` is sent along with the form POST request to display the form.

The GlideFormModal is set to fill the height of the document window.

**GlideModalFormV3 - addParm(String name, String value)**

Sets the specified form field to the specified value.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Form field name. If the specified name is not a field in the associated modal form, it is ignored.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Value to set the specified form field to.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to call `addParm()` to set the value of the sys_id field the modal form.

```javascript
function openDevice(deviceSysID, deviceName) {
  var uName = gel('hidden_user_name').value + "'s ";
  deviceName = new String(deviceName).escapeHTML();
  var gp = new GlideModalForm(uName + deviceName, "cmn_notif_device", refreshNotifPage);
  gp.addParm('sys_id', deviceSysID);
  gp.render();
}
```

**GlideModalFormV3 - GlideModalForm(String title, String tableName, Function onCompletionCallback, Boolean readOnly)**

Creates an instance of the GlideModalForm class.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>String</td>
<td>Modal form title.</td>
</tr>
<tr>
<td>tableName</td>
<td>String</td>
<td>Table being shown.</td>
</tr>
<tr>
<td>onCompletionCallback</td>
<td>Function</td>
<td>Function to call after the form has been submitted and processed on the server.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The callback function has the form <code>callbackFunction(String action_verb, String sys_id, String table, String displayValue) where:</code></td>
</tr>
</tbody>
</table>
Parameters (continued)
Name

Type

Description

• action_verb: Name of the UI action
executed. Examples are sysverb_insert
(Submit button), sysverb_cancel,
sysverb_save (Save button).
• sys_id: Sys_id of the affected record.
• table: Name of the table containing the
record.
• displayValue: Value that appears on the
form.
readOnly

Boolean Optional. Flag that indicates whether the
modal form should be set to read only.
Valid values:
• true: Set form to read only.
• false: Set for to read/write.
Default: false

This example shows how to instantiate a GlideModalForm object.
function openDevice(deviceSysID, deviceName) {
var uName = gel('hidden_user_name').value + "'s ";
deviceName = new String(deviceName).escapeHTML();
var gp = new GlideModalForm(uName + deviceName, "cmn_notif_device", refreshNotifPage);
gp.addParm('sys_id', deviceSysID);
gp.render();
}

GlideModalFormV3 - render()
Shows the modal form.
Parameters
Name

Type

Description

None

This example shows how to call `render()` to display the modal.

```javascript
function openDevice(deviceSysID, deviceName) {
    var uName = gel('hidden_user_name').value + "'s ";
    deviceName = new String(deviceName).escapeHTML();
    var gp = new GlideModalForm(uName + deviceName, "cmn_notif_device", refreshNotifPage);
    gp.addParm('sys_id', deviceSysID);
    gp.render();
}
```

**GlideModalFormV3 - setCompletionCallback(Function callbackFunction)**

Sets the function to be called when the form has been successfully submitted and processed by the server.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callbackFunction</td>
<td>Function</td>
<td>Callback function to call when the form has been successfully processed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The callback function has the form</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>callbackFunction(String action_verb, String sys_id, String table, String displayValue)</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td>where:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>action_verb</code>: action_name from a sys_ui_action record</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>sys_id</code>: Sys_id of the affected record</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>table</code>: Name of the table containing the record</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <code>displayValue</code>: Value that appears on the form</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
This example shows how to set the onload callback function of the associated modal.

```javascript
function handleCreateOrEdit(targetFieldName, sourceFieldName, adapterRuleId, transformerSysId) {
    dialog = new GlideModalForm('Edit Adapter Rule', 'sys_adapter_rule');
    dialog.setSysID(adapterRuleId); // Pass in sys_id to edit existing record
    dialog.addParm('sysparm_form_only', 'true'); // Add or remove related lists
    dialog.setOnloadCallback(hideModalForm);
    dialog.setCompletionCallback(handleAdapterCreatedOrUpdated);
    dialog.render(); // Open the dialog
}
function handleAdapterCreatedOrUpdated(action_verb, sys_id, table, displayValue) {
    var draftRecordTransformer = g_form.getValue('draft_record_transformer');
    if(draftRecordTransformer == null || draftRecordTransformer.length == 0) {
        // sync Sticky Replications if it is enabled.
        var ajax = new GlideAjax('ReplicationPoolUtil');
        ajax.addParam('sysparm_name', 'syncStickyReplicationSet');
        ajax.addParam('sysparm_entry_set', g_form.getValue('entry_set'));
        ajax.getXMLWait();
    }
}
```

**GlideModalFormV3 - setOnloadCallback(Function callbackFunction)**

Sets the function to be called after the form has been loaded.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>callbackFunction</td>
<td>Function</td>
<td>Function to call after the form has been loaded. The callback function has the form callbackFunction(GlideModalForm obj)</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to set the on load callback function of the associated modal.
function handleCreateOrEdit(targetFieldName, sourceFieldName, adapterRuleId, transformerSysId) {
    dialog = new GlideModalForm('Edit Adapter Rule', "sys_adapter_rule");
    dialog.setSysID(adapterRuleId); //Pass in sys_id to edit existing record
    dialog.addParm('sysparm_form_only', 'true'); //Add or remove related lists
    dialog.setOnloadCallback(hideModalForm);
    dialog.setCompletionCallback(handleAdapterCreatedOrUpdated);
    dialog.render(); //Open the dialog
}

GlideModalFormV3 - setSysID(String sys_id)
Sets the object's sys_id preference.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>String</td>
<td>The id preference. One of the query parameters passed to the form.</td>
</tr>
</tbody>
</table>

This example shows how to use the `setSysID()` method to initialize the value of the `sys_id`.

function(startDate, endDate) {
    var dialog = new GlideModalForm("Add Schedule Item", "cmn_schedule_span");
    dialog.setSysID("-1");
    dialog.addParm("sysparm_collection", "cmn_schedule");
    dialog.addParm("sysparm_collectionID", this.sysId);
    dialog.addParm("sysparm_collection_key", "schedule");

    var q = "schedule=" + this.sysId + "^start_date_time=" + startDate.serializeInUserFormat() + "^end_date_time=" + endDate.serializeInUserFormat() + "^";

    if (startDate.isAllDay(endDate))
        q += "^all_day=true";
dialog.addParm("sysparm_query", q);
dialog.render();
}

GlideModalV3 - Client

Provides methods for displaying a content overlay.

This is a fully-featured replacement for GlideWindow and GlideDialogWindow.

Example overlay

GlideModalV3 - get(String id)

Get a GlideModal object by ID.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>The element id of the GlideModal object.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideModal</td>
<td>The object.</td>
</tr>
</tbody>
</table>

GlideModalV3 - getPreference(String name)

Returns the value of the specified preference (property).

Invoking actions that create the modal typically also create the necessary preferences for the modal using the GlideModalV3 - setPreference(String name, String value) method. The UI page client script then consumes these preferences using this method.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the preference value to retrieve. This value must have previously been set on the modal using the GlideModalV3 - setPreference(String name, String value) method.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Specified preference's value.</td>
</tr>
</tbody>
</table>

This example shows a simple case of setting a preference and then retrieving that preference from a specified modal.

```javascript
var gm = new GlideModal('UI_dialog_name');
//Sets the dialog title
gm.setTitle('Show title');

//sets the value of the preference table
gm.setPreference('table', 'incident');

//gets the value of the preference table
var title = gm.getPreference('table');
```

**GlideModalV3 - GlideModal(String id, Boolean readOnly, Number width)**

Creates an instance of the GlideModalV3 class.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>The UI page to load into the modal.</td>
</tr>
<tr>
<td>readOnly</td>
<td>Boolean</td>
<td>When true, hides the close button.</td>
</tr>
<tr>
<td>width</td>
<td>Number</td>
<td>The width in pixels.</td>
</tr>
</tbody>
</table>

**GlideModalV3 - render()**

Renders the UI page in the modal.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gm = new GlideModal("UI_dialog_name");

//Sets the dialog title
gm.setTitle('Show title');
gm.setWidth(550);

//Opens the dialog
gm.render();
```

#### GlideModalV3 - renderWithContent(String html)
Display a modal with the specified HTML content.

The `renderWithContent()` method replaces the `render()` method, and does not request a UI page to render.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>html</td>
<td>String</td>
<td>The HTML content to be shown in the modal.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

#### GlideModalV3 - renderWithContent(Object html)
Display a modal with the specified HTML content.
The `renderWithContent()` method replaces the `render()` method, and does not request a UI page to render.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>html</td>
<td>Object</td>
<td>The HTML content to be shown in the modal.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideModalV3 - setPreference(String name, String value)**

Sets the specified field on the current form to the specified value.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the form field to update. If this field does not exist on the current form, the request is ignored.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Value to store in the specified form field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gm = new GlideModal('UI_dialog_name');
//Sets the dialog title
gm.setTitle('Show title');
gm.setPreference('table', 'task');
gm.setPreference('name', 'value');

//Opens the dialog
gm.render();
```
GlideModalV3 - setPreferenceAndReload(Array properties)
Set the properties and reload the modal.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>properties</td>
<td>Array</td>
<td>An array of name-value pairs to be set.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideModalV3 - setTitle(String title)
Sets the title of the modal.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>String</td>
<td>The title to be displayed</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gm = new GlideModal('UI_dialog_name');

//Sets the dialog title
gm.setTitle('Show title');
gm.setPreference('name', 'value');

//Opens the dialog
gm.render();
```

GlideModalV3 - setWidth(Number width)
Set the width in pixels.
The modal is boxed into predefined system sizes.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>width</td>
<td>Number</td>
<td>The number of pixels.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gm = new GlideModal('UI_dialog_name');
//Sets the dialog title
gm.setTitle('Show title');
gm.setPreference('name', 'value');
gm.setWidth(550);
//Opens the dialog
gm.render();
```

**GlideModalV3 - switchView(String newView)**

Change the view and reload the modal.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>newView</td>
<td>String</td>
<td>The view to use.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideNavigationV3 - Client**

Provides methods to control and refresh the navigator and main frame.
The GlideNavigation methods are accessed using the g_navigation global object.

**GlideNavigationV3 - open(String url, String target)**

Redirects to a new URL.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>The URL to load. It can be any URL supported by the browser.</td>
</tr>
<tr>
<td>target</td>
<td>String</td>
<td>Optional. The frame in which to load the content specified by the URL.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: Current frame</td>
</tr>
</tbody>
</table>

This example shows how to open the list of active incidents within an instance and display the content in the current frame.

```javascript
g_navigation.open('incident_list.do?sysparm_query=active=true');
```

**GlideNavigationV3 - openPopup(String url, String name, String features, Boolean noStack)**

Opens the specified URL in a popup window.

The **features** parameter is part of the DOM specification and is passed through. For more information on the available feature list, refer to the Mozilla Developer Network.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>URL to open.</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>Window name.</td>
</tr>
<tr>
<td>features</td>
<td>String</td>
<td>Comma separated list of features for the popup window.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| noStack | Boolean   | Flag that indicates whether to append `sysparm_stack=no` to the URL. This parameter helps prevent unexpected behavior when using the form back button. Valid values:  
  • true: Append `sysparm_stack=no` to the URL.  
  • false: Do not append `sysparm_stack=no` to the URL. |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Window</td>
<td>Instance of the new window.</td>
</tr>
</tbody>
</table>

This example shows how to open the list of active incidents within a popup window called "Active Incidents", and enable the resizable, scrollbars, and status features on the window.

```javascript
const openPopup = (url, title, attributes, closeOnNavExit) => {
  return g_navigation.openPopup(url, title, attributes, closeOnNavExit);
}

g_navigation.openPopup('incident_list.do?sysparm_query=active=true', 'Active Incidents', 'resizable,scrollbars,status', true);
```

**GlideNavigationV3 - openRecord(String tableName, String sys_id)**

Redirects to a record. The record displays in the navigator frame.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table containing the record to display.</td>
</tr>
<tr>
<td>sys_id</td>
<td>String</td>
<td>Sys_id of the record to display.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to open a specified incident record in the navigator frame.
GlideNavigationV3 - refreshNavigator()

Refreshes content in the navigator frame.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to refresh the content in the navigator frame.

```javascript
g_navigation.refreshNavigator();
```

GlideNavigationV3 - reloadWindow()

Reloads the current frame.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to refresh the content in the current frame.

```javascript
g_navigation.reloadWindow();
```

GlideNotificationV3 - Client

You can show messages over the page content.
The GlideNotification method is accessed using the `g_notification` global object. List V3 must be activated for the `g_notification` object to be available.

**GlideNotificationV3 - show(String type, String message)**
Displays the specified string over the page content as the specified type of message.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>The type of message - error, warning, or info.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
// Displays an info message at the top of the screen
nowapi.g_notification.show("info", "The record has been updated");

// Displays an error message at the top of the screen
nowapi.g_notification.show("error", "You need to provide notes!");
```

**GlideOAuthClient - Scoped, Global**
Use these methods for requesting and revoking OAuth refresh and access tokens.

This API can be used in global and scoped scripts. In scoped scripts use the `sn_auth` namespace identifier.

**GlideOAuthClient - getToken(String requestID, String oauthProfileID)**
Retrieves the access and refresh tokens for the client.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>requestID</td>
<td>String</td>
<td>Request ID from the OAuth Requestor Profile [oauth_requestor_profile] table, which references the OAuth Entity Profile [oauth_entity_profile] table.</td>
</tr>
</tbody>
</table>

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oauthProfileID</td>
<td>String</td>
<td>OAuth profile ID from the OAuth Entity Profile [oauth_entity_profile] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideOAuthToken</td>
<td>The access and refresh tokens for the client.</td>
</tr>
</tbody>
</table>

This example code shows how to retrieve access and refresh tokens from the instance database.

```java
function dumpToken(token) {
    if(token) {
        gs.info("AccessToken:" + token.getAccessToken());
        gs.info("AccessTokenExpiresIn:" + token.getExpiresIn());
        gs.info("RefreshToken:" + token.getRefreshToken());
    }
}

var oAuthClient = new sn_auth.GlideOAuthClient();
var token = oAuthClient.getToken('248e3017c302301089a7dd5c2840dda5',
 '9c4e78d3c302301089a7dd5c2840dd76');
dumpToken(token);
```

Output:

```
*** Script:
  AccessToken:6MRxD3TRYYViaoKr-JCy3KiaObPu4C9k8afo3MYf9q8zDyHQr8UzMSM3Md2alfaES1rzSYe5ydqgbOwpm7TA
  AccessTokenExpiresIn:1207
  RefreshToken:sc0iTK-0PcVkr14HXPM3vT0FyOPO8iCqC10huQoDSSLBGUSnmEv_fUfJzGWCBb_StsXlOz6r8qF-hRhURWTA
```

**GlideOAuthClient - requestToken(String clientId, String jsonString)**

Retrieves the token for the client, with the request parameters encoded in JSON format.
This example shows a resource owner password grant type request, with request parameters encoded in JSON format.

```java
var oAuthClient = new GlideOAuthClient();
var params = {grant_type: "password", username: "itil", password: 'itil'};
var json = new JSON();
var text = json.encode(params);
var tokenResponse = oAuthClient.requestToken('TestClient', text);
var token = tokenResponse.getToken();
gs.log("AccessToken:" + token.getAccessToken());
gs.log("AccessTokenExpiresIn:" + token.getExpiresIn());
gs.log("RefreshToken:" + token.getRefreshToken());
```

**GlideOAuthClient - requestTokenByRequest(String clientName, GlideOAuthClientRequest request)**

Retrieves the token for the client, with the client name and the request set into a GlideOAuthClientResponse object.
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideOAuthClientResponse</td>
<td>The token for the client.</td>
</tr>
</tbody>
</table>

GlideOAuthClient - revokeToken(String clientName, String accessToken, String refreshToken, GlideOAuthClientRequest request)

Revolves the access or refresh token for the client, with the request and optional header parameters set into a GlideOAuthClientRequest object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clientName</td>
<td>String</td>
<td>The client name.</td>
</tr>
<tr>
<td>accessToken</td>
<td>String</td>
<td>The access token.</td>
</tr>
<tr>
<td>refreshToken</td>
<td>String</td>
<td>The refresh token.</td>
</tr>
<tr>
<td>request</td>
<td>GlideOAuthClientRequest</td>
<td>The request.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideOAuthClientResponse</td>
<td>The token for the client.</td>
</tr>
</tbody>
</table>

GlideOAuthClientRequest - Scoped, Global

Use these methods for handling OAuth client requests.

This API can be used in global and scoped scripts. In scoped scripts use the `sn_auth` namespace identifier.

GlideOAuthClientRequest - getGrantType()

Retrieves the grant type.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The grant type.</td>
</tr>
</tbody>
</table>

**GlideOAuthClientRequest - getHeader(String name)**

Retrieves the HTTP headers for the string you provide.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the parameter.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StringMap</td>
<td>The string map with the HTTP headers.</td>
</tr>
</tbody>
</table>

**GlideOAuthClientRequest - getHeaders()**

Retrieves the HTTP headers.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>StringMap</td>
<td>The string map with the HTTP headers.</td>
</tr>
</tbody>
</table>

**GlideOAuthClientRequest - getParameter(String name)**

Retrieves the parameters for the parameter name you provide.
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The parameter name for which you want the parameters.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The parameters.</td>
</tr>
</tbody>
</table>

**GlideOAuthClientRequest - getPassword()**

Retrieves the password.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The password.</td>
</tr>
</tbody>
</table>

**GlideOAuthClientRequest - getRefreshToken()**

Retrieves the refresh token.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The refresh token.</td>
</tr>
</tbody>
</table>
**GlideOAuthClientRequest - getScope()**
Retrieves the scope.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>none</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

**GlideOAuthClientRequest - getUserName()**
Retrieves the user name.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>none</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

**GlideOAuthClientRequest - setGrantType(String grantType)**
Sets the grant type for the string you provide.

⚠️ **Note:** You only need to set the grant type if it is not already defined in the OAuth provider profile.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>name</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideOAuthClientRequest - setHead(String name, String value)**

Retrieves the HTTP headers for the string you provide.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the parameter.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The value of the parameter.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideOAuthClientRequest - setParameter(String name, String value)**

Sets the parameters for the name:value pair of strings you provide.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The parameter name for which you want the parameters.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The value of the parameter.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideOAuthClientRequest - setPassword(String password)**

Sets the password with the string you provide.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>password</td>
<td>String</td>
<td>The user name.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideOAuthClientRequest - setRefreshToken(String refreshToken)

Sets the refresh token with the string you provide.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>refreshToken</td>
<td>String</td>
<td>The refresh token.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows a resource owner password grant type request.

```javascript
var tokenRequest = new GlideOAuthClientRequest();
tokenRequest.setGrantType("password");
tokenRequest.setUserName("itil");
tokenRequest.setPassword("itil");
tokenRequest.setScope(null);

var oAuthClient = new GlideOAuthClient();
var tokenResponse = oAuthClient.requestToken("TestClient", tokenRequest);
gs.log("Error:"+ tokenResponse.getErrorMessage());

var token = tokenResponse.getToken();
if(token){
gs.log("AccessToken:"+ token.getAccessToken());
gs.log("AccessTokenExpiresIn:"+ token.getExpiresIn());
}
This example shows a refresh token grant type request.

```javascript
var tokenRequest = new GlideOAuthClientRequest();
tokenRequest.setGrantType("refresh_token");

// Set refresh token
var oAuthClient = new GlideOAuthClient();
tokenRequest.setRefreshToken("N-GtdSVLkWP_Cr-TysXdmNy59ZYaJmu5ZaS4YaSluXDm0kCkInEnu-hwM5SsGYSFw+jxauVmoaq7xJNoalXFQ");
tokenRequest.setScope(null);

var oAuthClient = new GlideOAuthClient();
tokenResponse = oAuthClient.requestToken("TestClient", tokenRequest);

gs.log("Error:" + tokenResponse.getErrorMessage());
token = tokenResponse.getToken();
if (token){
    gs.log("AccessToken:" + token.getAccessToken());
    gs.log("AccessTokenExpiresIn:" + token.getExpiresIn());
    gs.log("AccessTokenSysID:" + token.getAccessTokenSysID());
    gs.log("RefreshToken:" + token.getRefreshToken());
    gs.log("RefreshTokenSysID:" + token.getRefreshTokenSysID());
}
```

### GlideOAuthClientRequest - setScope(String scope)

Sets the scope for the string you provide.

⚠️ **Note:** You only need to set the scope if it is not already defined in the OAuth provider.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scope</td>
<td>String</td>
<td>The scope.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### GlideOAuthClientRequest - setUserName(String userName)

Sets the user name with the string you provide.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>userName</td>
<td>String</td>
<td>The user name.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

#### GlideOAuthClientResponse - Scoped, Global

Use these methods for handling OAuth client responses.

This API can be used in global and scoped scripts. In scoped scripts use the `sn_auth` namespace identifier.

#### GlideOAuthClientResponse - getBody()

Retrieves all of the response information, including instance information.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The response information.</td>
</tr>
</tbody>
</table>

#### GlideOAuthClientResponse - getContentType()

Retrieves the HTTP response content header from an external OAuth provider.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Returns</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>GlideOAuthClientResponse - getErrorMessage()</td>
<td>String</td>
<td>The HTTP response header.</td>
</tr>
</tbody>
</table>

GlideOAuthClientResponse - getErrorMessage()
Retrieves the error message if authentication is not successful.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The error message.</td>
</tr>
</tbody>
</table>

GlideOAuthClientResponse - getResponseCode()
Retrieves the HTTP response code from the external OAuth provider.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The HTTP response code.</td>
</tr>
</tbody>
</table>

GlideOAuthClientResponse - getResponseParameters()
Retrieves the error message if authentication is not successful.
GlideOAuthClientResponse - getToken()
Retrieves the refresh token.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>none</td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MapString</td>
<td>The response content.</td>
</tr>
</tbody>
</table>

GlideOAuthToken - Scoped, Global
Use the GlideOAuthToken methods for retrieving OAuth access token and information about the access token.

This API can be used in global and scoped scripts. In scoped scripts use the sn_auth namespace identifier.

GlideOAuthToken - getAccessToken()
Retrieves the access token associated with the GlideOAuthToken object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Access token.</td>
</tr>
</tbody>
</table>

This example code shows how to retrieve access and refresh tokens from the instance database. See also GlideOAuthClient.

```javascript
function dumpToken(token) {
    if(token) {
        gs.info("AccessToken:" + token.getAccessToken());
        gs.info("AccessTokenExpiresIn:" + token.getExpiresIn());
        gs.info("RefreshToken:" + token.getRefreshToken());
    }
}

var oAuthClient = new sn_auth.GlideOAuthClient();
var token = oAuthClient.getToken('248e3017c302301089a7dd5c2840dda5',
    '9c4e78d3c302301089a7dd5c2840dd76');
dumpToken(token);
```

Output:

```text
*** Script: 
   AccessToken:6MRxD3TRYYViakR-JCy3Kia0xBPu4C9k8oao3MYf9q8z3yHq8Uz3M3D2afal7ES1rzSYe5ydqgbOWpm7TA
*** Script: AccessTokenExpiresIn:1207
*** Script: 
   RefreshToken:sc0iTK-0PcVr16HXP3vT0Fy0PO81CqC10huQ00DSSLBGUSnEv_fUfJzGWCBb_StsXIOz6r8qF-hRhURWTA
```

GlideOAuthToken - getAccessTokenSysID()

Deprecated. Retrieves the sys_id of the token ID associated with the GlideOAuthToken object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the access token.</td>
</tr>
</tbody>
</table>

**GlideOAuthToken - getExpiresIn()**

Retrieves the lifespan of the access token associated with the GlideOAuthToken object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number (Long)</td>
<td>Lifespan of the token.</td>
</tr>
<tr>
<td>Unit: Seconds</td>
<td></td>
</tr>
</tbody>
</table>

This example code shows how to retrieve access and refresh tokens from the instance database. See also GlideOAuthClient.

```javascript
function dumpToken(token) {
  if(token) {
    gs.info("AccessToken:" + token.getAccessToken());
    gs.info("AccessTokenExpiresIn:" + token.getExpiresIn());
    gs.info("RefreshToken:" + token.getRefreshToken());
  }
}

var oAuthClient = new sn_auth.GlideOAuthClient();
var token = oAuthClient.getToken('248e3017c302301089a7dd5c2840dda5',
  '9c4e78d3c302301089a7dd5c2840dd76');
dumpToken(token);
```

Output:

```plaintext
*** Script:***
AccessToken:6MRxD3TRYYvIaoKr-JCy3KiaOxBPu4C9k8oaf03MYf9q8zDYHqr8UZnSM3Md2alfaES1rzSYe5ydqgHwpm7TA
```

### GlideOAuthToken - getRefreshToken()

Refreshes the token associated with the GlideOAuthToken object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Refreshed token.</td>
</tr>
</tbody>
</table>

This example code shows how to retrieve access and refresh tokens from the instance database. See also GlideOAuthClient.

```javascript
function dumpToken(token) {
    if(token) {
        gs.info("AccessToken:" + token.getAccessToken());
        gs.info("AccessTokenExpiresIn:" + token.getExpiresIn());
        gs.info("RefreshToken:" + token.getRefreshToken());
    }
}

var oAuthClient = new sn_auth.GlideOAuthClient();
var token = oAuthClient.getToken('248e3017c302301089a7dd5c2840dda5', '9c4e78d3c302301089a7dd5c2840dd76');
dumpToken(token);
```

**Output:**

```plaintext
*** Script: AccessTokenExpiresIn:1207
 *** Script: AccessToken:6MRxD3TRYYViakKr-JCy3K1a0xBPu4C9k8oaf03Myf9q8zqfHq8UzMSM3Md2a1faES1rzSYe5ydqg
bOwpm7TA
 *** Script: AccessToke
```
GlideOAuthToken - getRefreshTokenSysID()

Deprecated. Retrieves the sys_id of the refresh token.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the refresh token.</td>
</tr>
</tbody>
</table>

GlideOAuthToken - getScope()

Retrieves the token scope, which is the amount of access granted by the access token.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Scope of the access token.</td>
</tr>
</tbody>
</table>

GlidePluginManager - Scoped

The scoped GlidePluginManager API provides a method for determining if a plugin has been activated.

**Scoped GlidePluginManager - isActive(String pluginID)**

Determines if the specified plugin has been activated.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pluginID</td>
<td>String</td>
<td>Unique plugin identifier.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates if the plugin is active.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Plugin is active.</td>
</tr>
<tr>
<td></td>
<td>• false: Plugin is inactive.</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('sys_plugins');
var queryString = "active=0^ORactive=1";
now_GR.addEncodedQuery(queryString);
now_GR.query();
var pMgr = new GlidePluginManager();

while (now_GR.next()) {
    var name = now_GR.getValue('name');
    var pID = now_GR.getValue('source');
    var isActive = pMgr.isActive(pID);
    if (isActive)
        gs.info('The plugin ' + name + ' is active');
}
```

Output:

The plugin Country Lookup Data is active
The plugin Database Replication is active
The plugin REST API Provider is active
The plugin Ten Cool Things is active

GlideQuery - Scoped, Global

The GlideQuery API is an alternative to GlideRecord to perform CRUD operations on record data from server-side scripts.

The GlideQuery API lets you:
• Use standard JavaScript objects and types for queries and results.
• Quickly diagnose query errors with additional checks and clear error messages.
• Simplify your code by avoiding boiler-plate query patterns.
• Avoid common performance issues without needing deeper knowledge of GlideRecord.

Use the GlideQuery API in scoped or global server-side scripts. When used within a scoped app, it must be prefixed with the global scope.

```javascript
new global.GlideQuery('sys_user')
// ...
```

This API requires the GlideQuery [com.sn_glidequery] plugin.

**Implementation**

This API works together with the Stream and Optional APIs in a builder pattern where the method calls chain together, each method building on the returned result of the previous method. Use methods to define the attributes of the query. The methods do not execute until you call a terminal method, a method that returns a query result, allowing you to define the requirements of the query before executing it.

If the query returns a single record, the system wraps the result in an Optional object. If the query returns a stream of records, the system wraps the result in a Stream object. These objects let you manage the result using a set of methods in each API.

For example, here's a script that performs a query on the Task table and groups the records by priority and returns groups with total reassignments greater than four.

```javascript
var query = new global.GlideQuery('task')
    .where('active', true) //Returns new GlideQuery object with a "where" clause.
    .groupBy('priority') //Returns new GlideQuery object with a "group by" clause.
    .aggregate('sum', 'reassignment_count') //Returns new GlideQuery object with a "sum(reassignment_count)" clause.
    .having('sum', 'reassignment_count', '>', 4) //Returns new GlideQuery object with a "having reassignment_count > 4" clause.
    .select() //Returns a stream of records wrapped in a Stream object.
    .toArray(10); //Terminal method in the Stream class that executes the query and returns the result.
```
Error handling

The GlideQuery API throws an error when your query has a problem, and includes a clear explanation to help guide you. GlideQuery checks for:

- Invalid fields
- Invalid value types for a field
- Invalid values for choice fields
- Invalid query operators

For example, this code sample would throw an error because the queried field does not exist in the table.

```javascript
new global.GlideQuery('task')
  .where('id', '4717dfe5a9fe198100450448b2404c16') // should be 'sys_id'
  .select('description', 'severity')
  .toArray(100);
// Error: Unable to find field 'id' in table 'task'. Known fields: active, activity_due, ...
```

This code sample would throw an error because the data type of one of the arguments is incorrect.

```javascript
new global.GlideQuery('task')
  .where('priority', 'one') // priority is an integer (should be 1)
  .select('description', 'severity')
  .toArray(100);
// Error: Unable to match value ['one'] with field 'priority' in table 'task'. Expecting type 'integer'
```

Reuse

Because GlideQuery objects are immutable, you can reuse them later in other parts of your code. For example, this script creates a query and then uses the GlideQuery object later to generate a report.

```javascript
var highPriorityTasks = new global.GlideQuery('task')
  .where('active', true)
  .where('priority', 1);

generateReport(highPriorityTasks);
notifyOwners(highPriorityTasks);
var avgReassignmentCount = highPriorityTasks
  .avg('reassignment_count')
  .orElse(0)
```
Limitations

The GlideQuery API does not support:

- Reading or writing to tables that do not allow access from other scopes.
- Reading encoded queries.
- GlideDate or GlideDateTime objects, which are read as JavaScript strings.
- FX Currency fields.
- Queries with ambiguous conditional logic. For example, the following query is unclear because the system does not know whether to execute (active = true AND name != null) OR last_name = Luddy OR active = true AND (name != null OR last_name = Luddy).

```javascript
var user = new global.GlideQuery('sys_user')
  .where('active', true)
  .whereNotNull('name')
  .orWhere('last_name', 'Luddy')
  .selectOne()
  .get()
```

See the `where()` method to understand how to nest a child query instead.

ℹ️ Note: Because the GlideQuery API converts GlideRecord objects into standard JavaScript objects, it may take longer to execute queries. To reduce performance issues, avoid creating loops that iterate over large numbers of records.

GlideQuery - GlideQuery(String table)

Instantiates a GlideQuery object used to build and execute record queries.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>Table to query.</td>
</tr>
</tbody>
</table>

This example instantiates a query of the User table.

```javascript
var query = new global.GlideQuery('sys_user');
```

GlideQuery - aggregate(String aggregateType, String field)

Aggregates a field using a specified aggregation function.
Use this method to build queries that aggregate against multiple fields or use multiple aggregate functions, or if you must use the `groupBy()` method. If you only want to aggregate against one field with one function, and you don’t need to use `groupBy()`, then use one of these methods instead:

- `avg()`
- `min()`
- `max()`
- `count()`

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aggregateType</code></td>
<td>String</td>
<td>The type of aggregation function to perform. Options include:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>min</code>: Returns the smallest value of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>max</code>: Returns the largest value of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>sum</code>: Returns the sum of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>avg</code>: Returns the average of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <code>count</code>: Returns the number of number of matching records.</td>
</tr>
<tr>
<td><code>field</code></td>
<td>String</td>
<td>Field on which to perform the operation.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>

This example performs a query on the Task table that groups the records by priority, adds the numbers in the reassignment count field for each group, and returns groups with total reassignments greater than four.

```javascript
var query = new global.GlideQuery('task')
    .where('active', true) //Returns the GlideQuery object to add more attributes to the query.
    .groupBy('priority') //Returns the GlideQuery object to add more attributes to the query.
```
$.aggregate('sum', 'reassignment_count') //Returns the GlideQuery object to add more attributes to the query.
$.having('sum', 'reassignment_count', '>', 4) //Returns the GlideQuery object to add more attributes to the query.
$.select() //Returns a stream of records wrapped in a Stream object.
$.toArray(10); //Terminal method in the Stream class that executes the query and returns the result.

gs.info(JSON.stringify(query, null, 2));

**Output:**

```json
[
  {
    "group":{
      "priority":1
    },
    "sum":{
      "reassignment_count":11
    }
  },
  {
    "group":{
      "priority":3
    },
    "sum":{
      "reassignment_count":6
    }
  },
  {
    "group":{
      "priority":5
    },
    "sum":{
      "reassignment_count":5
    }
  }
]
```

**GlideQuery - avg(String field)**

Returns the aggregate average of a given numeric field.

You can only use this method on fields of the following types:
• Integer
• Long
• Floating Point Number
• Double
• Currency

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Field on which to perform the operation.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Object that contains the aggregate average of the given field.</td>
</tr>
</tbody>
</table>

This example shows how to return the average number of faults in the cmdb_ci table.

```javascript
var faults = new global.GlideQuery('cmdb_ci')
  .avg('fault_count')
  .orElse(0);

gs.info(JSON.stringify(faults));
```

Output:

```
0.0037
```

**GlideQuery - count()**

Returns the number of records that match the query.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of records that match the query.</td>
</tr>
</tbody>
</table>

This example returns the number of active records in the User table.

```javascript
var userCount = new global.GlideQuery('sys_user')
  .where('active', true)
  .count();
```

Output:

612

**GlideQuery - deleteMultiple()**

Deletes all records in the table specified by the preceding Where clauses.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This example deletes all active records in the User table where the last name is Jeter.

```javascript
var query = new global.GlideQuery('sys_user')
  .where('active', true)
  .where('last_name', 'Jeter')
  .deleteMultiple();
```

**GlideQuery - disableAutoSysFields()**

Disables updating system fields, or fields with a name that starts with the `sys` prefix, such as `sys_created_on`, `sys_updated_on`, and `sys_mod_count`. Only applies to the specified query.
This example adds a record to the task table, but does not set system fields. Without calling this method, the below example would update sys_updated_on, sys_mod_count, and so on.

```javascript
var query = new global.GlideQuery('task')
  .disableAutoSysFields()
  .insert({ description: 'example', priority: 1 });
```

**GlideQuery - disableWorkflow()**

Disables any business rules, flows, workflows, or audit records that would run or be created as the result of the query.

This example updates multiple records in the Task table without triggering any automatic business processes.

```javascript
var query = new global.GlideQuery('task')
  .disableWorkflow()
  .where('active', true)
  .updateMultiple({ priority: 1 });
```
GlideQuery - forceUpdate()

Forces a database update even when no record changes are made. For example, you can use this method to force a business rule to execute.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>

This example force updates Task records with a certain sys_id.

```javascript
var forceUpdate = new global.GlideQuery('task')
  .forceUpdate()
  .where('sys_id', taskId)
  .update()
```

GlideQuery - get(String key, Array selectedFields)

Returns a single record from the query.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Sys_id of the record to return.</td>
</tr>
<tr>
<td>selectedFields</td>
<td>Array</td>
<td>Optional. Additional fields to return in the result. Default: The system always returns the sys_id.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Object used to interact with a single record.</td>
</tr>
</tbody>
</table>

Example that returns a record based on sys_id.
var user = new global.GlideQuery('sys_user')
  .get('5137153cc611227c000bbd1bd8cd2005', ['first_name', 'last_name'])  //Returns an Optional object.
  .orElse({ first_name: 'Default', last_name: 'User' });  //Method in the Optional class to return a default value.

gs.info(JSON.stringify(user, null, 2));

Output:

{  
  "sys_id":"5137153cc611227c000bbd1bd8cd2005",
  "first_name":"Fred",
  "last_name":"Luddy"
}

**GlideQuery - getBy(Object keyValues, Array selectedFields)**

Returns an Optional object containing a single record based on a set of name-value pairs to query by. Assumes the '=' operator for each name-value pair.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>keyValues</td>
<td>Object</td>
<td>Object where the keys are the name of the fields, and the values are the values to query for.</td>
</tr>
<tr>
<td>selectedFields</td>
<td>Array</td>
<td>Optional. Additional fields to return in the result. Default: The system always returns the sys_id.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Object used to interact with a single record.</td>
</tr>
</tbody>
</table>

**Example that returns a record by querying for a user's name.**

```javascript
var user = new global.GlideQuery('sys_user')
  .getBy(
    {  
      first_name: 'Fred',
      last_name: 'Luddy'
    },  
    ['first_name', 'last_name', 'city', 'active']  
  )  // select first_name, last_name, city, active
  .orElse(
    {}  
  );
```
first_name: 'Nobody',
last_name: 'Found',
city: 'Nowhere',
active: false
});

gs.info(JSON.stringify(user, null, 2));

Output:

{
  "first_name":"Fred",
  "last_name":"Luddy",
  "city":null,
  "active":true,
  "sys_id":"5137153cc611227c000bbd1bd8cd2005"
}

**GlideQuery - groupBy(String fields)**

Groups the query results by a designated field or fields.

You must use this method with the `aggregate()` method.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fields</td>
<td>String or Array of Strings</td>
<td>Field or fields to group the results by.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>

This example performs a query on the Task table that groups the records by priority, adds the numbers in the reassignment count field for each group, and returns groups with total reassignments greater than four.

```javascript
var query = new global.GlideQuery('task')
  .where('active', true) //Returns the GlideQuery object to add more attributes to the query.
```

.groupBy('priority') //Returns the GlideQuery object to add more attributes to the query.
.aggregate('sum', 'reassignment_count') //Returns the GlideQuery object to add more attributes to the query.
.having('sum', 'reassignment_count', '>', 4) //Returns the GlideQuery object to add more attributes to the query.
.select() //Returns a stream of records wrapped in a Stream object.
.toArray(10); //Terminal method in the Stream class that executes the query and returns the result.

gs.info(JSON.stringify(query, null, 2));

Output:

[  
  {  
    "group":{  
      "priority":1  
    },  
    "sum":{  
      "reassignment_count":11  
    }  
  },  
  {  
    "group":{  
      "priority":3  
    },  
    "sum":{  
      "reassignment_count":6  
    }  
  },  
  {  
    "group":{  
      "priority":5  
    },  
    "sum":{  
      "reassignment_count":5  
    }  
  }  
]
GlideQuery - having(String aggregateType, String field, String operator, Number value)

Filters aggregate groups so that you can display only groups of results that match a specified condition.

Must use this method with the aggregate() or groupBy() methods.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggregateType</td>
<td>String</td>
<td>The type of aggregation function to perform. Options include:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• min: Returns the smallest value of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• max: Returns the largest value of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• sum: Returns the sum of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• avg: Returns the average of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• count: Returns the number of number of matching records.</td>
</tr>
<tr>
<td>field</td>
<td>String</td>
<td>Field on which to perform the operation.</td>
</tr>
<tr>
<td>operator</td>
<td>String</td>
<td>Numeric operator to use in the operation. Options include:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &gt;: Greater than.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &lt;: Less than.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &gt;=: Greater than or equal to.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &lt;=: Less than or equal to.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• =: Equal to.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• !=: Not equal to.</td>
</tr>
<tr>
<td>value</td>
<td>Number</td>
<td>Number value to use in the operation.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>
This example performs a query on the Task table that groups the records by priority, adds the numbers in the reassignment count field for each group, and returns groups with total reassignments greater than four.

```javascript
var query = new global.GlideQuery('task')
    .where('active', true) //Returns the GlideQuery object to add more attributes to the query.
    .groupBy('priority') //Returns the GlideQuery object to add more attributes to the query.
    .aggregate('sum', 'reassignment_count') //Returns the GlideQuery object to add more attributes to the query.
    .having('sum', 'reassignment_count', '>', 4) //Returns the GlideQuery object to add more attributes to the query.
    .select() //Returns a stream of records wrapped in a Stream object.
    .toArray(10); //Terminal method in the Stream class that executes the query and returns the result.

gs.info(JSON.stringify(query, null, 2));
```

Output:

```json
[
  {
    "group": {
      "priority": 1
    },
    "sum": {
      "reassignment_count": 11
    }
  },
  {
    "group": {
      "priority": 3
    },
    "sum": {
      "reassignment_count": 6
    }
  },
  {
    "group": {
      "priority": 5
    },
    "sum": {
      "reassignment_count": 5
    }
  }
]
```
GlideQuery - insert(Object keyValues, Object selectedFields)

Inserts a record and returns an Optional object containing the record.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>keyValues</td>
<td>Object</td>
<td>Object containing name-value pairs to insert into the record. Unspecified fields will be null.</td>
</tr>
<tr>
<td>selectedFields</td>
<td>Array</td>
<td>Optional. Additional fields to return in the result. Default: The system always returns the sys_id.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Object used to interact with a single record.</td>
</tr>
</tbody>
</table>

This example shows how to insert a record based on a user's first and last name.

```javascript
var fred = new global.GlideQuery('sys_user')
    .insert({ first_name: 'Fred', last_name: 'Luddy' })
    .get();
gs.info(JSON.stringify(fred, null, 2));
```

**Output:**

```json
{
    "sys_id": "cf16eed0e82a9010f8778bda83d255d2",
    "first_name": "Fred",
    "last_name": "Luddy"
}
```

GlideQuery - insertOrUpdate(Object changes, Object selectedFields)

Updates an existing record, or inserts a new record if one does not already exist.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>changes</td>
<td>Object</td>
<td>Object containing name-value pairs to update or insert into the record.</td>
</tr>
<tr>
<td>selectedFields</td>
<td>Array</td>
<td>Optional. Additional fields to return in the result. Default: The system always returns the sys_id.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Object used to interact with a single record.</td>
</tr>
</tbody>
</table>

This example shows how to insert a new record that does not already exist in the system.

```javascript
// insert a new record
var user = new GlideQuery('sys_user')
  .insertOrUpdate({
    first_name: 'George',
    last_name: 'Griffey'
  })
  .orElse(null);
```

This example shows how to update an existing record.

```javascript
// update existing record
var user = new global.GlideQuery('sys_user')
  .insertOrUpdate({
    sys_id: '2d0efd6c73662300bb513198caf6a72e',
    first_name: 'George',
    last_name: 'Griffey'
  })
  .orElse(null);
```

### GlideQuery - limit(Number limit)

Limits the number of records returned in a query.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>limit</td>
<td>Number</td>
<td>Number of records to return.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>

This example shows how to limit the results returned to five records.

```javascript
var incidents = new global.GlideQuery('incident')
  .limit(5)
  .select('priority', 'description')
  .toArray(100);

gs.info(JSON.stringify(incidents, null, 2));
```

Output:

```json
[
  {
    "priority": 3,
    "description": "I am unable to connect to the email server. It appears to be down.",
    "sys_id": "1c741bd70b2322007518478d83673af3"
  },
  {
    "priority": 3,
    "description": "My computer is not detecting the headphone device. It could be an issue with the USB port.",
    "sys_id": "1c83270673202302728660c4cf6a7b9"
  },
  {
    "priority": 1,
    "description": "I can't remember my password and need to log in. Can someone reset my password asap? I am blocked on several urgent items until I can log in again.",
    "sys_id": "46b66a40a9fe198101f243dfbc79033d"
  },
  {
    "priority": 4,
    "description": "Currently running 10GR1 and need to upgrade to 10GR2."
  },
  {
    "priority": 3,
    "description": "I'm replacing my old phone with a Blackberry and require assistance to get it set up. I'd like to get the files and contacts transferred to the new phone and need help getting the two factor authentication app set up on it."
  }
]```
GlideQuery - max(String field)
Returns the aggregate maximum of a given field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Field on which to perform the operation.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Object used to interact with a single record.</td>
</tr>
</tbody>
</table>

This example shows how to return the maximum value, or highest alphanumerical value, of a given field.

```javascript
var name = new global.GlideQuery('sys_user')
    .max('last_name')
    .orElse('');

gs.info(JSON.stringify(name));
```

Output:

"Zortman"

GlideQuery - min(String field)
Returns the aggregate minimum of a given field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Field on which to perform the operation.</td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Object used to interact with a single record.</td>
</tr>
</tbody>
</table>

This example shows how to return the minimum value, or lowest alphanumeric value, of a given field.

```javascript
var name = new global.GlideQuery('sys_user')
    .min('last_name')
    .orElse('');
gs.info(JSON.stringify(name));
```

Output:

"Abel"

**GlideQuery - orderBy(String fields)**

Orders the returned result in ascending order by a given field.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fields</td>
<td>String</td>
<td>Comma-delimited fields to order the result by in ascending order.</td>
</tr>
</tbody>
</table>

This example shows how to order results in ascending order by record number.

```javascript
var query = new global.GlideQuery('incident')
    .orderBy('number')
    .limit(5)
    .select('priority', 'description')  //Returns a stream of records wrapped in a Stream object.
    .toArray(100);  //Terminal method in the Stream class that executes the query and returns the result.
gs.info(JSON.stringify(query, null, 2));
```
Output:

```json
[
  {
    "priority":1,
    "description":"User can't access email on mail.company.com.",
    "sys_id":"9c573169c611228700193229fff72400"
  },
  {
    "priority":1,
    "description":"User can't get to any of his files on the file server.",
    "sys_id":"9d385017c611228701d22104cc95c371"
  },
  {
    "priority":1,
    "description":"I just moved from floor 2 to floor 3 and my laptop cannot connect to any wireless network.",
    "sys_id":"e8caedc0a80164017df472f39eae1"
  },
  {
    "priority":1,
    "description":"User forgot their email password.",
    "sys_id":"9d3c1197c611228701cd1d94bc32d76d"
  },
  {
    "priority":1,
    "description":"Watcher daemon detected that the CPU was 100% busy for more than 10 minutes",
    "sys_id":"e8e875b0c0a80164009dc852b4d677d5"
  }
]
```

GlideQuery - orderByDesc(String fieldOrAggregate, String field)

Orders the returned result in descending order by a given field.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldOrAggregate</td>
<td>String</td>
<td>If the query does not use the aggregate() method, pass the field to order the results by. If the query uses the aggregate() method, pass the type of aggregation function to perform. Options include:</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>• <strong>min</strong>: Returns the smallest value of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>max</strong>: Returns the largest value of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>sum</strong>: Returns the sum of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>avg</strong>: Returns the average of all matching records.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>count</strong>: Returns the number of number of matching records.</td>
</tr>
<tr>
<td>field</td>
<td>String</td>
<td>Optional. Field to order the result by in descending order. Required for queries using the <code>aggregate()</code> method.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>

This example shows how to order the result in descending order by number.

```javascript
var query = new global.GlideQuery('incident')
    .orderByDesc('number')
    .select('number', 'description')
    .limit(5)
    .toArray(100);

gs.info(JSON.stringify(query, null, 2));
```

**Output:**

```json
[
  {
    "number":"INC0010112",
    "description":null,
    "sys_id":"552c48888c033300964f4932b03eb092"
  },
  {
    "number":"INC0010111",
    "description":null,
```
This example shows how to order an aggregate result by the sum of child incidents.

```javascript
var aggQuery = new GlideQuery('incident')
    .aggregate('sum', 'child_incidents')
    .groupBy('category')
    .orderByDesc('sum', 'child_incidents')
    .select()
    .toArray(100);

gs.info(JSON.stringify(aggQuery, null, 2));
```

Output:

```json
[
  {
    "group":{
      "category":"hardware"
    },
    "sum":{
      "child_incidents":2
    }
  },
  {
    "group":{
      "category":"software"
    },
    "sum":{
      "child_incidents":3
    }
  }
]
```
GlideQuery - orWhere(String fieldOrQuery, String operator, Any value)

Adds an OR clause to a query that returns values based on a given condition.
## Note
Precede this method with the `where()`, `whereNull()`, or `whereNotNull()` methods.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldOrQuery</td>
<td>String or GlideQuery</td>
<td>Field or another GlideQuery object used in the where clause. If passing a field, you can dot-walk to a desired value. For example, <code>company.name</code>.</td>
</tr>
<tr>
<td>operator</td>
<td>String</td>
<td>Optional. Operator used in the OR clause. If you do not pass an argument, the system uses the = operator. You do not need to include a placeholder value.</td>
</tr>
<tr>
<td>value</td>
<td>Any</td>
<td>Value used in the OR clause.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>

This example shows how to add a simple OR clause to a query.

```javascript
var query = new global.GlideQuery('sys_user')
    .where('failed_attempts', '>', 0)
    .orWhere('last_login', '<', '2019-04-15')
    .select()
    .toArray(100)

gs.info(JSON.stringify(query, null, 2));
```

### Output:

```
[
  {
    "sys_id":"005d50b536073005e0addeeffb2f4"
  },
  {
    "sys_id":"30ad318577ab2300454792718a10619e"
  },
  {
    "sys_id":"3883f4c073012302728660c4cf6a754"
  }
]
```
This example shows how to add an `orWhere` clause that contains a separate query.

```javascript
// active = true OR (title = 'Vice President' AND state = 'CA')
var query = new GlideQuery('sys_user')
  .where('active', true)
  .orWhere(new GlideQuery()
    .where('title', 'Vice President')
    .where('state', 'CA'))
  .select('name')
  .limit(5)
  .toArray(100)

gs.info(JSON.stringify(query, null, 2));
```

Output:

```json
[
  {
    "name": "survey user",
    "sys_id": "005d500b536073005e0adce6f7b12f4"
  },
  {
    "name": "Lucius Bagnoli",
    "sys_id": "02826bf03710200044e0bfc8bcbe5d3f"
  },
  {
    "name": "Jimmie Barninger",
    "sys_id": "02826bf03710200044e0bfc8bcbe5d55"
  }
]
```
GlideQuery - orWhereNotNull(String field)

Adds an OR clause that returns records that do not contain a null value in a given field.

ℹ️ **Note:** Precede this method with the `where()`, `whereNull()`, or `whereNotNull()` methods.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Field used in the query.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>

This example shows how to query the User table and return results where the first and last names are not null.

```javascript
var query = new global.GlideQuery('sys_user')
  .whereNotNull('first_name')
  .orWhereNotNull('last_name')
  .select()
  .limit(5)
  .toArray(100)

gs.info(JSON.stringify(query, null, 2));
```

**Output:**

```json
[
  {
    "sys_id":"005d500b536073005e0dadeeff7b12f4"
  }
]```
GlideQuery - orWhereNull(String field)

Adds an OR clause to a query that returns records that contain a null value in a given field.

⚠️ Note: Precede this method with the `where()`, `whereNull()`, or `whereNotNull()` methods.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Field used in the query.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>

This example shows how to query the User table and return records where the first or last names are null.

```javascript
var query = new global.GlideQuery('sys_user')
  .whereNull('last_name')
  .orWhereNull('first_name')
  .select()
  .toArray(100)

gs.info(JSON.stringify(query, null, 2));
```
Output:

```json
[
  {
    "sys_id": "1195569be81a1010f8778bda83d25585"
  },
  {
    "sys_id": "5136503cc611227c0183e96598c4f706"
  }
]
```

**GlideQuery - select(String fields)**

Returns the results of the query as a Stream object containing the specified fields.

ℹ️ **Note:** Use a terminal method in the `Stream` class to get the result of the query. For more information, see `Stream`.

You can append a flag to a field name to return the field's metadata instead of the field's value. For example, using the field name `company$DISPLAY` returns the display value of a company field. Possible flags include:

- **DISPLAY**: Returns the display value of a field.
- **CURRENCY_CODE**: Returns the currency code of a currency field. For example, `USD`.
- **CURRENCY_DISPLAY**: Returns the currency display value of a currency field. For example, `¥123.45`.
- **CURRENCY_STRING**: Returns the currency string of a currency field. For example, `JPY;123.45`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| fields | String or Array of Strings | Optional. Fields to display in the result. You can provide any number of fields as arguments, dot-walk to a desired value, or use a flag. For example:  
```java
select('first_name', 'location.city', 'company$DISPLAY');
```
or  
```java
select(['first_name', 'location.city',  
         'company$DISPLAY']);
```
|                          | Default: The system always returns the `sys_id`. |
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stream</td>
<td>Object used to interact with a stream of items such as records.</td>
</tr>
</tbody>
</table>

This example shows how to select fields to display from the query and use `$DISPLAY` to return the display value of a field.

```javascript
var stream = new global.GlideQuery('sys_user').select('first_name', 'last_name', 'company$DISPLAY').toArray(5);
gs.info(JSON.stringify(stream, null, 2));
```

**Output:**

```json
[
  {
    "first_name": "survey",
    "last_name": "user",
    "company$DISPLAY": "",
    "sys_id": "005d500b536073005e0addeeff7b12f4"
  },
  {
    "first_name": "Lucius",
    "last_name": "Bagnoli",
    "company$DISPLAY": "ACME Japan",
    "sys_id": "02826bf03710200044e0bf8bcbe5d3f"
  },
  {
    "first_name": "Jimmie",
    "last_name": "Barninger",
    "company$DISPLAY": "ACME South America",
    "sys_id": "02826bf03710200044e0bf8bcbe5d55"
  },
  {
    "first_name": "Melinda",
    "last_name": "Carleton",
    "company$DISPLAY": "ACME UK",
    "sys_id": "02826bf03710200044e0bf8bcbe5d5e"
  },
  {
    "first_name": "Jewel",
    "last_name": "Barnes"
  }
]
```
GlideQuery - selectOne(String fields)

Returns the result of the query as an Optional object containing specified fields.

Use this method when returning a single record, or to test if a record exists. If returning multiple records, use the select() method to return a Stream object.

You can append a flag to a field name to return the field's metadata instead of the field's value. For example, using the field name \texttt{company$DISPLAY} returns the display value of a company field. Possible flags include:

- \texttt{DISPLAY}: Returns the display value of a field.
- \texttt{CURRENCY\_CODE}: Returns the currency code of a currency field. For example, \texttt{USD}.
- \texttt{CURRENCY\_DISPLAY}: Returns the currency display value of a currency field. For example, \texttt{¥123.45}.
- \texttt{CURRENCY\_STRING}: Returns the currency string of a currency field. For example, \texttt{JPY;123.45}.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fields</td>
<td>String or Array of Strings</td>
<td>Optional. Fields to display in the result. You can provide any number of fields as arguments, dot-walk to a desired value, or use a flag. For example: selectOne('first_name', 'location.city', 'company$DISPLAY'); or selectOne(['first_name', 'location.city', 'company$DISPLAY']); Default: The system always returns the sys_id.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Object used to interact with a single record.</td>
</tr>
</tbody>
</table>

This example shows how to return a single record as an Optional object and display specified fields.

```javascript
var user = new global.GlideQuery('sys_user')
  .where('zip', '12345')
  .whereNotNull('last_name')
  .selectOne('first_name', 'last_name', 'company$DISPLAY')
  .get();

gs.info(JSON.stringify(user, null, 2));
```

Output:

```json
{
  "first_name": "Abel",
  "last_name": "Tuter",
  "company$DISPLAY": "ACME South America",
  "sys_id": "62826bf03710200044e0bfc8bcbe5df1"
}
```

**GlideQuery - sum(String field)**

Returns the aggregate sum of a given numeric field.

You can only use this method on fields of the following types:

- Integer
- Long
- Floating Point Number
- Double
- Currency

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Field on which to perform the operation.</td>
</tr>
</tbody>
</table>
This example shows how to return the sum of all faults in the cmdb_ci table.

```javascript
var totalFaults = new global.GlideQuery('cmdb_ci')
    .sum('fault_count')
    .orElse(0);

gs.info(JSON.stringify(totalFaults));
```

Output:

```
10
```

**GlideQuery - toGlideRecord()**

Returns a GlideRecord object that represents the current query. Returns a GlideAggregate object if the query uses the GlideQuery.aggregate() method.

After transforming the query, use the query() method in the GlideRecord or GlideAggregate classes to query the database.
GlideQuery - update(Object changes, Object selectedFields)

Updates an existing record that matches the defined conditions.

Before using this method, call the where() method to specify the conditions that a record must meet to be updated.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>changes</td>
<td>Object</td>
<td>Object containing name-value pairs to update in the record. Names must match fields in the table.</td>
</tr>
<tr>
<td>selectedFields</td>
<td>Array</td>
<td>Optional. Additional fields to return in the result. Default: The system always returns the sys_id.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>Object used to interact with a single record.</td>
</tr>
</tbody>
</table>

This example shows how to update a record with new values.

```javascript
var updateRecord = new global.GlideQuery('sys_user')
    .where('sys_id', '0a826bf03710200044e0bfc8bcbe5d7a')
    .update({ city: 'Los Angeles' });
```

GlideQuery - updateMultiple(Object changes)

Updates all existing records that match the defined conditions. Returns the number of records updated.

Before using this method, call the where() method to specify the conditions that the records must meet to be updated.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>changes</td>
<td>Object</td>
<td>Object containing name-value pairs to update in the record. Names must match fields in the table.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Object containing the number of records that were updated. Keys include:</td>
</tr>
<tr>
<td></td>
<td>• rowCount: Number of rows updated in the table.</td>
</tr>
</tbody>
</table>

This example shows how to update any records that fit a defined criteria.

```javascript
var update = new global.GlideQuery('sys_user')
  .where('active', false)
  .where('last_name', 'Griffey')
  .updateMultiple({ active: true });

gs.info(JSON.stringify(update));
```

Output:

```
{"rowCount":1}
```

**GlideQuery - where(String fieldOrQuery, String operator, Any value)**

Adds a Where clause to the query that returns values based on a given condition.

ℹ️ **Note:** Do not precede this method with the `orWhere()`, `orWhereNull()`, or `orWhereNotNull()` methods.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldOrQuery</td>
<td>String or</td>
<td>Field or another GlideQuery object used in the where clause. If passing a</td>
</tr>
<tr>
<td></td>
<td>GlideQuery</td>
<td>field, you can dot-walk to a desired value. For example, <code>company.name</code>.</td>
</tr>
<tr>
<td>operator</td>
<td>String</td>
<td>Optional. Operator used in the where clause. If you do not pass an argument,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the system uses the = operator.</td>
</tr>
<tr>
<td>value</td>
<td>Any</td>
<td>Value used in the where clause.</td>
</tr>
</tbody>
</table>
This example shows how to return records from the User table where active is true and the user last logged on after a specified date.

```javascript
var query = new global.GlideQuery('sys_user')
  .where('active', true)
  .where('last_login', '>', '2016-04-15')
  .limit(5)
  .select()
  .toArray(100)

gs.info(JSON.stringify(query, null, 2));
```

Output:

```
[
  {
    "sys_id":"b0f31e5673500010c2e7660c4cf6a711"
  },
  {
    "sys_id":"8ff5b254b33213005e3de13516a8dcf7"
  },
  {
    "sys_id":"d999e5fc77e72300454792718a10611d"
  },
  {
    "sys_id":"30ad318577ab2300454792718a10619e"
  },
  {
    "sys_id":"3883f4c0730123002728660c4cf6a754"
  }
]
```

This example shows how to return records from the Incident table where active is true and where either the priority or the severity is 1.

```javascript
// active = true AND (priority = 1 OR severity = 1)
var query = new GlideQuery('incident')
  .where('active', true)
  .where(new GlideQuery()
    .where('priority', 1)
    .or
    .where('severity', 1)
  )
  .select()
  .toArray(100)

gs.info(JSON.stringify(query, null, 2));
```
.orWhere('severity', 1))
.limit(5)
.select()
.toArray(100)

gs.info(JSON.stringify(query, null, 2));

Output:
[
  {
    "sys_id":"b0f31e5673500010c2e7660c4cf6a711"
  },
  {
    "sys_id":"8ff5b254b33213005e3de13516a8dcf7"
  },
  {
    "sys_id":"d999e5fc77e72300454792718a10611d"
  },
  {
    "sys_id":"30ad318577ab2300454792718a10619e"
  },
  {
    "sys_id":"3883f4c0730123002728660c4cf6a754"
  }
]

**GlideQuery - whereNotNull(String field)**

Returns records that do not contain a null value in a given field.

**Note:** Do not precede this method with the `orWhere()`, `orWhereNull()`, or `orWhereNotNull()` methods.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Field used in the query.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>
This example shows how to query the User table and return results where the first_name field is not null.

```javascript
var query = new global.GlideQuery('sys_user').whereNotNull('first_name').select().limit(5).toArray(100);

gs.info(JSON.stringify(query, null, 2));
```

Output:

```
[
  {
    "sys_id":"005d500b536073005e0addee7b12f4"
  },
  {
    "sys_id":"02826bf03710200044e0bfc8bcbe5d3f"
  },
  {
    "sys_id":"02826bf03710200044e0bfc8bcbe5d55"
  },
  {
    "sys_id":"02826bf03710200044e0bfc8bcbe5d5e"
  },
  {
    "sys_id":"02826bf03710200044e0bfc8bcbe5d64"
  }
]
```

**GlideQuery - whereNull(String field)**

Returns records that contain a null value in a given field.

**Note:** Do not precede this method with the `orWhere()`, `orWhereNull()`, or `orWhereNotNull()` methods.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Field used in the query.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>

This example shows how to query the User table and return records where the first or last names are null.

```javascript
var query = new global.GlideQuery('sys_user')
    .whereNull('last_name')
    .orWhereNull('first_name')
    .select()
    .toArray(100)

gs.info(JSON.stringify(query, null, 2));
```

Output:

```javascript
[
    {
        "sys_id":"1195569be81a1010f8778bda83d25585"
    },
    {
        "sys_id":"5136503cc611227c0183e96598c4f706"
    }
]
```

**GlideQuery - withAcls()**

Executes the query using the GlideRecordSecure API to securely query the database while honoring ACLs.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQuery</td>
<td>The query object being built.</td>
</tr>
</tbody>
</table>

This example shows how to execute a secure query using ACLs.
var users = new global.GlideQuery('sys_user')
    .withAcls()
    .limit(5)
    .orderByDesc('first_name')
    .select('first_name')
    .toArray(100);

gs.info(JSON.stringify(users, null, 2));

Output:

```
[
  {
    "first_name": "Zane",
    "sys_id": "16826bf03710200044e0bfc8bcbe5dbc"
  },
  {
    "first_name": "Zackary",
    "sys_id": "8a826bf03710200044e0bfc8bcbe5d69"
  },
  {
    "first_name": "Yvette",
    "sys_id": "4e826bf03710200044e0bfc8bcbe5d57"
  },
  {
    "first_name": "Winnie",
    "sys_id": "f682abf03710200044e0bfc8bcbe5d1d"
  },
  {
    "first_name": "Wilmer",
    "sys_id": "42826bf03710200044e0bfc8bcbe5d7b"
  }
]
```

**GlideQueryCondition - Global**

The GlideQueryCondition API provides additional AND or OR conditions that can be added to the current condition, allowing you to build complex queries.

Build complex queries such as:

```
category='hardware' OR category='software' AND priority='2' AND priority='1'
```

In the case of addCondition(), an implied AND is added.

This class has no constructor. A GlideQueryCondition object is returned by the following methods:
• addActiveQuery()
• addInactiveQuery()
• addJoinQuery()
• addNotNullQuery()
• addNullQuery()
• addQuery()

If there is a complicated set of AND and OR queries, a single encoded query containing all conditions simplifies the query creation. To simplify the query creation, create a query in a list view, right-click the query, and select **Copy query**. It creates a single encoded query string to return your result set. Use that string as a parameter in an `addEncodedQuery()` call.

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.

You can set the `glide.invalid_query.returns_no_rows` system property to true to have queries with invalid encoded queries return no records.

**GlideQueryCondition - addCondition(String name, String oper, Object value)**

Adds an AND condition to the current condition.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of a field.</td>
</tr>
<tr>
<td>oper</td>
<td>String</td>
<td>(Optional) The operator for the query. If you do not specify an operator, the condition uses an equals operator.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>The value to query on.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>A reference to a GlideQueryCondition that was added to the GlideRecord.</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
var qc = now_GR.addQuery('category', 'Hardware');
qc.addCondition('category', 'Network');
now_GR.addQuery('number', 'INC0000003');
now_GR.next();
now_GR.number;
gs.info(now_GR.getEncodedQuery());
```

**Scoped equivalent**

To use the `addCondition()` method in a scoped application, use the corresponding scoped method: **Scoped GlideQueryCondition - addCondition(String name, String oper, Object value).**

**GlideQueryCondition - addOrCondition(String name, String oper, Object value)**

Appends a 2-or-3 parameter OR condition to an existing GlideQueryCondition.

`addOrCondition()` works in conjunction with any of the **Scoped GlideRecord - addQuery(String name, String operator, Object value)** methods to OR the specified query parameters to the query previously constructed using `addQuery()`.

`addOrCondition()` is typically called with three parameters; table field, operator, and comparison value. It can be called with only two parameters, table field and comparison value, such as `qc.addOrCondition('category', 'software');`. The operator in this case is assumed to be "equal to".

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Field name</td>
</tr>
<tr>
<td>oper</td>
<td>String</td>
<td>(Optional) Query operator. The available values are dependent on the data type of the value parameter. Numbers:</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>• =</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• !=</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &gt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &gt;=</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &lt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &lt;=</td>
</tr>
</tbody>
</table>

Strings (must be in upper case):

• =
• !=
• IN
• STARTSWITH
• ENDSWITH
• CONTAINS
• DOESNOTCONTAIN

<table>
<thead>
<tr>
<th>Value</th>
<th>Object</th>
<th>Value on which to query (not case-sensitive).</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Note: All passed in arrays must contain a minimum of two elements. Single element arrays are not supported.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>A reference to a GlideQueryCondition that was added to the GlideRecord.</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
var qc = now_GR.addQuery('category', 'Hardware');
qc.addOrCondition('category', 'Network');
now_GR.addQuery('number','INC0000003');
now_GR.next();
now_GR.number;
gs.info(now_GR.getEncodedQuery());
```
To group AND/OR statements such as \((\text{state} < 3 \text{ OR } \text{state} > 5) \text{ AND } (\text{priority} = 1 \text{ OR } \text{priority} = 5)\) use code similar to the following:

```javascript
var myObj = new GlideRecord('incident');
var q1 = myObj.addQuery('state', '<', 3);
q1.addOrCondition('state', '>', 5);
var q2 = myObj.addQuery('priority', 1);
q2.addOrCondition('priority', 5);
myObj.query();
```

**Scoped equivalent**

To use the `addOrCondition()` method in a scoped application, use the corresponding scoped method: `Scoped GlideQueryCondition - addOrCondition(String name, String oper, Object value)`.

**GlideQueryCondition - Scoped**

The scoped GlideQueryCondition API provides additional AND or OR conditions that can be added to the current condition, allowing you to build complex queries.

Build complex queries such as:

```
category='hardware' OR category='software' AND priority='2' AND priority='1'
```

In the case of `addCondition()`, an implied AND is added.

This class has no constructor. A GlideQueryCondition object is returned by the following methods:

- `addActiveQuery()`
- `addInactiveQuery()`
- `addJoinQuery()`
- `addNotNullQuery()`
- `addNullQuery()`
- `addQuery()`

If there is a complicated set of AND and OR queries, a single encoded query containing all conditions simplifies the query creation. To simplify the query creation, create a query in a list view, right-click the query, and select **Copy query**. It creates a single encoded query string to return your result set. Use that string as a parameter in an `addEncodedQuery()` call.

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as
including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.

You can set the `glide.invalid_query.returns_no_rows` system property to true to have queries with invalid encoded queries return no records.

**Scoped GlideQueryCondition - addCondition(String name, String oper, Object value)**

Adds an AND condition to the current condition.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of a field.</td>
</tr>
<tr>
<td>oper</td>
<td>(Optional) The operator for the query. If you do not specify an operator, the condition uses an equals operator.</td>
</tr>
<tr>
<td>value</td>
<td>The value to query on.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>A reference to a GlideQueryCondition that was added to the GlideRecord.</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
var qc = now_GR.addQuery('category', 'Hardware');
qc.addCondition('category', 'Network');
now_GR.addQuery('number','INC0000003');
now_GR.next();
now_GR.number;
gs.info(now_GR.getEncodedQuery());
```

**Scoped GlideQueryCondition - addOrCondition(String name, String oper, Object value)**

Appends a two-or-three parameter OR condition to an existing GlideQueryCondition.
addOrCondition() works in conjunction with any of the `Scoped GlideRecord.addQuery(String name, String operator, Object value)` methods to OR the specified query parameters to the query previously constructed using `addQuery()`.

`addOrCondition()` is typically called with three parameters: table field, operator, and comparison value. It can be called with only two parameters, table field and comparison value, such as `qc.addOrCondition('category', 'software');`. The operator in this case is assumed to be "equal to".

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Field name</td>
</tr>
</tbody>
</table>
| oper | String| (Optional) Query operator. The available values are dependent on the data type of the value parameter. Numbers:  
  • =  
  • !=  
  • >  
  • >=  
  • <  
  • <=  
  Strings (must be in upper case):  
  • =  
  • !=  
  • IN  
  • STARTSWITH  
  • ENDSWITH  
  • CONTAINS  
  • DOESNOTCONTAIN |
| value| Object| Value on which to query (not case-sensitive). |

**Note:** All passed in arrays must contain a minimum of two elements. Single element arrays are not supported.
### GlideRecord - Client

GlideRecord is used for database operations. The client-side GlideRecord API enables the use of some GlideRecord functionality in client-side scripts, such as client scripts and UI policy scripts.

A GlideRecord contains both records and fields. Queries made with the client-side GlideRecord are executed on the server. Therefore, a request is made from the client browser to obtain the record data.

The client-side GlideRecord API is not supported in scoped applications. Instead, create a script include and use the GlideAjax API, or use the REST APIs. In addition, the client-side GlideRecord API applies ACLs based on the credentials of the user executing the script. To execute the code on the server without ACLs, use the GlideAJAX API.

### Client side GlideRecord - addOrderBy(String column)

Adds a column to order by in the query.

---

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>A reference to a GlideQueryCondition that was added to the GlideRecord.</td>
</tr>
</tbody>
</table>
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>String</td>
<td>The column by which to order the result set.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### Client side GlideRecord - `addQuery(String name, Object value)`

Adds a query to return records where the specified field name is equal to a specified value (or is in a list of values).

If you are familiar with SQL, this method is similar to the "where" clause. You can create one or more queries for a single filter by calling this method multiple times; for this method the queries are AND'ed. Once you define all of the desired queries, call the `Client side GlideRecord - query(Function responseFunction)` to execute the specified query clause (filter).

To perform an operation other than AND, use either the `addQuery(String name, Object operator, Object value)` method or the `setEncodedQuery()` method.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field to check.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>Value on which to query.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

#### Example showing multiple queries.

```javascript
var now_GR = new GlideRecord('incident');
now_GR.addQuery('priority', 4); // Priority is 4 – Low and,
now_GR.addQuery('state', 3); // State is On Hold
now_GR.query(response);
```
```javascript
function response(result) {
    while(result.next()) {
        // Print all INC with priority 4 – Low AND state is On Hold
        console.log(result.getValue('number'));
    }
}
```

Example showing how to pass a string object.

```javascript
var now_GR = new GlideRecord('incident');
now_GR.addQuery('short_description', new String('USB device not working')); // string
now_GR.addQuery('priority', 4); // number
now_GR.query(response);
```

`Client side GlideRecord - addQuery(String name, Object operator, Object value)`

Adds a filter to return records where the field meets the specified condition (field, operator, value).

If you are familiar with SQL, this method is similar to the “where” clause. You can create one or more queries for a single filter by calling this method multiple times. Once you define all of the desired queries, call the `Client side GlideRecord - query(Function responseFunction)` to execute the specified query clause (filter).

To create more complex queries, use the `setEncodedQuery()` method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field to check.</td>
</tr>
<tr>
<td>operator</td>
<td>Object</td>
<td>Query operator. The available values are dependent on the data type of the value parameter.</td>
</tr>
</tbody>
</table>
**Parameters (continued)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

**Numbers:**
- `=`
- `!=`
- `>`
- `>=`
- `<`
- `<=`

**Strings (must be in upper case):**
- `=`
- `!=`
- `IN`
- `NOT IN`
- `STARTSWITH`
- `ENDSWITH`
- `CONTAINS`
- `DOES NOT CONTAIN`
- `INSTANCEOF`

<table>
<thead>
<tr>
<th>value</th>
<th>Object</th>
<th>Value on which to query (not case-sensitive).</th>
</tr>
</thead>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>void</code></td>
<td></td>
</tr>
</tbody>
</table>

Example showing how to add multiple queries to a filter.

```javascript
var now_GR = new GlideRecord('incident');
now_GR.addQuery('priority', '<=', 2); // Priority is 2 or higher and,
now_GR.addQuery('short_description', 'CONTAINS', 'crash'); // Short description contains the word crash
now_GR.query(response);
```
function response(result) {
    while(result.next()) {
        // Print all INC with priority of 2 or higher AND short description contains "crash"
        console.log(result.getValue('number'));
    }
}

Example showing how to pass in an array to verify multiple conditions in a single query.

var priorities = [4,2];
var now_GR = new GlideRecord('incident');
now_GR.addQuery('priority', 'IN', priorities);
now_GR.query(response);

function response(result) {
    while(result.next()) {
        console.log(result.getValue('number'));
    }
}

Client side GlideRecord - deleteRecord(Function responseFunction)
Deletes the current record and calls the specified response function when complete.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>responseFunction</td>
<td>Function</td>
<td>Response function for the Ajax callback.</td>
</tr>
</tbody>
</table>

This example deletes a record and then calls the response function response to log an alert message.

var recordGR = new GlideRecord('incident');
if (recordGR.get('99ebb4156fa831005be8883e6b3ee4b9')) {
    recordGR.deleteRecord(response);
}
function response(result) {
    alert('Deleted record sys_id: ' + result.getValue('sys_id'));
}

Output

Deleted record sys_id: 99ebb4156fa831005be8883e6b3ee4b9

**Client side GlideRecord - get(Object sys_id)**

Executes a GlideRecord query for a record with the specified sys_id. This method is expected to be used to query for single records, so a next operation is performed before returning.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>Object</td>
<td>The sys_id of the record to be found.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if one or more matching records was found. False if no records were found.</td>
</tr>
</tbody>
</table>

**Client side GlideRecord - getEncodedQuery()**

Retrieves the query condition of the current result set as an encoded query string.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The encoded query as a string.</td>
</tr>
</tbody>
</table>

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Client side GlideRecord - getLimit()
Returns the limit for records to be returned by the GlideRecord query.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The limit for records to be returned by the GlideRecord query.</td>
</tr>
</tbody>
</table>

Client side GlideRecord - getTableName()
Retrieves the name of the table associated with this GlideRecord.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The table name</td>
</tr>
</tbody>
</table>

```javascript
var item = new GlideRecord('sc_request');
item.addQuery('sys_id', current.request);
item.query(itemResponse);

function itemResponse(item) {
    alert('The table is ' + item.getTableName());
}
```

Client side GlideRecord - GlideRecord(String tableName)
Creates an instance of the GlideRecord class for the specified table.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The table to be used.</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
```

### Client side GlideRecord - hasNext()

Determines if there are any more records in the GlideRecord.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if there are more records in the query set.</td>
</tr>
</tbody>
</table>

### Client side GlideRecord - insert(Function responseFunction)

Inserts a new record using the field values that have been set for the current record.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>responseFunction</td>
<td>Function</td>
<td>Function to execute once the record is inserted.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the inserted record, or null if the record was not inserted.</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
now_GR.short_description = 'Learn about GlideRecord';
var recResponse = now_GR.insert(handleResponse);
```
function handleResponse(recResponse, answer) {
    // Answer will be the sys_id of the created record or null
    alert('Newly created sys_id is - ' + answer + ' exists');
}

**Client side GlideRecord - next()**

Moves to the next record in the GlideRecord.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>False if there are no more records in the query set.</td>
</tr>
</tbody>
</table>

```javascript
var rec = new GlideRecord('incident');
rec.query(recResponse);

function recResponse(rec) {
    while (rec.next()) {
        alert(rec.number + ' exists');
    }
}
```

**Client side GlideRecord - orderBy(String column)**

Specifies an orderBy column. May be called more than once to order by multiple columns.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>String</td>
<td>The column name to be used to order the result set.</td>
</tr>
</tbody>
</table>
function UpdateProjectWBS(project) {
    var count = 0;
    var child = new GlideRecord('pm_project_task');
    child.addQuery('parent', project.sys_id);
    child.orderBy('order');
    child.orderBy('number');
    child.query(childResponse);
    g_form.addInfoMessage(count + ' Project Tasks updated');
}

function childResponse(child) {
    var len = child.getRowCount().toString().length;
    var seq = 0;
    while (child.next()) {
        count += UpdateProjectTaskWBS(child, 1, ++seq, len, ' ');
    }
}

Client side GlideRecord - query(Function responseFunction)
Runs the query against the table based on the addQuery() filter. This queries the GlideRecord table as well as any references of the table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>responseFunction</td>
<td>Function</td>
<td>The response function for the Ajax callback.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
Client side GlideRecord - setEncodedQuery(String encodedQuery)
Adds a specified encoded query string to the current query clause.

This method enables you to specify complex filters (encoded query strings) in a single query call, unlike other client-side addQuery() methods. Once you define all of the desired queries, call the Client side GlideRecord - query(Function responseFunction) to execute the specified query clause (filter). For additional information on encoded query strings, refer to Encoded query strings.

If you call this method multiple times before calling the query() method, the queries are AND'ed together.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>encodedQuery</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
now_GR.setEncodedQuery('priority=4^ORstate=3');
now_GR.query(response);

function response(result) {
    while(result.next()) {
        console.log(result.getValue('number'));
    }
}
```
Client side GlideRecord - setLimit(Number maxQuery)

Sets the limit for how many records are in the GlideRecord.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxQuery</td>
<td>Number</td>
<td>The limit for the number of records to retrieve.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideRecord - Global**

The GlideRecord API is used for database operations.

The GlideRecord API is the primary means of interfacing with the database on the server-side code. A GlideRecord is an object that contains records from a single table. Use the API to instantiate a GlideRecord object and add query parameters, filters, limits, and ordering.

For information about GlideRecordSecure, which is a class inherited from GlideRecord that performs the same functions as GlideRecord, and also enforces ACLs, see the GlideServer APIs.

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an insert(), update(), deleteRecord(), or deleteMultiple() method on bad query results can result in data loss.

You can set the glide.invalid_query.returns_no_rows system property to true to have queries with invalid encoded queries return no records.

**Retrieve values from records**

In most cases, do not use dot-walking to get values from a record. Dot-walking retrieves the entire object instead of the field value. Retrieving the object uses much more storage and might cause undesirable results when used in arrays or in Service Portal.
Instead of retrieving the entire object, you can use one of the following methods to copy the field values:

- `getValue()`
- `getDisplayValue()`

If dot-walking through a `GlideElement` object is necessary, use the `toString()` method to retrieve values. For example, you might need the current caller's manager sys_id to set another reference field. The following example shows how to get the string value instead of the entire object:

```javascript
var mgr = current.caller_id.manager.toString();
```

See also:
- `GlideAggregate`
- `GlideElement`
- `GlideQuery - Scoped, Global`

**GlideRecord - addActiveQuery()**

Adds a filter to return active records.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
</tr>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>GlideQueryCondition</td>
<td>Filter to return active records.</td>
</tr>
</tbody>
</table>

```javascript
var inc = new GlideRecord('incident');
inc.addActiveQuery();
inc.query();
```

**Scoped equivalent**

To use the `addActiveQuery()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - addActiveQuery()`.

Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
GlideRecord - addDomainQuery(Object glideRecord)

Changes the domain used for the query from the user's domain to the domain of the provided GlideRecord.

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.

You can set the `glide.invalid_query.returns_no_rows` system property to true to have queries with invalid encoded queries return no records.

This function requires the Domain Support - Domain Extensions Installer (com.glide.domain.msp_extensions.installer) plugin.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glideRecord</td>
<td>Object</td>
<td>GlideRecord from which to obtain the domain.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
//This example requires the Domain plugin be active, the Group table is the specified Domain table, and the ITIL user is in the Database Atlanta domain. //From any domain (using queryNoDomain()) look up the incidents that an ITIL user can only see //who is in the Database Atlanta domain, should expect all incidents with the global or the //Database Atlanta domain specified.
var domain = new GlideRecord('sys_user');
domain.addQuery('user_name', 'itil');
domain.queryNoDomain();
if (domain.next()) {
    var domainQuery = new GlideRecord('incident');
domainQuery.addDomainQuery(domain);
domainQuery.query();
gs.print('Number of Incidents for ITIL user: ' + domainQuery.getRowCount());
```
while (domainQuery.next())
    gs.print(domainQuery.number);
}

Scoped equivalent
This method is not available in scoped applications.

GlideRecord - addEncodedQuery(String query)
Adds an encoded query to other queries that may have been set.

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an insert(), update(), deleteRecord(), or deleteMultiple() method on bad query results can result in data loss.

You can set the glide.invalid_query.returns_no_rows system property to true to have queries with invalid encoded queries return no records.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>String</td>
<td>An encoded query string.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

var queryString = "priority=1^ORpriority=2";
var now_GR = new GlideRecord('incident');

now_GR.addEncodedQuery(queryString);
now_GR.query();
while (now_GR.next()) {
    gs.addInfoMessage(now_GR.number);
}
Scoped equivalent

To use the `addEncodedQuery()` method in a scoped application, use the corresponding scoped method: Scoped GlideRecord - `addEncodedQuery(String query)`.

GlideRecord - addFunction(Object function)

Applies a pre-defined GlideDBFunctionBuilder object to a record.

Use the GlideDBFunctionBuilder scoped class to define a function. After the function is defined, use the `addFunction(Object function)` method to apply the function to a record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>function</td>
<td>Object</td>
<td>A GlideDBFunctionBuilder object that defines a SQL operation.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var functionBuilder = new GlideDBFunctionBuilder();
var myAddingFunction = functionBuilder.add();
myAddingFunction = functionBuilder.field('order');
myAddingFunction = functionBuilder.field('priority');
myAddingFunction = functionBuilder.build();

var now_GR = new GlideRecord('incident');
now_GR.addFunction(myAddingFunction);
now_GR.addQuery(myAddingFunction, '<', 5);
now_GR.query();
while(now_GR.next())
gs.log(now_GR.getValue(myAddingFunction));
```

Output:

```plaintext
*** Script: 1
*** Script: 4
*** Script: 3
*** Script: 1
```
GlideRecord - addInactiveQuery()

Adds a filter to return inactive records. Inactive records have the active flag set to false.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>Records where the active flag is false.</td>
</tr>
</tbody>
</table>

```javascript
var inc = new GlideRecord('incident');
inc.addInactiveQuery();
inc.query();
```

### Scoped equivalent

In scoped applications use the scoped method `Scoped GlideRecord - addQuery(String name, Object value)`.

GlideRecord - addJoinQuery(String table)

Adds a filter to return records based on a relationship in a related table.

For example, find all the users that are in the database group (users via `sys_user_grmember` table). Another example would be find all problems that have an assigned incident (problems via the `incident.problem_id` relationship).

This is not a true database join; rather, `addJoinQuery()` adds a subquery. So, while the result set is limited based on the join, the only fields that you have access to are those on the base table (those which are in the table with which the GlideRecord was initialized).
Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.

You can set the `glide.invalid_query.returns_no_rows` system property to true to have queries with invalid encoded queries return no records.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>table</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>GlideQueryCondition</td>
</tr>
</tbody>
</table>

Find problems that have an incident attached. This example returns problems that have associated incidents. However, it won't pull values from the incidents that are returned as a part of the query.

```javascript
var prob = new GlideRecord('problem');
prob.addJoinQuery('incident');
prob.query();
```

Find active=false problems with associated incidents.

```javascript
// Look for Problem records
var now_GR = new GlideRecord('problem');

// That have associated Incident records
var grSQ = now_GR.addJoinQuery('incident');

// Where the Problem records are "active=false"
now_GR.addQuery('active', 'false');

// And the Incident records are "active=true"
grSQ.addCondition('active', 'true');

// Query
```
now_GR.query();

// Iterate and print results
while (now_GR.next()) {
    gs.print(now_GR.getValue('number'));
}

**Scoped equivalent**

To use the `addJoinQuery()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord – addJoinQuery(String joinTable, String primaryField, String joinTableField)**.

**GlideRecord - addJoinQuery(String table, String primaryField)**

Adds a filter to return records based on a relationship in a related table.

For example, find all the users that are in the database group (users via sys_user_grmember table). Another example would be find all problems that have an assigned incident (problems via the incident.problem_id relationship).

This is not a true database join; rather, `addJoinQuery()` adds a subquery. So, while the result set is limited based on the join, the only fields that you have access to are those on the base table (those which are in the table with which the GlideRecord was initialized).

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.

You can set the `glide.invalid_query.returns_no_rows` system property to true to have queries with invalid encoded queries return no records.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>Table name</td>
</tr>
<tr>
<td>primaryField</td>
<td>String</td>
<td>If other than sys_id, the primary field.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>Records where the relationships match.</td>
</tr>
</tbody>
</table>

Find problems that have incidents using the open_by field at the join key instead of the sys_id.

```javascript
var now_GR = new GlideRecord('problem');
now_GR.addJoinQuery('incident', 'opened_by');
now_GR.query();
```

**Scoped equivalent**

To use the `addJoinQuery()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord – addJoinQuery(String joinTable, String primaryField, String joinTableField)`.

**GlideRecord - addJoinQuery(String table, String primaryField, String joinTableField)**

Adds a filter to return records based on a relationship in a related table.

For example, find all the users that are in the database group (users via `sys_user_grmember` table). Another example would be find all problems that have an assigned incident (problems via the incident.problem_id relationship).

This is not a true database join; rather, `addJoinQuery()` adds a subquery. So, while the result set is limited based on the join, the only fields that you have access to are those on the base table (those which are in the table with which the GlideRecord was initialized).

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.

You can set the `glide.invalid_query_returns_no_rows` system property to true to have queries with invalid encoded queries return no records.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>Table name</td>
</tr>
<tr>
<td>primaryField</td>
<td>String</td>
<td>If other than sys_id, the primary field.</td>
</tr>
<tr>
<td>joinTableField</td>
<td>String</td>
<td>If other than sys_id, the field that joins the tables</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>Records where the relationships match.</td>
</tr>
</tbody>
</table>

Find problems that have incidents associated where the incident caller_id field value matches that of the problem opened_by field.

```javascript
var now_GR = new GlideRecord('problem');
now_GR.addJoinQuery('incident', 'opened_by', 'caller_id');
now_GR.query();
```

### Scoped equivalent

To use the `addJoinQuery()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord – addJoinQuery(String joinTable, String primaryField, String joinTableField)**.

### GlideRecord - addNotNullQuery(String fieldName)

Adds a filter to return records where the specified field is not null.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>GlideQueryCondition of records where the parameter field is not null.</td>
</tr>
</tbody>
</table>
var target = new GlideRecord('incident');
    target.addNotNullQuery('short_description');
    target.query(); // Issue the query to the database to get all records
    while (target.next()) {
        // add code here to process the incident record
    }

Scoped equivalent

To use the `addNotNullQuery()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - addNotNullQuery(String fieldName)`.

**GlideRecord - addNullQuery(String fieldName)**

Adds a filter to return records where the specified field is null.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field name.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>GlideQueryCondition of records where the specified field is null.</td>
</tr>
</tbody>
</table>

var target = new GlideRecord('incident');
    target.addNullQuery('short_description');
    target.query(); // Issue the query to the database to get all records
    while (target.next()) {
        // add code here to process the incident record
    }

Scoped equivalent

To use the `addNullQuery()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - addNullQuery(String fieldName)`.
GlideRecord - addQuery(String name, Object operator, Object value)

Provides the ability to build a request, which when executed, returns the rows from the specified table that match the request.

If you are familiar with SQL, this method is similar to the "where" clause. One or more addQuery() calls can be made in a single query; for this method the queries are AND'ed. If any of the query statements need to be OR'ed, use the class GlideQueryCondition - Global.

addQuery() is typically called with three parameters; table field, operator, and comparison value. It can be called with only two parameters, table field and comparison value, such as myObj.addQuery('category', 'Hardware');. The operator in this case is assumed to be "equal to".

For additional information on using queries, see Querying tables in script.

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an insert(), update(), deleteRecord(), or deleteMultiple() method on bad query results can result in data loss.

You can set the glide.invalid_query.returns_no_rows system property to true to have queries with invalid encoded queries return no records.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Table field name</td>
</tr>
</tbody>
</table>
| operator | Object   | Query operator. The available values are dependent on the data type of the value parameter. Numbers:  
|         |            | • =  
|         |            | • !=  
|         |            | • >  
|         |            | • >=  
|         |            | • <  
|         |            | • <=  
|         |            | Strings (must be in upper case):                |
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• =</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• !=</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• IN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• NOT IN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• STARTSWITH</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• ENDSWITH</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• CONTAINS</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• DOES NOT CONTAIN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• INSTANCEOF</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

value | Object | Value on which to query (not case-sensitive).

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>A reference to the GlideQueryCondition that was added to the GlideRecord.</td>
</tr>
</tbody>
</table>

var rec = new GlideRecord('incident');
rec.addQuery('active', true);
rec.addQuery('sys_created_on', '>', '2010-01-19 04:05:00');
rec.query();
while (rec.next()) {
    rec.active = false;
    gs.print('Active incident ' + rec.number + ' closed');
    rec.update();
}

Using the IN operator.

var que = new GlideRecord('incident');
que.addQuery('number', 'IN', 'INC00001,INC00002');
que.query();
while (que.next()) {
    //do something....
}

Scoped equivalent

To use the `addQuery()` method in a scoped application, use the corresponding scoped method: Scoped GlideRecord - `addQuery(String name, String operator, Object value)`.

GlideRecord - `addValue(String field, Number value)`

Provides atomic add and subtract operations on a specified number field at the database level for the current GlideRecord object.

Typically, a GlideRecord object is written as one record in a database. Individual field values are stored as defined. For code that adds a value to a GlideRecord field, it simply saves the field to the database with the new value, rather than atomically incrementing it.

For example, when the following code is executed, the value of the `u_count` field in the database is 2.

```java
gs.print(now_now_GR.u_count); // "1"
now_GR.u_count += 1;
now_GR.update();
now_GR.get(now_now_GR.sys_id);
gs.print(now_now_GR.u_count); // "2"
```

If another user concurrently runs identical code, instead of the two operations each adding 1 to `u_count`, the net effect is that `u_count` only contains 2, with one operation's update actually being lost.

Conversely, the `addValue()` method performs the addition/subtraction in the database when the record is updated as an atomic operation. Two operations running concurrently each properly update the field.

```java
gs.print(now_now_GR.u_count); // "1"
now_GR.addValue("u_count", 1);
now_GR.update();
now_GR.get(now_GR); // The record must be reloaded from the database to observe the result
gs.print(now_now_GR.u_count); // "3", if executed concurrently with another user
```

⚠️ Note: The new value is not read back from the database unless explicitly done so.

Like `setValue()`, `addValue()` changes only take effect in the database after a subsequent call to `update()` or `insert()`. If `insert()` is called, the specified field is initialized with the `value` parameter passed into `addValue()`.

⚠️ Note: If `setValue()` is called for the specified field prior to calling `addValue()`, the `addValue()` method is not processed and an error message is logged.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>The name of the field in this GlideRecord to modify. If the associated field is not a numeric type, the operation is ignored.</td>
</tr>
<tr>
<td>value</td>
<td>Number</td>
<td>The amount to add to the value when the record is saved. To perform a subtraction operation, simply pass a negative value.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Shows a value being added.

```java
gs.print(now_GR.u_count); // "1"
now_GR.addValue("u_count", 1);
now_GR.update();
now_GR.get(now_GR.sys_id); // The record must be reloaded from the database to observe the result
gs.print(now_GR.u_count);
```

Output: 2

Shows a value being subtracted.

```java
gs.print(now_GR.u_count); // "4"
now_GR.addValue("u_count", -1);
now_GR.update();
now_GR.get(now_GR.sys_id); // The record must be reloaded from the database to observe the result
gs.print(now_GR.u_count);
```

Output: 3

**GlideRecord - applyEncodedQuery(String queryString)**

Sets the values of the specified encoded query terms and applies them to the current GlideRecord.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>queryString</td>
<td>String</td>
<td>Encoded query to apply to the current GlideRecord.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
function createAcl(table, role) {
  gs.print("Checking security on table " + table);
  var now_GR = new GlideRecord("sys_security_acl");
  now_GR.addQuery("name", table);
  now_GR.addQuery("operation", "read");
  now_GR.query();
  var encQuery = now_GR.getEncodedQuery();
  if (now_GR.next()) {
    // existing acl found so use it
    createAclRole(now_GR.sys_id.toString(), role);
    return;
  } else {
    now_GR.initialize();
    now_GR.applyEncodedQuery(encQuery);
    var acl = now_GR.insert();
    gs.print("Added read access control on " + table);
    createAclRole(acl, role);
  }
}
```

### GlideRecord - applyTemplate(String template)

Apply a template record from the Template table [sys_template] to the current record. If the specified template is not found, no action is taken.

**Note:** This method automatically instantiates a `now_GR.insert()` method if a template has the **Next Related Child Template** field filled. For information, see Create templates for related task records.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>template</td>
<td>String</td>
<td>Name of a template from the Templates [sys_template] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var rec1 = new GlideRecord("incident");
rec1.initialize();
rec1.applyTemplate("my_incident_template");
rec1.insert();
```

**GlideRecord - autoSysFields(Boolean e)**

Enables or disables the update to the fields sys_updated_by, sys_updated_on, sys_mod_count, sys_created_by, and sys_created_on. This is often used for manually updating field values on a record while leaving historical information unchanged.

ℹ️ **Note:** This is not available for scoped apps, starting with the Fuji release. See the Scoped GlideRecord API Reference for a list of what APIs are available for scoped apps.

⚠️ **CAUTION:** Use caution if you use this method. When you use this method the sys_mod_count field will not be incremented, and other sys_ fields will not be updated. This can break functionality including, but not limited to, the Activity Formatter, History Sets, Notifications, and Metrics.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>e</td>
<td>Boolean</td>
<td>If false disables updates to sys_updated_by, sys_updated_on, sys_mod_count, sys_created_by, and sys_created_on.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var inc = new GlideRecord('incident');

// Change all Open(1) incidents to Active(2)
inc.addQuery('state', 1);
inc.query();

while (inc.next()) {
    inc.autoSysFields(false);  // Do not update sys_updated_by, sys_updated_on,
                               // sys_mod_count, sys_created_by, and sys_created_on
    inc.setWorkflow(false);    // Do not run any other business rules
    inc.setValue('state', 2);
    inc.update();
}
```

**GlideRecord - canCreate()**

Determines if the access control rules (which includes the user's role) permit inserting new records in this table.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the user's roles permit creating of records in this table. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Creating permitted</td>
</tr>
<tr>
<td></td>
<td>• false: Creating is not permitted</td>
</tr>
</tbody>
</table>

This example shows whether records can be created on the benefit_plan table.
canCreateBenefitPlan : function() {
    var now_GR = new GlideRecord('benefit_plan');
    return now_GR.canCreate();
}

Scoped equivalent
To use the canCreate() method in a scoped application, use the corresponding scoped method: Scoped GlideRecord - canCreate().

GlideRecord - canDelete()
Determines if the access control rules (which includes the user's role) permit deletion of records in this table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean  | Flag that indicates whether the user's roles permit deleting of records in this table. Valid values:  
• true: Deleting permitted  
• false: Deleting is not permitted |

Example

```javascript
var att = new GlideRecord('sys_attachment');
att.get('${sys_attachment.sys_id}');
var sm = GlideSecurityManager.get();
var checkMe = 'record/sys_attachment/delete';
var canDelete = sm.hasRightsTo(checkMe, att);
gs.log('canDelete: ' + canDelete);
```

Scoped equivalent
To use the canDelete() method in a scoped application, use the corresponding scoped method: Scoped GlideRecord - canDelete().
**GlideRecord - canRead()**

Determines if the access control rules (which includes the user's role) permit reading this table.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the user's roles permit reading of records in this table. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Reading permitted</td>
</tr>
<tr>
<td></td>
<td>• false: Reading is not permitted</td>
</tr>
</tbody>
</table>

This example shows whether records can be read from the benefit_plan table.

```javascript
canReadBenefitPlan: function() {
    var now_GR = new GlideRecord('benefit_plan');
    return now_GR.canRead();
}
```

**Scoped equivalent**

To use the `canRead()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - canRead()**.

**GlideRecord - canWrite()**

Determines if the access control rules (which includes the user's role) permit updates to records in this table.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates whether the user’s roles permit writing of records in this table. Valid values:  
• true: Writing permitted  
• false: Writing is not permitted |

This example shows whether records can be written to the benefit_plan table.

canWriteBenefitPlan : function() {
    var now_GR = new GlideRecord('benefit_plan');
    return now_GR.canWrite();
}

 Scoped equivalent

To use the `canWrite()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - canWrite()`.

GlideRecord - changes()

Determines whether any of the fields in the record have changed.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates whether there are changes in the specified record. Possible values:  
• true: Fields in the specified record have changed.  
• false: No fields have changed. |

This example shows how to check if there are changes in an incident record.
var now_GR = new GlideRecord("incident");
now_GR.query();
now_GR.next();
if (now_GR.changes()) {
    gs.print("The incident record reported changes right after being read");
} else {
    gs.print("The incident record has not changed");
}

**Scoped equivalent**
To implement this functionality in a scoped application, add code similar to the following:

```javascript
var now_GR = new GlideRecord("incident");
now_GR.get("965c9e5347c12200e0ef563dbb9a7156");
now_GR.short_description = "test";
var elements = now_GR.getElements();
var hasChanged = false;
for(var i=0; i < elements.length;i++){
    var element = elements[i];
    hasChanged = hasChanged || element.changes();
    gs.info(element.getName() + " : " + element.changes());
}
gs.info(hasChanged);
```

**GlideRecord - deleteMultiple()**
Deletes multiple records according to the current "where" clause.

This method does not delete attachments.

Dot-walking is not supported for this method. When using the `deleteMultiple()` function on referenced tables, all the records in the table are deleted. Also, when using `deleteRecord()` to cascade delete, prior calls to `setWorkflow()` on the same GlideRecord object are ignored.

Do not use `deleteMultiple()` on tables with currency fields. Always delete each record individually. Also, do not use this method with the `chooseWindow()` or `setLimit()` methods when working with large tables.

<p>| Parameters |
|---|---|---|
| Name | Type | Description |
| None | | |</p>
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the record was successfully deleted. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Record was deleted.</td>
</tr>
<tr>
<td></td>
<td>• false: No record was found to delete.</td>
</tr>
</tbody>
</table>

This example shows how to delete a record from the Incident table.
var rec = new GlideRecord('incident');
rec.addQuery('active',false);
rec.query();
while (rec.next()) {
    gs.print('Inactive incident ' + rec.number + ' deleted');
    rec.deleteRecord();
}

Scoped equivalent

To use the `deleteRecord()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - deleteRecord()`.

**GlideRecord - find(String columnName, String value)**

Returns true if any record has a matching value in the specified column. If found, it also moves to the first record that matches, essentially executing `next()` until the record is returned.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnName</td>
<td>String</td>
<td>Field name to search.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Value to check for in the specified field.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether any record within the current table has a matching value in the specified field. Possible values:</td>
</tr>
<tr>
<td></td>
<td>- true: Matching field.</td>
</tr>
<tr>
<td></td>
<td>- false: No matching field.</td>
</tr>
</tbody>
</table>

This example shows how to find a record in the Incident table with "Critical" in the short description field.

```javascript
var now_GR = new GlideRecord("incident");
now_GR.query();
var shortDescription = "Critical";
if (now_GR.find("short_description", shortDescription)) {
    gs.print("An incident with the specified field value was found");
}
```
var recordID = now_GR.getValue("sys_id");
gs.print("Found in the following record: " + recordID);
} else {
    gs.print("An incident with the specified field value was not found");
}

Output
An incident with the specified field value was found
Found in the following record: 552c48888c033300964f4932b03eb092

GlideRecord - get(Object name, Object value)

Returns the specified record in the current GlideRecord object.

This method accepts either one or two parameters. If only a single parameter is passed in, the method assumes that it is the sys_id of the desired record. If not found, it then tries to match the value against the display value. If two parameters are passed in, the first is the name of the column within the GlideRecord to search. The second is the value to search for.

If multiple records are found, use `next()` to access the additional records.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Object</td>
<td>Optional. Name of the instantiated GlideRecord column to search for the specified value parameter. If only a single parameter is passed in, the method assumes that this parameter is sys_id.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>Value to match.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Indicates whether the requested record was located. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Record was found</td>
</tr>
<tr>
<td></td>
<td>• false: Record was not found</td>
</tr>
</tbody>
</table>

This example gets an incident record by passing in the sys_id.
```javascript
var grIncident = new GlideRecord('incident');
var returnValue = grIncident.get('99ebb4156fa831005be8883e6b3ee4b9');
gs.info(returnValue); // logs true or false
gs.info(grIncident.number); // logs Incident Number
```

This example gets an incident record by passing in the column in the record to search and the value to search for.

```javascript
var grIncident = new GlideRecord('incident');
var returnValue = grIncident.get('caller_id.name','Sylivia Wayland');
gs.info(returnValue); // logs true or false
gs.info(grIncident.number); // logs Incident Number
```

**Scoped equivalent**

To use the `get()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - get(Object name, Object value)**.

**GlideRecord - getAttribute(String fieldName)**

Returns the dictionary attributes on the specified field.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Field name for which to return the dictionary attributes</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Dictionary attributes</td>
</tr>
</tbody>
</table>

This example shows how to return the dictionary attributes for “tree_picker”.

```javascript
function doit() {
  var now_GR = new GlideRecord('sys_user');
  now_GR.query("user_name","admin");
  if (now_GR.next()) {
    gs.print("we got one");
    gs.print(now_GR.location.getAttribute("tree_picker"));
  }
}
```
Scoped equivalent

To use the `getAttribute()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - getAttribute(String fieldName).**

GlideRecord - `getClassDisplayValue()`

Returns the table's label.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

This example prints the label of the passed in table.

```java
// Display the incident table label
var now_GR = new GlideRecord("incident");
var value = now_GR.getClassDisplayValue();
gs.info("The table label is " + value + ";");
```

Output:

The table label is Incident.

Scoped equivalent

To use the `getClassDisplayValue()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - getClassDisplayValue().**

GlideRecord - `getDisplayValue()`

Retrieves the display value for the current record.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
<tr>
<td>Returns</td>
</tr>
<tr>
<td>---------</td>
</tr>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

This example writes the display value of a specified incident record into the log.

```javascript
var now_GR = new GlideRecord('incident');
now_GR.get('sys_id','<sys_id>');
gs.info(now_GR.getDisplayValue());
```

Output:

```
INC0000050
```

**Scoped equivalent**

To use the `getDisplayValue()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - getDisplayValue()`.

**GlideRecord - getED()**

Returns the element's descriptor.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to retrieve the name field for an incident GlideRecord.

```javascript
grInc = new GlideRecord('incident');
grInc.getActiveQuery();
grInc.query();
if (grInc.next())
    gs.info("Table Descriptor is - " + grInc.getED().getName());
```

Output:

```
"Table Descriptor is - " + grInc.getED().getName()
```
**Scoped equivalent**

To use the `getED()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - getED()**.

**GlideRecord - getElement(String fieldName)**

Retrieves the GlideElement for a specified field.

The value returned by this method is a complete GlideElement object. The results are the equivalent of dot-walking a field value. For example, `now_GR.getElement('short_description')` provides the same result as `nowGR.short_description`.

In most cases, do not use dot-walking to get values from a record. Dot-walking retrieves the entire object instead of the field value. Retrieving the object uses much more storage and might cause undesirable results when used in arrays or in Service Portal.

Instead of retrieving the entire object, you can use one of the following methods to copy the field values:

- `getValue()`
- `getDisplayValue()`

If dot-walking through a GlideElement object is necessary, use the `toString()` method to retrieve values. For example, you might need the current caller's manager sys_id to set another reference field. The following example shows how to get the string value instead of the entire object:

```java
var mgr = current.caller_id.manager.toString();
```

See also: **GlideElement - toString()**.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Column name for which to return the GlideElement object.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideElement</td>
<td>The GlideElement for the specified column of the current record. Each object describes a field in the current GlideRecord.</td>
</tr>
</tbody>
</table>

This example shows how to obtain the GlideElement object for a passed in table and compare them with the expected system metadata values.

```javascript
function compareElement(comment, table, element, /*{}*/ expected) {
    var now_GR = new GlideRecord(table);
    var el = now_GR.getElement(element);
    for (var n in expected) {
        assertEquals(comment + "::" + table + "." + element, expected[n], el.sys_meta[n]);
    }
}
```

Scoped equivalent

To use the `getElement()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - getElement(String fieldName)**.

**GlideRecord - getEncodedQuery()**

Retrieves the query condition of the current result set as an encoded query string.

For details, see **Encoded query strings**.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to obtain the current encoded query to use later to create a read ACL role.
function createAcl(table, role) {
    gs.print("Checking security on table "+table);
    var now_GR = new GlideRecord("sys_security_acl");
    now_GR.addQuery("name", table);
    now_GR.addQuery("operation", "read");
    now_GR.query();
    var encQuery = now_GR.getEncodedQuery();
    if (now_GR.next()) {
        // existing acl found so use it
        createAclRole(now_GR.sys_id.toString(), role);
        return;
    } else {
        now_GR.initialize();
        now_GR.applyEncodedQuery(encQuery);
        var acl = now_GR.insert();
        gs.print("   Added read access control on " + table);
        createAclRole(acl, role);
    }
}

Scoped equivalent

To use the getEncodedQuery() method in a scoped application, use the corresponding scoped method: Scoped GlideRecord - getEncodedQuery().

GlideRecord - getEscapedDisplayValue()

Retrieves the field value for the display field of the current record and adds escape characters for use in Jelly scripts.

⚠️ Note: For this method to work, a display value must have been set on the associated table. For information on how to do this, see Select a field as the table display value.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Escaped value of the current table's display field.</td>
</tr>
</tbody>
</table>

This example shows how to obtain the user_name escaped display value from the User [sys_user] table.

```javascript
var userName = "Michael J'ones";
var now_GR = new GlideRecord("sys_user");
if (now_GR.get("user_name", userName)) {
    gs.print("Deleting existing user=" + userName);
    now_GR.deleteRecord();
}
now_GR.initialize();

var name = userName.split(" ", 2);
var firstName = name[0];
var lastName = name[1];
now_GR.setValue("user_name", userName);
gs.print("Name: " + now_GR.getValue("user_name"));
now_GR.setValue("first_name", firstName);
now_GR.setValue("last_name", lastName);
var escapeValue = now_GR.getEscapedDisplayValue();
gs.print("Escaped name: " + escapeValue);
```

Output:

- Name: Michael J'ones
- Escaped name: Michael J\'ones

**GlideRecord - getFields()**

Retrieves a Java ArrayList of fields in the current record.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Java ArrayList</td>
<td>Fields in the current record</td>
</tr>
</tbody>
</table>

// This can be run in "Scripts - Background" for demonstration purposes

// Get a single incident record
var grINC = new GlideRecord('incident');
grINC.query();
grINC.next();
gs.print('Using ' + grINC.getValue('number'));
gs.print('');

// getFields() returns a Java ArrayList
var fields = grINC.getFields();

// Enumerate GlideElements in the GlideRecord object that have values
gs.print('Enumerating over all fields with values:');
for (var i = 0; i < fields.size(); i++) {
    var glideElement = fields.get(i);
    if (glideElement.hasValue()) {
        gs.print(' ' + glideElement.getName() + '\t' + glideElement);
    }
}
gs.print('');

// Get a specific GlideElement: number
gs.print('Getting the number field:');
for (var i = 0; i < fields.size(); i++) {
    var glideElement = fields.get(i);
    if (glideElement.hasValue() && glideElement.getName() == 'number') {
        gs.print(' ' + glideElement.getName() + '\t' + glideElement);
    }
}

GlideRecord - getLabel()
Retrieves the field's label.
This example shows how to retrieve a label of a question field in the Requested Item table and print the label and its display name.

```javascript
template.print("Summary of Requested items:\n");
var now_GR = new GlideRecord("sc_req_item");
now_GR.addQuery("request", current.sysapproval);
now_GR.query();
while(now_GR.next()) {
    var nicePrice = now_GR.price.toString();
    if (nicePrice != '') {
        nicePrice = parseFloat(nicePrice);
        nicePrice = nicePrice.toFixed(2);
    }
    template.print(now_GR.number + ":  " + now_GR.quantity + " X " +
    now_GR.cat_item.getDisplayValue()
    + " at $" + nicePrice + " each \n");
    template.print("    Options:\n");
    for (key in now_GR.variables) {
        var now_V = now_GR.variables[key];
        if(now_V.getGlideObject().getQuestion().getLabel() != '') {
            template.space(4);
            template.print('     ' + now_V.getGlideObject().getQuestion().getLabel() + " = " +
            now_V.getDisplayValue() + "\n");
        }
    }
}
```

**Scoped equivalent**

To use the `getLabel()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - getLabel()`.
GlideRecord - getLink(Boolean noStack)

Retrieves the link for the current record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>noStack</td>
<td>Boolean</td>
<td>Flag that indicates whether to append the generated link to the end of the URL. For example: &amp;sysparm_stack=[tablename]_list.do?sysparm_query=active=true. Valid values: • true: Append link. • false: Do not append link. Default: false</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>URL of the current record.</td>
</tr>
</tbody>
</table>

This example checks for attachments and adds the link if any are found.

```javascript
var attachment_link = ''; 
var rec = new GlideRecord('sc_req_item'); 
rec.addQuery('sys_id', current.request_item); 
rec.query(); 
if(rec.next()){ 
  if(rec.hasAttachments()){ 
    attachment_link = gs.getProperty('glide.servlet.uri') + rec.getLink(); 
  } 
}
```

Scoped equivalent

To use the getLink() method in a scoped application, use the corresponding scoped method: Scoped GlideRecord - getLink(Boolean noStack).

GlideRecord - getLocation()

Retrieves the row number of the current record within the table.
This example shows how to check if a record within the Incident table is not retrieved properly by comparing the record count to the record location number.

```javascript
var now_GR = new GlideRecord("incident");
now_GR.addQuery("priority", "4");
now_GR.query();
for (x=0; x < 4; x++) {
    now_GR.next();
    gs.print("Location value: " + now_GR.getLocation());
}
```

Output:

```
Location value: 0
Location value: 1
Location value: 2
Location value: 3
```

**GlideRecord - getPlural()**

Retrieves the plural label of the GlideRecord table.

For example, if the table name is "Change Request," this method returns "Change Requests."
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The plural label of the GlideRecord's table.</td>
</tr>
</tbody>
</table>

This example shows checks the return values for `getLabel()` and `getPlural()` for the Incident table.

```javascript
var now_GR = new GlideRecord('incident');
gs.print(now_GR.getLabel());
if (now_GR.getLabel() != 'Incident')
    throw "GlideRecord.getLabel() returned unexpected value for table 'incident': " +
    now_GR.getLabel();

gs.print(now_GR.getPlural());
if (now_GR.getPlural() != 'Incidents')
    throw "GlideRecord.getPlural() returned unexpected value for table 'incident': " +
    now_GR.getPlural();
"success";
```

### Scoped equivalent

To use the `getPlural()` method in a scoped application, use the scoped `GlideRecord.getED()` method to obtain the field’s descriptor, and then use the scoped `GlideElementDescriptor.getPlural()` method.

#### GlideRecord - getRecordClassName()

Retrieves the class (table) name for the current record.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Class or table name</td>
</tr>
</tbody>
</table>

```javascript
function TaskAssignmentFilter() {
    var classname = current.getRecordClassName();
}
var filter = "type=null";
if (classname == "incident" && current.category == "database") {
    filter = GetGroupFilter("database");
}
else {
    // append exclusion for 'catalog' to the filter
    var cat = new GlideRecord("sys_user_group_type");
cat.addQuery("name", "catalog");
cat.query();
if (cat.next()) {
    filter += "^ORtype!=" + cat.sys_id;
}
}
gs.log("TaskAssignmentFilter: " + filter);
return filter;

Scoped equivalent

To use the getRecordClassName() method in a scoped application, use the corresponding scoped method: Scoped GlideRecord - getRecordClassName().

GlideRecord - getRelatedLists()
Retrieves a list of names and display values of related lists associated with the current GlideRecord.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HashMap</td>
<td>Hash map with names and display values of related lists.</td>
</tr>
</tbody>
</table>

This example shows how to obtain the list of names and display values of related lists associated with the current GlideRecord, store them in an array, and then print their values.

```javascript
var now_GR = new GlideRecord('incident');
var c = now_GR.getRelatedLists().values().toArray();
```
var numElements = c.length;
for( var i = 0; i < numElements; ++i){
gs.print(i+": "+c[i]);
}

GlideRecord - getRelatedTables()
Retrieves a list of names and display values of tables that are referred to by the
current record.
Parameters
Name

Type

Description

None
Returns
Type

Description

HashMap

Hash map with names and display values of related tables.

This example shows how to obtain the list of names and display values of tables
related to the current GlideRecord, store them in an array, and then print their
values.
var now_GR = new GlideRecord('incident');
var c = now_GR.getRelatedTables().values().toArray();
var numElements = c.length;
for( var i = 0; i < numElements; ++i){
gs.print(i+": "+c[i]);
}

GlideRecord - getRowCount()
Retrieves the number of rows (records) in the current GlideRecord object.
Note: This method should not be used in a production environment as it
creates a heavy load on the system. Instead, use GlideAggregate - Global.
Parameters
Name

Type

Description

None
2495

This example shows how to check if there are any records in the Incident table:

```javascript
function onSubmit() {
    var g_list = GlideRecord("incident");
    if (g_list.getRowCount() == 0) {
        alert("You must add at least one incident");
        return false;
    } else
    return true;
}
```

### Scoped equivalent
To use the `getRowCount()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - `getRowCount()`**.

### GlideRecord - `getRowNumber()`
Retrieves the row number set by `saveLocation()` or `setLocation()`.

To get the current row number, use `getLocation()`.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Saved row number.</td>
</tr>
</tbody>
</table>

This example shows how to save a row location in the Users table and then obtain that row number:

```javascript
var now_GR = new GlideRecord('sys_user');
now_GR.addQuery();
now_GR.query();
```
now_GR.saveLocation(5);
var savedRow = now_GR.getRowNumber();
gs.print("Saved row: " + savedRow);

Output:
Saved row: 5

**GlideRecord - getTableName()**
Retrieves the table name associated with this GlideRecord.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A table name</td>
</tr>
</tbody>
</table>

This example shows how to write the current table name in the system log.

```javascript
gs.log('Table: ' + current.getTableName());
gs.log('Parent: ' + current.parent.sys_id);
var item = new GlideRecord('sc_req_item');
item.addQuery('sys_id', current.parent.sys_id);
item.query();
if(item.next()){
    for(var variable in item.variable_pool) {
        gs.log(variable);
        var answer = eval("item.variable_pool." + variable + ".getDisplayValue()");
        gs.log(answer);
    }
}
```

**Scoped equivalent**

To use the `getTableName()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - getTableName()**.
GlideRecord - getValue(String fieldName)
Retrieves the string value of a specified field.

Note: If the Column Level Encryption Enterprise plugin is enabled and the instance has access to the key, this method returns clear text values from encrypted fields. If the instance does not have access to the key, this method returns the encrypted value. For more information, see Column Level Encryption Enterprise.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of a field for which to retrieve its value.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value of the specified element. Returns null if the field is empty or the field does not exist.</td>
</tr>
</tbody>
</table>

Note: Boolean values return as "0" and "1" string values instead of false and true.

This example uses the getValue() method to obtain field values in two GlideRecords that are being compared.

```javascript
function() {
  var jobExists = true;
  var jobGr;
  while(jobExists){
    jobGr = new GlideRecord("sys_trigger");
    jobExists = jobGr.get("name", "BaselineAPI: Create Baseline Job");
  }
  var baselineGr = new GlideRecord('pm_project_baseline');
  baselineGr.get('baseline_name', 'Test Project Baseline');
  baselineGr.query();
  Assert.assertEquals(true, baselineGr.next());
  var projectGr = new GlideRecord('pm_project');
  projectGr.get(this._project);
  Assert.assertEquals(projectGr.getValue('cost'), baselineGr.getValue('cost'));
  Assert.assertEquals(projectGr.getValue('capex_cost'), baselineGr.getValue('capex_cost'));
```
Scoped equivalent

To use the `getValue()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - getValue(String name)`.

**GlideRecord - GlideRecord(String tableName)**

Creates an instance of the GlideRecord class for the specified table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Table to use.</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
```

**GlideRecord - hasAttachments()**

Determines if the current GlideRecord has any attachments.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the current record has attachments, false otherwise.</td>
</tr>
</tbody>
</table>

This example checks for attachments and creates a link if there are any.

```javascript
var attachment_link = '';
var rec = new GlideRecord('sc_req_item');
```
rec.addQuery('sys_id', current.request_item);
rec.query();
if(rec.next()){
    if(rec.hasAttachments()){
        attachment_link = gs.getProperty('glide.servlet.uri') + rec.getLink();
    }
}

**GlideRecord - hasNext()**

Determines if there are any more records in the GlideRecord.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if there are more records in the query set, otherwise false.</td>
</tr>
</tbody>
</table>

This example shows how to call different functions based on whether there are additional records in the current GlideRecord.

```java
if (now_GR.hasNext()) {
    dothis(); // found it, do it
} else {
    dothat(); // didn't find it
}
```

**Scoped equivalent**

To use the `hasNext()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - hasNext()**.

**GlideRecord - initialize()**

Creates an empty record within the current GlideRecord that is suitable for population before an insert.
This example initializes a new record in the to_do table, creates a record, and then inserts it into the table.

```javascript
var now_GR = new GlideRecord('to_do');
now_GR.initialize();
now_GR.name = 'first to do item';
now_GR.description = 'learn about GlideRecord';
now_GR.insert();
```

**Scoped equivalent**

To use the `initialize()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - initialize()`.

**GlideRecord - insert()**

Inserts a new record with the field values that have been set for the current record.

This example creates a new record in the to_do table, sets values for some record fields, and then inserts the record into the table.
var now_GR = new GlideRecord('to_do');
now_GR.initialize();
now_GR.name = 'first to do item';
now_GR.description = 'learn about GlideRecord';
now_GR.insert();

**Scoped equivalent**

To use the `insert()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - insert()**.

**GlideRecord - insertWithReferences()**

Inserts a new record and also inserts or updates any related records with the provided information.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

If a reference value is not specified (as below), then a new user record is created with the provided first_name and last_name, and the caller_id value is set to this newly created sys_user record. The result is a new sys_user record with the provided first_name and last_name and a new incident record with the provided short_description and caller_id.

```javascript
var inc = new GlideRecord('incident');
inc.initialize();
inc.short_description = 'New incident 1';
inc.caller_id.first_name = 'John';
inc.caller_id.last_name = 'Doe';
inc.insertWithReferences();
```

If a caller_id value is specified, then that caller_id is updated with the provided first_name and last_name. The result is a newly created incident record with values set for short_description and caller_id.
```javascript
var inc = new GlideRecord('incident');
inc.initialize();
inc.short_description = 'New incident 1';
inc.caller_id.setDisplayValue('David Loo');
inc.caller_id.first_name = 'John';
inc.caller_id.last_name = 'Doe';
inc.insertWithReferences();
```

### GlideRecord - instanceOf(String className)
Checks a table for the type/class of table.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>className</td>
<td>String</td>
<td>Name of a type or class of record.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if table is an instance of the specified class.</td>
</tr>
</tbody>
</table>

This example checks if the passed in group/user is of the sys_user table/class type.

```javascript
function(groupOrUser, label, grantedBy) {
  var labelCheck;
  var labelRecord;
  if (typeof label === "string") {
    labelRecord = new GlideRecord('label');
    labelRecord.addQuery('name', label);
    labelRecord.query();
    labelRecord.next();
  } else {
    labelRecord = label;
  }
  if (groupOrUser.instanceOf('sys_user')) {
    labelCheck = new GlideRecord('label_user_m2m');
    labelCheck.addQuery('user', groupOrUser.sys_id);
  } else {
    labelCheck = new GlideRecord('label_group_m2m');
    labelCheck.addQuery('group', groupOrUser.sys_id);
  }
}
```
```javascript
} 
labelCheck.addQuery('label', labelRecord.sys_id);
if (grantedBy !== "undefined") {
    labelCheck.addQuery('granted_by', grantedBy.sys_id);
}
labelCheck.query();
return labelCheck.hasNext();

GlideRecord - isNewRecord()
Determines whether the current record has been inserted into the database.

This method returns true only if the `newRecord()` method has been called. This method is useful for scripted ACL, and in the condition of UI actions, but should not be used in background scripts.

⚠️ **Note:** This method returns true for any new record during a business rule, or if the `newRecord()` method is used to initialize a record with default values and a unique ID (sys_id). In all other cases, it returns false.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates whether the current record is new (has not been inserted into the database.) Possible values:  
- true: Record is new.  
- false: Record is not new. |

This example checks if the new record has been inserted into the sys_user table.

```javascript
var now_GR = new GlideRecord("sys_user");
now_GR.newRecord();
now_GR.setValue("user_name", "John Smith");
gs.print("Is this a new record: "+ now_GR.isNewRecord());

var now_GR2 = new GlideRecord("sys_user");
```
GlideRecord - isValid()

Determine if the current GlideRecord table exists.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the table exists (valid), otherwise false.</td>
</tr>
</tbody>
</table>

This example checks if the Incident table exists.

```java
var testTable = new GlideRecord('incident');
gs.print(testTable.isValid());
```

Scoped equivalent

To use the isValid() method in a scoped application, use the corresponding scoped method: Scoped GlideRecord - isValid().

GlideRecord - isValidField(String fieldName)

Determine if the specified field is defined in the current GlideRecord table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of a field to check.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the field is defined in the table, otherwise false.</td>
</tr>
</tbody>
</table>

This example checks if the `sys_class_name` field exists in the `cmds_software_instance` table.

```javascript
var gobj = new GlideRecord('sys_db_object');
gobj.addQuery('name','cmdb_software_instance');
gobj.query();
if (!gobj.next()) {
  var si = new GlideRecord('cmdb_software_instance');
  si.query();
  var count = 0;
  while (si.next()) {
    if (!si.isValidField('sys_class_name')) {
      var ci = new GlideRecord('cmdb_ci');
      ci.name = si.name;
      ci.setNewGuidValue(si.sys_id);
      ci.sys_class_name = 'cmdb_software_instance';
      ci.insert();
      count++;
    }
  }
}
```

Scoped equivalent

To use the `isValidField()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - isValidField(String columnName)**.

**GlideRecord - isValidRecord()**

Determines if the current record is valid.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag indicating whether the current record is valid.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Record is valid.</td>
</tr>
<tr>
<td></td>
<td>• false: Past the end of the record set.</td>
</tr>
</tbody>
</table>

This example checks if the record identifier by the passed in sys_id is a valid record in the idea table.

```javascript
function(sysId) {
    this.log('Inside acceptIdea sysId = ' + sysId);
    var now_GR = new GlideRecord('idea');
    now_GR.get(sysId);
    this.log('now_GR.isValidRecord() = ' + now_GR.isValidRecord());
    if(now_GR.isValidRecord()) {
        now_GR.setValue('state', 2);
        this.log('Updating gliderecord');
        this.log('gliderecord table name' + now_GR.getTableName());
        now_GR.update();
    }
}
```

**Scoped equivalent**

To use the `isValidRecord()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - isValidRecord()`.

**GlideRecord - newRecord()**

Creates a GlideRecord, sets the default values for the fields, and assigns a unique ID to the record.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example checks if the new record has been inserted into the sys_user table.

```javascript
var now_GR = new GlideRecord("sys_user");
now_GR.newRecord();
now_GR.setValue("user_name", "John Smith");
gs.print("Is this a new record: " + now_GR.isNewRecord());

var now_GR2 = new GlideRecord("sys_user");
now_GR2.addQuery("user_name", "Abel Tutor");
now_GR2.query();
now_GR2.next();
gs.print("Is this a new record: " + now_GR2.isNewRecord());
```

**Scoped equivalent**

To use the `newRecord()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - newRecord()`.

**GlideRecord - next()**

Moves to the next record in the GlideRecord.

Use this method to iterate through the records returned by a GlideRecord query.

⚠️ **Note:** This method fails if there is a field in the table called "next". If that is the case, use the method `GlideRecord - _next()`.

⚠️ **Note:** The `if(myObj.next())` construct only processes the first record returned.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates if there is a &quot;next&quot; record in the GlideRecord. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Move to the next record was successful.</td>
</tr>
<tr>
<td></td>
<td>• false: No more records in the result set.</td>
</tr>
</tbody>
</table>

This example shows how to iterate through the Incident table using the `next()` method.

```javascript
var rec = new GlideRecord('incident');
rec.query();
while (rec.next()) {
    gs.print(rec.number + ' exists');
}
```

Scoped equivalent

To use the `next()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - next()`.

GlideRecord - `_next()`

Moves to the next record in the GlideRecord. Provides the same functionality as `next()`, intended to be used in cases where the GlideRecord has a column named `next`.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if there are more records in the query set.</td>
</tr>
</tbody>
</table>

```javascript
var rec = new GlideRecord('sys_template');
rec.query();
while (rec._next()) {
    ...
}
```
Scoped equivalent

To use the `_next()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - _next().**

GlideRecord - operation()

Determines if an operation is insert, update, or delete.

Knowing the operation enables using `current.operation()` to make a generic business rule which can handle each operation uniquely.

For information on using the global variable `current`, refer to **Global variables in business rules.**

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>String</td>
<td>The current operation. Possible values: • delete • insert • update</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to use this method in a business rule. The `operation()` method detects which operation triggered an event and performs a different action depending for update and insert operations.

```java
if(current.operation() == "update") {
    current.updates ++; }
if(current.operation() == "insert") {
    current.updates = 0; }
```

This example shows how to use the `operation()` method to pass the operation value into the `startFlow()` method.
function createNewTransferOrder() {
    var toGr = new GlideRecord("alm_transfer_order");
    toGr.initialize();
    // From Stockroom - Southern California Warehouse
    toGr.setValue('from_stockroom', fromStockroomSysId);
    // To Stockroom - San Diego North - Pickup/Dropoff
    toGr.setValue('to_stockroom', toStockroomSysId);
    var transferOrder = toGr.insert();

    if(toGr.get(transferOrder)) {
        // Start Transfer Order Workflow
        var wf = new Workflow();
        var context = wf.startFlow(toWorkflowSysId, toGr, toGr.operation(), {});
        createNewTransferOrderLine(transferOrder);
    }
}

Scoped equivalent

To use the operation() method in a scoped application, use the corresponding scoped method: Scoped GlideRecord - operation().

GlideRecord - orderBy(String fieldName)

Specifies a field name to use to order the query set. To order by multiple fields, call this method multiple times with different field values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Field on which to order the query set.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to order the query set by “order” and then by “number”.

function UpdateProjectWBS(project) {
    var count = 0;
    var child = new GlideRecord('pm_project_task');
    child.addQuery('parent', project.sys_id);
child.orderBy('order');
child.orderBy('number');
child.query();
var len = child.getRowCount().toString().length;
var seq = 0;
while (child.next()) {
    count += UpdateProjectTaskWBS(child, 1, ++seq, len, '');
}
gs.addInfoMessage(count + ' Project Tasks updated');

Scoped equivalent

To use the `orderBy()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - orderBy(String name)`.  

**GlideRecord - orderByDesc(String, fieldName)**

Specifies the field to use to order the query set in descending order.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of field to use to order the query results in descending order.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to order the query set in ascending or descending order.

```javascript
function(fiscalType, orderByDesc) {
    var now_GR = new GlideRecord('fiscal_period');
    now_GR.addQuery('fiscal_type', fiscalType);
    if (orderByDesc) {
        now_GR.orderByDesc('fiscal_start_date_time');
    } else {
        now_GR.orderBy('fiscal_start_date_time');
    }
    now_GR.setLimit(1);
}
```
Scoped equivalent

To use the `orderByDesc()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - orderByDesc(String name)`.

GladeRecord - query(String field, String value)

Runs a query against the table based on the filters specified by query methods such as `addQuery()` and `addEncodedQuery()`.

This method queries the GlideRecord table as well as any references of the table. For more information, see Querying tables in script.

⚠️ Note: This method fails if there is a field in the table called "query". If that is the case, use the method `_query()`. To run queries in a domain-separated instance, use the method queryNoDomain().

See also:
- GlideAggregate - Global
- GlideQuery - Scoped, Global
- GlideQueryCondition - Global

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Optional - must also specify value parameter. Name of the field to search for the value specified in the value parameter.</td>
</tr>
</tbody>
</table>

⚠️ Note: This method is typically run without arguments, but you can specify a name-value pair to filter records containing the specified values. If the parameters are specified, the "name=value" condition is added to the query.
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>Optional - must also specify field parameter. Value to search for in the specified field parameter.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to scan the System Dictionary [sys_dictionary] for tables with a query field.

```javascript
var tableArr = [];

var now_GR = new GlideRecord('sys_dictionary');
now_GR.addQuery('element', 'query');
now_GR.setLimit(6);

now_GR.query();

while(now_GR.next()){  
    tableArr.push(now_GR.name.getValue());
}

gs.info('The following tables have a field column called "query":');

for (i = 0; i < tableArr.length; i++) {
    gs.info(tableArr[i]);
}

Output:

The following tables have a field column called "query":
  cmdb_convert_bulk_services
  cmdb_multisource_query_status
  cmdb_qb_result_base
  cmdb_qb_table_mapping
  discovery_probes_cim_query
  kb_feedback
```
Scoped equivalent

To use the `query()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - query(String field, String value)`.

GlideRecord - `_query(String field, String value)`

Runs a query against the table based on the filters specified by query methods such as `addQuery()` and `addEncodedQuery()`. This method is intended to be used on tables in which there is a column named "query", which might cause errors running the `query()` method.

This method queries the GlideRecord table as well as any references of the table. For more information, see Querying tables in script.

See also:
- GlideAggregate - Global
- GlideQuery - Scoped, Global
- GlideQueryCondition - Global

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Optional - must also specify value parameter. Name of the field to search for the value specified in the value parameter.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Optional - must also specify field parameter. Value to search for in the specified field parameter.</td>
</tr>
</tbody>
</table>

Note: This method is typically run without arguments, but you can specify a name-value pair to filter records containing the specified values. If the parameters are specified, the "name=value" condition is added to the query.

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
The following example shows how query the Knowledge Feedback [kb_feedback] table and list KB articles with comments that include Excel.

```javascript
var rec = new GlideRecord('kb_feedback');
rec.addQuery('comments', 'CONTAINS', 'Excel');
rec._query();
while (rec.next()) {
    gs.info(rec.getDisplayValue('article') + " comment: " + rec.getValue('comments'));
}
```

Output:

```
KB0000005 comment:
    Can you please add the version of Excel this applies to? All?

KB0000005 comment:
    Does this work for all Excel versions? OSX and Windows alike?
```

**Scoped equivalent**

To use the `_query()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - _query(String field, String value)**.

**GlideRecord - queryNoDomain(String field, String value)**

Used in domain-separated instances. Similar to `query()`, runs the query against the table based on the filters specified by `addQuery()` and `addEncodedQuery()`, but ignores domains.

This method queries the GlideRecord table as well as any references of the table. For more information, see [Querying tables in script](#).

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Optional - must also specify value parameter. Name of the field to search for the value specified in the value parameter. <strong>Note:</strong> This method is typically run without arguments, but you can specify a name-value pair to filter records containing the specified values. If the parameters are specified, the &quot;name=value&quot; condition is added to the query.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>Optional - must also specify field parameter. Value to search for in the specified field parameter.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to query the incident table for all domains.

```javascript
var rec = new GlideRecord('incident');
rec.queryNoDomain();
while (rec.next()) {
  gs.print(rec.number + ' exists');
}
```

**GlideRecord - restoreLocation()**

Sets the current record to be the record that was saved with `saveLocation()`. If `saveLocation()` has not been called, the current record is set to the first record of the GlideRecord.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how save the current record location, move to the next record, and then return back to the saved location.

```javascript
function() {
  var now_GR = new GlideRecord("incident");
```
now_GR.query();
now_GR.next();
var firstID = now_GR.getValue("sys_id");
now_GR.next();
var restoreID = now_GR.getValue("sys_id");
now_GR.saveLocation();
now_GR.next();
var lastID = now_GR.getValue("sys_id");
now_GR.restoreLocation();
now_GR.next();
var thisID = now_GR.getValue("sys_id");
var progress = "first id=" + firstID
+ "\n\t last id=" + lastID
+ "\n\t saved id=" + restoreID
+ "\n\t restored id=" + thisID;
gs.print("Progress:\n\t" + progress);
}

**GlideRecord - saveLocation()**

Saves the current row number so you can return to this location using the `restoreLocation()` method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how save the current record location, move to the next record, and then return back to the saved location.

```javascript
function() {
  var now_GR = new GlideRecord("incident");
  now_GR.query();
  now_GR.next();
  var firstID = now_GR.getValue("sys_id");
  now_GR.next();
```
var restoreID = now_GR.getValue("sys_id");
now_GR.saveLocation();
now_GR.next();
var lastID = now_GR.getValue("sys_id");
now_GR.restoreLocation();
now_GR.next();
var thisID = now_GR.getValue("sys_id");
var progress = "first id=" + firstID
 + "\n\t last id=" + lastID
 + "\n\t saved id=" + restoreID
 + "\n\t restored id=" + thisID;
gs.print("Progress:\\n" + progress);
}

GlideRecord - setAbortAction(Boolean b)

Sets a flag to indicate if the next database action (insert, update, delete) is to
be aborted.

Use in an onBefore business rule to prevent the database action from being
done. The business rule continues to run after setAbortAction() is called. Calling
setAbortAction() does not stop subsequent business rules from executing. Calling
this method only prevents the database action from occurring.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>Boolean</td>
<td>True to abort next action, or false to allow the next action.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

if (!(current.u_date1.nil()) && (!current.u_date2.nil())) {
  var start = current.u_date1.getGlideObject().getNumericValue();
  var end = current.u_date2.getGlideObject().getNumericValue();
  if (start > end) {
    gs.addInfoMessage('start must be before end');
    current.u_date1.setError('start must be before end');
    current.setAbortAction(true);
  }
Scoped equivalent

To use the `setAbortAction()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - setAbortAction(Boolean b)**.

**GlideRecord - setDisplayValue(String name, Object value)**

Sets the specified field to the specified display value.

For a reference field this is the display value for the table. For a date/time this is the time in the caller's current timezone.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field for which to set the display value.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>Display value for the specified field.</td>
</tr>
</tbody>
</table>

**Parameters**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
now_GR.get('46f09e75a9fe198100f4f6d366d17b');
now_GR.setDisplayValue('opened_at','2011-02-13 4:30:00');
now_GR.update();
```

**GlideRecord - setForceUpdate(Boolean force)**

Updates the record even if fields have not changed.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>force</td>
<td>Boolean</td>
<td>True to update even if fields have not changed, otherwise false.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to force a record in the itfm_cost_model table to update even without changes.

```javascript
function() {
    gs.log("Update Script: Upgrade_cost_model_data.js started");
    var now_GR = new GlideRecord("itfm_cost_model");
    now_GR.initialize();
    now_GR.addNullQuery("source_table");
    now_GR.query();
    while (now_GR.next()) {
        now_GR.setForceUpdate(true);
        var sourceTable = getSourceTable(now_GR.getValue('clone_from'));
        if (sourceTable) {
            now_GR.setValue("source_table", sourceTable);
            now_GR.setWorkflow(false);
            now_GR.update();
        }
    }
}
```

GlideRecord - setLimit(Number limit)

Sets the maximum number of records to return in the GlideRecord from a query.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>limit</td>
<td>Number</td>
<td>Limit for records to fetch.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example sets the number of records returned in the query to a maximum of ten.
```javascript
var now_GR = new GlideRecord('incident');
now_GR.orderByDesc('sys_created_on');
now_GR.setLimit(10);
now_GR.query();
```

**Scoped equivalent**

To use the `setLimit()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - setLimit(Number maxNumRecords)`.

**GlideRecord - setLocation(Number rowNumber)**

Sets the current row location to the specified value.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rowNumber</td>
<td>Number</td>
<td>Row number to set as the current row.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to set the record position in the Incident table

```javascript
verifySetLocation : function() {
    var now_GR = new GlideRecord("incident");
    now_GR.query();
    var recordIDs = new Array();
    while(now_GR.next()) {
        recordIDs.push(now_GR.getValue("sys_id"));
    }
    for (var ix = recordIDs.length - 1; ix >= 0; ix--) {
        now_GR.setLocation(ix);
        Assert.assertEquals(recordIDs[ix], now_GR.getValue("sys_id"),
            "The entry retrieved for the index "+ ix + " is not valid";
    }
}
```
**GlideRecord - setNewGuid()**

Generates a new GUID and sets it as the unique ID (sys_id) for the current record.

This function applies only to new records. You cannot change the GUID for an existing record.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the current record.</td>
</tr>
</tbody>
</table>

This example creates a new task record and stores the ID in the task_rel_task table.

```javascript
var task = new GlideRecord ('task');
var tsk_id = task.setNewGuid();

task.description = "Request: " + current.request.number;
task.description = task.description + "\n" + "Requested by: " +
current.request.u_requested_by.name;
task.description = task.description + "\n" + "Requested for: " +
current.request.u_requested_for.name;
task.description = task.description + "\n" + "Item: " + current.cat_item.name;

var now_GR = new GlideRecord ('task_rel_task');
//link the incident to the request
now_GR.parent = current.request;
now_GR.child = tsk_id;
now_GR.insert();
```

**GlideRecord - setNewGuidValue (String guid)**

Generates a new GUID and sets it as the unique ID for the current record, when inserting a new record.
This example generates a new GUID and sets it as the unique ID for the newly created `cmdb_software_instance` record.

```javascript
var gobj = new GlideRecord('sys_db_object');
gobj.addQuery('name','cmdb_software_instance');
gobj.query();
if (!gobj.next()) {
  var si = new GlideRecord('cmdb_software_instance');
  si.query();
  var count = 0;
  while (si.next()) {
    if (!si.isValidField('sys_class_name')) {
      var ci = new GlideRecord('cmdb_ci');
      ci.name = si.name;
      ci.setNewGuidValue(si.sys_id);
      ci.sys_class_name = 'cmdb_software_instance';
      ci.insert();
      count++;
    }
  }
}
```

**Scoped equivalent**

To use the `setNewGuidValue()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - setNewGuidValue(String guid)`.

**GlideRecord - setQueryReferences(Boolean queryReferences)**

Enables or disables using the reference field's display name when querying a reference field.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>queryReferences</td>
<td>Boolean</td>
<td>Flag indicating what time of data to generate. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Generate a string of display names.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Generate a string of sys_ids.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var grByName = new GlideRecord(this.TEST_TABLE);
grByName.addQuery("caller_id", userDisplayName);
grByName.setQueryReferences(true);
grByName.query();
if (grByName.hasNext()) {
    while(grByName.next()) {
        gs.print("Incident caller_id=" + grByName.caller_id);
    }
} else {
    gs.print("NO RESULTS");
}
```

GlideRecord - setUseEngines(Boolean e)

Disables or enables the running of any engines (approval rules / assignment rules).

⚠️ **Warning:** Disabling the running of engines can have a significant impact on your ServiceNow® instance and how it operates. Ensure that you thoroughly test this change before deploying it to production.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>e</td>
<td>Boolean</td>
<td>Flag that indicates whether to enable or disable the running of any engines.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Disable engines.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Enable engines.</td>
</tr>
</tbody>
</table>
This example shows how to disable engines and business rules before executing a query.

```javascript
function auditOAuthInboundRequestsUsage()
{
    var now_GR = new GlideRecord("oauth_credential");
    var oauthClient = now_GR.addJoinQuery("oauth_entity", "peer", "sys_id");
    now_GR.addQuery("type", "access_token");
    now_GR.addQuery("expires", ">", nowDateTime());
    now_GR.addNullQuery("oauth_requestor_profile");
    oauthClient.addCondition("active", "true");
    oauthClient.addCondition("type", "client");
    now_GR.setUseEngines(false);
    now_GR.setWorkflow(false);
    now_GR.query();
    return now_GR.hasNext();
}
```

**GlideRecord - setValue(String name, Object value)**

Sets the specified field to the specified value.

Normally a script would do a direct assignment, for example, `now_GR.category = value`. However, if in a script the element name is a variable, then you can use `now_GR.setValue(elementName, value)`. When setting a value, ensure the data type of the field matches the data type of the value you enter.

If the value parameter is null, the record is not updated, and an error is not thrown.

**Note:** This method cannot be used on journal fields, use `GlideElement.setJournalEntry()` instead.
Note: If the Column Level Encryption Enterprise plugin is enabled and the instance has access to the key, this method can insert encrypted data into encrypted fields. If the instance does not have access to the key, this method returns an error. For more information, see Column Level Encryption Enterprise.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field whose value you want to set.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>Value to set in the specified field.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to set the value of the state field in the planned_task table.

function() {
    var topTask = new GlideRecord('planned_task');
    topTask.setValue('state', -5);
    var childTask = new GlideRecord('planned_task');
    childTask.setValue('state', -5);
    var s = new PlannedTaskStateManagement(childTask, topTask);
    var state = s/manageStateChange(false);
    Assert.assertEquals("-5", state);
}

Scoped equivalent

To use the setValue() method in a scoped application, use the corresponding scoped method: Scoped GlideRecord - setValue(String name, Object value).

GlideRecord - setWorkflow(Boolean e)

Enables or disables the running of business rules that might normally be triggered by subsequent actions. If the e parameter is set to false, an insert/update will not be audited. Auditing only happens when the parameter is set to true for a GlideRecord operation.
**Note:** The `setWorkflow()` method is ignored when subsequently using either the `deleteProblem()` or `deleteMultiple()` methods to cascade delete.

**Warning:** Disabling the running of business rules can have a significant impact on your ServiceNow® instance and how it operates. Ensure that you thoroughly test this change before deploying it to production.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| e    | Boolean | Flag that indicates whether to enable or disable the running of business rules. Valid values:  
|      |         | • true: Enable business rules  
|      |         | • false: Disable business rules |

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
doit('name1','name2');

function doit(username1,username2) {

    var usr1 = new GlideRecord('sys_user');
    var usr2 = new GlideRecord('sys_user');
    var num = 0;

    if (usr1.get('user_name',username1) && usr2.get('user_name',username2)) {
        var ref;
        var dict = new GlideRecord('sys_dictionary');
        dict.addQuery('reference','sys_user');
        dict.addQuery('internal_type','reference');
        dict.query();
        while (dict.next()) {
            num = 0;
            ref = new GlideRecord(dict.name.toString());
            ref.addQuery(dict.element,usr1.sys_id);
            ref.query();
            while (ref.next()) {
```
ref.setValue(dict.element.toString(),usr2.sys_id);
ref.setWorkflow(false);
ref.update();
num++;
}
if (num > 0) {
    gs.print(dict.element + ' changed from ' + usr1.user_name +
    ' to ' + usr2.user_name + ' in ' + num + ' ' + dict.name + ' records');
}

Scoped equivalent
To use the setWorkflow() method in a scoped application, use the corresponding scoped method: Scoped GlideRecord - setWorkflow(Boolean enable).

GlideRecord - update(Object reason)
Updates the GlideRecord with any changes that have been made. If the record does not exist, it is inserted.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reason</td>
<td>Object</td>
<td>Optional. Reason for the update. The reason appears in the audit record.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The sys_id of the new or update record. Returns null if the update fails.</td>
</tr>
</tbody>
</table>

This example updates a record in the task_ci table.

```javascript
var now_GR = new GlideRecord('task_ci');
now_GR.addQuery();
now_GR.query();
var count = now_GR.getRowCount();
if (count > 0) {
    var allocation = parseInt(10000 / count) / 100;
```
while (now_GR.next()) {
    now_GR.u_allocation = allocation;
    now_GR.update();
}

Scoped equivalent

To use the `update()` method in a scoped application, use the corresponding scoped method: `Scoped GlideRecord - update(String reason)`.

### GlideRecord - updateMultiple()

Updates each GlideRecord in a stated query with a specified set of changes.

For information on adding journal entries, refer to the `setJournalEntry()` method.

⚠️ **Note:** To ensure expected results, use the `setValue()` method instead of direct assignments. That is, use `gr.setValue('<field_name>', '4')`; instead of `gr.<field_name> = 4`.

⚠️ **Note:** Do not use this method with the `chooseWindow()` or `setLimit()` methods when working with large tables.

This method sets new values and does not clear existing values. To clear an existing value, use the `setValue()` method and set the field to `null`.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to update the state of all active incidents to 4 - "Awaiting User Info".

```javascript
var now_GR = new GlideRecord('incident');
now_GR.addQuery('active', true);
now_GR.setValue('state', 4);
now_GR.updateMultiple();
```
Scoped equivalent

To use the `updateMultiple()` method in a scoped application, use the corresponding scoped method: **Scoped GlideRecord - updateMultiple().**

GlideRecord - `updateWithReferences(Object reason)`

Updates a record and also inserts or updates any related records with the information provided.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reason</td>
<td>Object</td>
<td>Reason for the updates. The reason is displayed in the audit record.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The sys_id for the record being updated.</td>
</tr>
</tbody>
</table>

If processing an incident where the Caller ID is set to reference sys_user record 'John Doe,' then the following code would update John Doe's user record. If processing an incident where there is no Caller ID specified, then the following code would create a new sys_user record with the provided information (first_name, last_name) and set the Caller ID value to the newly created sys_user record.

```javascript
var inc = new GlideRecord('incident');
inc.get(inc_sys_id);  // Looking up an existing incident record where 'inc_sys_id'
                      // represents the sys_id of a incident record
inc.caller_id.first_name = 'John';
inc.caller_id.last_name = 'Doe';
inc.updateWithReferences();
```

GlideRecord - Scoped

Scoped GlideRecord is used for database operations.

The GlideRecord API is the primary means of interfacing with the database on the server-side code. A GlideRecord is an object that contains records from a single table. Use the API to instantiate a GlideRecord object and add query parameters, filters, limits, and ordering.
For information on a class that performs the same functions as GlideRecord and enforces ACLs, see Using GlideRecordSecure.

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an insert(), update(), deleteRecord(), or deleteMultiple() method on bad query results can result in data loss.

You can set the glide.invalid_query.returns_no_rows system property to true to have queries with invalid encoded queries return no records.

Retrieve values from records

In most cases, do not use dot-walking to get values from a record. Dot-walking retrieves the entire object instead of the field value. Retrieving the object uses much more storage and might cause undesirable results when used in arrays or in Service Portal.

Instead of retrieving the entire object, you can use one of the following methods to copy the field values:

• getValue()
• getDisplayValue()

If dot-walking through a GlideElement object is necessary, use the toString() method to retrieve values. For example, you might need the current caller's manager sys_id to set another reference field. The following example shows how to get the string value instead of the entire object:

```javascript
var mgr = current.caller_id.manager.toString();
```

• GlideAggregate
• GlideElement
• GlideQuery

Scoped GlideRecord - addActiveQuery()

Adds a filter to return active records.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>Filter to return active records.</td>
</tr>
</tbody>
</table>

```javascript
var inc = new GlideRecord('incident');
inc.addActiveQuery();
inc.query();
```

Scoped GlideRecord - `addEncodedQuery(String query)`

Adds an encoded query to other queries that may have been set.

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.

You can set the `glide.invalid_query.returns_no_rows` system property to true to have queries with invalid encoded queries return no records.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>String</td>
<td>An encoded query string.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var queryString = "priority=1^ORpriority=2";
var now_GR = new GlideRecord('incident');
```
Scoped GlideRecord - addFunction(Object function)
Applies a pre-defined GlideDBFunctionBuilder object to a record.

Use the GlideDBFunctionBuilder scoped class to define a function. After the
function is defined, use the addFunction(Object function) method to apply the
function to a record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>function</td>
<td>Object</td>
<td>GlideDBFunctionBuilder object that defines a SQL operation.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var functionBuilder = new GlideDBFunctionBuilder();
var myAddingFunction = functionBuilder.add();
myAddingFunction = functionBuilder.field('order');
myAddingFunction = functionBuilder.field('priority');
myAddingFunction = functionBuilder.build();

// Query incidents in which order + priority is less than 5 and display that added value
var now_GR = new GlideRecord('incident');
now_GR.addFunction(myAddingFunction);
now_GR.addQuery(myAddingFunction, '<', 5);
now_GR.query();
while(now_GR.next())
    gs.info(now_GR.getValue(myAddingFunction));
```

Output:

1
4
3
Scoped GlideRecord – addJoinQuery(String joinTable, String primaryField, String joinTableField)

Adds a filter to return records based on a relationship in a table related to the current GlideRecord.

You can use this method to find all the users that are in the database group via the Group Member [sys_user_grmember] table, or to find all problems that have an assigned incident via the incident.problem_id relationship.

This is not a true database join; rather, addJoinQuery() adds a subquery. So, while the result set is limited based on the join, the only fields that you have access to are those on the base table (those which are in the table with which the GlideRecord was initialized.)

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an insert(), update(), deleteRecord(), or deleteMultiple() method on bad query results can result in data loss.

You can set the glide.invalid_query.returns_no_rows system property to true to have queries with invalid encoded queries return no records.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>joinTable</td>
<td>String</td>
<td>Name of table to use in the join, such as 'incident'.</td>
</tr>
<tr>
<td>primaryField</td>
<td>String</td>
<td>Optional. Name of the field in the GlideRecord to use to join the field specified in the joinTableField parameter. Default: sys_id</td>
</tr>
<tr>
<td>joinTableField</td>
<td>String</td>
<td>Optional. Name of the field in the table specified in joinTable to use to join the tables. Default: First field in the table specified in joinTable that is a reference field to the current GlideRecord table.</td>
</tr>
</tbody>
</table>
## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>Filter that lists records where the relationships match.</td>
</tr>
</tbody>
</table>

Find problems that have an incident attached. This example returns problems that have associated incidents. However, it won't pull values from the incidents that are returned as a part of the query.

```javascript
var prob = new GlideRecord('problem');
prob.addJoinQuery('incident');
prob.query();
```

Find inactive problems with associated incidents.

```javascript
// Look for Problem records that have associated Incident records
var now_GR = new GlideRecord('problem');
var grSQ = now_GR.addJoinQuery('incident');

// Where the Problem records are "active=false"
now_GR.addQuery('active', 'false');

// And the Incident records are "active=true"
grSQ.addCondition('active', 'true');

// Query
now_GR.query();

// Iterate and output results
while (now_GR.next()) {
    gs.info(now_GR.getValue('number'));
}
```

Find problems that have incidents associated where the incident `caller_id` field value matches that of the problem `opened_by` field.

```javascript
var now_GR = new GlideRecord('problem');
    now_GR.addJoinQuery('incident', 'opened_by', 'caller_id');
now_GR.query();
```

## Scoped GlideRecord - addNotNullQuery(String fieldName)

A filter that specifies records where the value of the field passed in the parameter is not null.
Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.

You can set the `glide.invalid_query.returns_no_rows` system property to true to have queries with invalid encoded queries return no records.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The name of the field to be checked.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>A filter that specifies records where the value of the field passed in the parameter is not null.</td>
</tr>
</tbody>
</table>

```javascript
var target = new GlideRecord('incident');
target.addNotNullQuery('short_description');
target.query(); // Issue the query to the database to get all records where short_description is not null
while (target.next()) {
    // add code here to process the incident record
}
```

### Scoped GlideRecord - addNullQuery(String fieldName)

Adds a filter to return records where the value of the specified field is null.

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.
You can set the `glide.invalid_query.returns_no_rows` system property to true to have queries with invalid encoded queries return no records.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The name of the field to be checked.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>The query condition added to the GlideRecord.</td>
</tr>
</tbody>
</table>

```javascript
var target = new GlideRecord('incident');
target.addNullQuery('short_description');
target.query();  // Issue the query to the database to get all records where
                 // short_description is null
while (target.next()) {
    // add code here to process the incident record
}
```

**Scoped GlideRecord - addQuery(String query)**

Adds a filter to return records using an encoded query string.

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.

You can set the `glide.invalid_query.returns_no_rows` system property to true to have queries with invalid encoded queries return no records.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>String</td>
<td>An encoded query string.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>The query condition added to the GlideRecord.</td>
</tr>
</tbody>
</table>

```javascript
var rec = new GlideRecord('incident');
rec.addQuery('active=true');
rec.query();
while (rec.next()) {
    rec.setValue('active', false);
    gs.info('Active incident ' + rec.getValue('number') + ' closed');
    rec.update();
}
```

**Scoped GlideRecord - addQuery(String name, Object value)**

Build a search query and return the rows that match the request.

If you are familiar with SQL, this method is similar to the "where" clause. One or more `addQuery()` calls can be made in a single query; in this case the queries are AND’ed. If any of the query statements need to be OR’ed, use the `GlideQueryCondition` method `addOrCondition()`.

When `addQuery()` is called with only two parameters, table name and comparison value, such as `myObj.addQuery('category','Hardware')`, the operator is assumed to be "equal to".

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.

You can set the `glide.invalid_query.returns_no_rows` system property to true to have queries with invalid encoded queries return no records.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Table field name. If you are not querying a table field, use these reserved variables:</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>123TEXTQUERY321</td>
<td></td>
<td>Adds a search term to the query. Use this option to return matching values from any field in the table. Use the term you want to query as the value.</td>
</tr>
<tr>
<td>123TEXTINDEXGROUP321</td>
<td></td>
<td>Adds a text index group to the query. Use the name of the text index group from the Text Index Groups [ts_index_group] table you want to query as the value. For more information about text index groups, see Configure multiple tables for indexing and searching.</td>
</tr>
</tbody>
</table>

value Object Value on which to query (not case-sensitive).

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>Query condition added to the GlideRecord.</td>
</tr>
</tbody>
</table>

This code example shows how to query the active records in the incident table and then set them all to inactive.

```javascript
var rec = new GlideRecord('incident');
rec.addQuery('active', true);
rec.query();
while (rec.next()) {
    rec.setValue('active', false);
    rec.update();
}
```

Adds a query for records in the kb_knowledge table and portal text index group.

```javascript
var now_GR = new GlideRecord("kb_knowledge");
now_GR.addQuery("123TEXTQUERY321", "email server");
now_GR.addQuery("123TEXTINDEXGROUP321", "portal");
now_GR.query();
```

Scoped GlideRecord - addQuery(String name, String operator, Object value)

Provides the ability to build a request, which when executed, returns the rows from the specified table, that match the request.
If you are familiar with SQL, this method is similar to the "where" clause. One or more `addQuery()` calls can be made in a single query; in this case the queries are AND'ed. If any of the query statements need to be OR'ed, use the `GlideQueryCondition` method `addOrCondition()`.

Always test queries on a sub-production instance prior to deploying them on a production instance. An incorrectly constructed encoded query, such as including an invalid field name, produces an invalid query. When the invalid query is run, the invalid part of the query condition is dropped, and the results are based on the valid part of the query, which may return all records from the table. Using an `insert()`, `update()`, `deleteRecord()`, or `deleteMultiple()` method on bad query results can result in data loss.

You can set the `glide.invalid_query.returns_no_rows` system property to true to have queries with invalid encoded queries return no records.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Table field name.</td>
</tr>
<tr>
<td>operator</td>
<td>String</td>
<td>Query operator. The available values are dependent on the data type of the value parameter. Numbers:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• =</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• !=</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &gt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &gt;=</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &lt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• &lt;=</td>
</tr>
<tr>
<td>Strings (must be in upper case):</td>
<td></td>
<td>• =</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• !=</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• IN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• NOT IN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• STARTSWITH</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ENDSWITH</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CONTAINS</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>Object</td>
<td>Value on which to query (not case-sensitive).</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideQueryCondition</td>
<td>The query condition that was added to the GlideRecord.</td>
</tr>
</tbody>
</table>

```javascript
var rec = new GlideRecord('incident');
rec.addQuery('active', true);
rec.addQuery('sys_created_on', '>', '2010-01-19 04:05:00');
rec.query();
while (rec.next()) {
    rec.setValue('active', false);
    gs.info('Active incident ' + rec.getValue('number') + ' closed');
    rec.update();
}
```

Using the IN operator.

```javascript
var now_GR = new GlideRecord('incident');
now_GR.addQuery('number', 'IN', 'INC00001,INC00002');
now_GR.query();
while (now_GR.next()) {
    //do something....
}
```

**Scoped GlideRecord - addValue(String field, Number value)**

Provides atomic add and subtract operations on a specified number field at the database level for the current GlideRecord object.

Typically, a GlideRecord object is written as one record in a database. Individual field values are stored as defined. For code that adds a value to a GlideRecord field, it simply saves the field to the database with the new value, rather than atomically incrementing it.
For example, when the following code is executed, the value of the u_count field in the database is 2.

```java
gs.info(now_GR.u_count); // "1"
now_GR.u_count += 1;
now_GR.update();
now_GR.get(now_GR.sys_id);
gs.info(now_GR.u_count); // "2"
```

If another user concurrently runs identical code, instead of the two operations each adding 1 to u_count, the net effect is that u_count only contains 2, with one operation's update actually being lost. Conversely, the `addValue()` method performs the addition/subtraction in the database when the record is updated as an atomic operation. Two operations running concurrently each properly update the field.

```java
gs.info(now_GR.u_count); // "1"
now_GR.addValue("u_count", 1);
now_GR.update();
now_GR.get(now_GR.sys_id); // The record must be reloaded from the database to observe the result
gs.info(now_GR.u_count); // "3", if executed concurrently with another user
```

⚠️ **Note:** The new value is not read back from the database unless explicitly done so.

Like `setValue()`, `addValue()` changes only take effect in the database after a subsequent call to `update()` or `insert()`. If `insert()` is called, the specified field is initialized with the `value` parameter passed into `addValue()`.

⚠️ **Note:** If `setValue()` is called for the specified field prior to calling `addValue()`, the `addValue()` method is not processed and an error message is logged.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>The name of the field in this GlideRecord to modify. If the associated field is not a numeric type, the operation is ignored.</td>
</tr>
<tr>
<td>value</td>
<td>Number</td>
<td>The amount to add to the value when the record is saved. To perform a subtraction operation, simply pass a negative value.</td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Shows a value being added.

```java
gs.info(now_GR.u_count); // "1"
now_GR.addValue("u_count", 1);
now_GR.update();
now_GR.get(now_GR.sys_id); // The record must be reloaded from the database to observe the result
gs.info(now_GR.u_count);
```

Output: 2

Shows a value being subtracted.

```java
gs.info(now_GR.u_count); // "4"
now_GR.addValue("u_count", -1);
now_GR.update();
now_GR.get(now_GR.sys_id); // The record must be reloaded from the database to observe the result
gs.info(now_GR.u_count);
```

Output: 3

### Scoped GlideRecord - applyEncodedQuery(String queryString)

Sets the values of the specified encoded query terms and applies them to the current GlideRecord.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>queryString</td>
<td>String</td>
<td>Encoded query to apply to the current GlideRecord.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
```javascript
function createAcl(table, role) {
    gs.info("Checking security on table "+table);
    var now_GR = new GlideRecord("sys_security_acl");
    now_GR.addQuery("name", table);
    now_GR.addQuery("operation", "read");
    now_GR.query();
    var encQuery = now_GR.getEncodedQuery();
    if (now_GR.next()) {
        // existing acl found so use it
        createAclRole(now_GR.getValue('sys_id'), role);
        return;
    } else {
        now_GR.initialize();
        now_GR.applyEncodedQuery(encQuery);
        var acl = now_GR.insert();
        gs.info("Added read access control on "+table);
        createAclRole(acl, role);
    }
}
```

**Scoped GlideRecord - canCreate()**

Determines if the Access Control Rules, which include the user's roles, permit inserting new records in this table.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the user's roles permit creating of records in this table. Valid values: • true: Creating permitted • false: Creating is not permitted</td>
</tr>
</tbody>
</table>

This code example writes whether the current user can create records in the Incident table in the system log.
var now_GR = new GlideRecord('incident');
gs.info(now_GR.canCreate());

Scoped GlideRecord - canDelete()
Determines if the Access Control Rules, which include the user's roles, permit deleting records in this table.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates whether the user's roles permit deleting of records in this table. Valid values:  
- true: Deleting permitted  
- false: Deleting is not permitted |

This code example writes whether the current user can delete records in the Incident table in the system log.

var att = new GlideRecord('sys_attachment');
gs.info(att.canDelete());

Scoped GlideRecord - canRead()
Determines if the Access Control Rules, which include the user's roles, permit reading records in this table.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean  | Flag that indicates whether the user's roles permit reading of records in this table. Valid values:  
  • true: Reading permitted  
  • false: Reading is not permitted |

This code example writes whether the current user can read records in the Incident table in the system log.

```javascript
var now_GR = new GlideRecord('incident');
gs.info(now_GR.canRead());
```

### Scoped GlideRecord - canWrite()

Determines if the Access Control Rules, which include the user's roles, permit editing records in this table.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean  | Flag that indicates whether the user's roles permit writing of records in this table. Valid values:  
  • true: Writing permitted  
  • false: Writing is not permitted |

This code example writes whether the current user can delete records in the Incident table in the system log.

```javascript
var now_GR = new GlideRecord('incident');
gs.info(now_GR.canWrite());
```
Scoped/Global GlideRecord - chooseWindow(Number firstRow, Number lastRow, Boolean forceCount)

Sets a range of rows to be returned by subsequent queries.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>firstRow</td>
<td>Number</td>
<td>First row to include. Because the index starts at 0, a value of 0 returns the first row.</td>
</tr>
<tr>
<td>lastRow</td>
<td>Number</td>
<td>0-based row number of the first row NOT to return. Behaves similar to Java's String.substring(a,b) method. For example, if lastRow = 4 and firstRow = 2, two records are returned (4-2).</td>
</tr>
</tbody>
</table>
| forceCount| Boolean| Optional. Flag that indicates whether to force a row count query. In most implementations of this call, the row count is performed. There are some outlying cases, such as text searches, were a row count is not performed. Setting this flag ensures that the row count occurs. Valid values:
  • true: Row count always occurs.
  • false: Row count occurs if implemented in normal execution of method. Default: false |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example show returning records 3 and 4 from the Incident table.

```javascript
var now_GR = new GlideRecord('incident');
now_GR.orderBy('number');
now_GR.chooseWindow(2, 4);
now_GR.query();
while (now_GR.next()) {
  gs.info(now_GR.getValue('number') + ' is within window');
}
```
Output

```nohighlight
*** Script: INC00000003 is within window
*** Script: INC00000004 is within window
```

**Scoped GlideRecord - deleteMultiple()**

Deletes multiple records that satisfy the query condition.

This method does not delete attachments.

Do not use `deleteMultiple()` on tables with currency fields, delete these records individually. Also, do not use this method with the `chooseWindow()` or `setLimit()` methods when working with large tables.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```nohighlight
var now_GR = new GlideRecord('incident');
now_GR.addQuery('active','false'); // To delete all inactive incidents
now_GR.query();
now_GR.deleteMultiple();
```

**Scoped GlideRecord - deleteRecord()**

Deletes the current record.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean  | Flag that indicates whether the record was successfully deleted. Valid values:  
  • true: Record was deleted.  
  • false: No record was found to delete.                                                                                                                                 |

```javascript
var now_GR = new GlideRecord('incident');
// to delete one record
if (now_GR.get('99ebb4156fa831005be8883e6b3ee4b9'))
  now_GR.deleteRecord();
```

Scoped GlideRecord - get(Object name, Object value)

Returns the specified record in the current GlideRecord object.

This method accepts either one or two parameters. If only a single parameter is passed in, the method assumes that it is the sys_id of the desired record. If not found, it then tries to match the value against the display value. If two parameters are passed in, the first is the name of the column within the GlideRecord to search. The second is the value to search for.

If multiple records are found, use `next()` to access the additional records.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Object</td>
<td>Optional. Name of the instantiated GlideRecord column to search for the specified <code>value</code> parameter. If only a single parameter is passed in, the method assumes that this parameter is the sys_id or display value.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>Value to match.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Indicates whether the requested record was located:</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• true:</td>
<td>record was found</td>
</tr>
<tr>
<td>• false:</td>
<td>record was not found</td>
</tr>
</tbody>
</table>

This example shows how to obtain an incident record by passing in the sys_id.

```javascript
var grIncident = new GlideRecord('incident');
var returnValue = grIncident.get('99ebb4156fa831005be8883e6b3ee4b9');
gs.info(returnValue); // logs true or false
gs.info(grIncident.short_description); // logs Incident Short description
```

This example shows how to obtain an incident record by passing the field to search (caller_id.name) and the value to match within that field.

```javascript
var grIncident = new GlideRecord('incident');
var returnValue = grIncident.get('caller_id.name','Sylivia Wayland');
gs.info(returnValue); // logs true or false
gs.info(grIncident.getValue('number')); // logs Incident Number
```

**Scoped GlideRecord - getAttribute(String fieldName)**

Returns the dictionary attributes for the specified field.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Field name for which to return the dictionary attributes</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Dictionary attributes</td>
</tr>
</tbody>
</table>

```javascript
function doit() {
    var now_GR = new GlideRecord('sys_user');
    now_GR.query("user_name","admin");
    if (now_GR.next()) {
        gs.info("we got one");
    }
}
Scoped GlideRecord - getClassDisplayValue()

Returns the current table's label.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Label that identifies the table.</td>
</tr>
</tbody>
</table>

This example prints the label of the passed in table.

```javascript
// Display the incident table label
var now_GR = new GlideRecord("incident");
var value = now_GR.getClassDisplayValue();
gs.info("The table label is " + value + ".");
```

Output:

```
The table label is Incident.
```

Scoped GlideRecord - getDisplayValue()

Retrieves the display value for the current record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Display value for the current record.</td>
</tr>
</tbody>
</table>

This example writes the display value of a specified incident record into the log.

```javascript
var now_GR = new GlideRecord('incident');
now_GR.get('sys_id','<sys_id>');
gs.info(now_GR.getDisplayValue());
```

Output:

```
INC0000050
```

Scoped GlideRecord - getED()

Returns the element's descriptor.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideElementDescriptor</td>
<td>The element's descriptor.</td>
</tr>
</tbody>
</table>

This example shows how to retrieve the name field for an incident GlideRecord.

```javascript
var grInc = new GlideRecord('incident');
grInc.get('sys_id','ef43c6d40a0b5700c77f9bf387afe3');

var field = grInc.getElementById('priority');
var ed = field.getED();

var isEdge = ed.getLabel();
gs.info("Label is - " + isEdge);
```

Output:

```
Label is - Priority
```
Scoped GlideRecord - getElement(String fieldName)

Retrieves the GlideElement object for the specified field.

The value returned by this method is a complete GlideElement object. The results are the equivalent of dot-walking a field value. For example, `now_GR.getElement('short_description')` provides the same result as `nowGR.short_description`.

In most cases, do not use dot-walking to get values from a record. Dot-walking retrieves the entire object instead of the field value. Retrieving the object uses much more storage and might cause undesirable results when used in arrays or in Service Portal.

Instead of retrieving the entire object, you can use one of the following methods to copy the field values:

- `getValue()`
- `getDisplayValue()`

If dot-walking through a GlideElement object is necessary, use the `toString()` method to retrieve values. For example, you might need the current caller's manager sys_id to set another reference field. The following example shows how to get the string value instead of the entire object:

```javascript
var mgr = current.caller_id.manager.toString();
```

See also:

- GlideElement – `toString()`
- `getElements()`

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Column name for which to return the GlideElement object.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideElement</td>
<td>The GlideElement for the specified column of the current record. Each object describes a field in the current GlideRecord.</td>
</tr>
</tbody>
</table>
The following example shows how to add a new incident record with details in the **Short Description** field.

```javascript
var elementName = 'short_description';
var now_GR = new GlideRecord('incident');
now_GR.newRecord();
now_GR.setValue(elementName, "My DB is not working");
now_GR.insert();

var sdesc = now_GR.getElement('short_description');
gs.info(sdesc.getValue());
```

Output:

```
My DB is not working
```

**Scoped GlideRecord - getElements()**

Returns an array of GlideElement objects. Each object describes a field in the current GlideRecord.

If dot-walking through a GlideElement object is necessary, use the `toString()` method to retrieve values. For example, you might need the current caller's manager sys_id to set another reference field. The following example shows how to get the string value instead of the entire object:

```javascript
var mgr = current.caller_id.manager.toString();
```

See also:

- GlideElement – toString()
- getElement()

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Array of GlideElement objects. Each object describes a field in the current GlideRecord.</td>
</tr>
</tbody>
</table>
The following example displays the value of the name field for the five most recent records created in the Question [question] table.

```javascript
var now_GR = new GlideRecord('question');
var elementArr = now_GR.getElements();
now_GR.orderByDesc('sys_created_on');
now_GR.setLimit(5);
now_GR.query();

while (now_GR.next()){
    var qNames = now_GR.name.toString();
    elementArr.push(qNames);
    gs.info(qNames);
}
```

Output:

delivery_time_var
delivery_time
sequence
priority
assigned_group

Scoped GlideRecord - getEncodedQuery()

Retrieves the query condition of the current result set as an encoded query string.

For details, see [Encoded query strings](#).

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
now_GR.addQuery('active', true);
now_GR.addQuery('priority', 1);
```
now_GR.query();
var encodedQuery = now_GR.getEncodedQuery();
gs.info(encodedQuery);

Output: active=true\^priority=1

**Scoped GlideRecord - getLabel()**

Returns the field's label.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Field's label</td>
</tr>
</tbody>
</table>

```javascript
template.print("Summary of Requested items:\n");
var now_GR = new GlideRecord("sc_req_item");
now_GR.addQuery("request", current.sysapproval);
now_GR.query();
while(now_GR.next()) {
    var nicePrice = now_GR.price.toString();
    if (nicePrice !="") {
        nicePrice = parseFloat(nicePrice);
        nicePrice = nicePrice.toFixed(2);
    }
    template.print(now_GR.number + ":  " + now_GR.quantity + " X " +
    now_GR.cat_item.getDisplayValue()
    + " at $" + nicePrice + " each \n");
template.print("    Options:\n")
for (key in now_GR.variables) {
    var now_V = now_GR.variables[key];
    if(now_V.getGlideObject().getQuestion().getLabel() !="") {
        template.space(4);
        template.print('     ' +  now_V.getGlideObject().getQuestion().getLabel() + " = "+
        now_V.getDisplayValue() + "\n");
    }
}
Scoped GlideRecord - getLastErrorMessage()
Retrieves the last error message. If there is no last error message, null is returned.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The last error message as a string.</td>
</tr>
</tbody>
</table>

```
// Setup a data policy where short_description field in incident is mandatory
var now_GR = new GlideRecord('incident');
now_GR.insert(); // insert without data in mandatory field
var errormessage = now_GR.getLastErrorMessage();
gs.info(errormessage);
```

Output: Data Policy Exception: Short description is mandatory

Scoped GlideRecord - getLink(Boolean noStack)
Retrieves the link to the current record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| noStack| Boolean    | Flag indicating whether to append the sysparm_stack parameter to the returned link. This parameter specifies the page to visit after closing the current link. Valid values:  
  • true: Do not attach the sysparm_stack parameter.  
  • false: Attach the sysparm_stack parameter. |
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>If true, the sysparm_stack parameter is not appended to the link.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Link to the current record.</td>
</tr>
</tbody>
</table>

This example queries all Incident records with a priority of "1" and writes the servlet URI and the current record's link to the system log.

```javascript
var now_GR = new GlideRecord('incident');
now_GR.addActiveQuery();
now_GR.addQuery("priority", 1);
now_GR.query();
now_GR.next();
gs.info(gs.getProperty('glide.servlet.uri') + now_GR.getLink(false));
```

Output:

https://instance.service-now.com/incident.do?sys_id=46e2fee9a9fe19810049b49dee0daf58&sysparm_stack=incident_list.do?sysparm_query=active=true

---

**Scoped GlideRecord - getRecordClassName()**

Retrieves the class name for the current record.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The class name.</td>
</tr>
</tbody>
</table>
var now_GR = new GlideRecord('incident');
var recordClassName = now_GR.getRecordClassName();
gs.info(recordClassName);

Output: incident

**Scoped GlideRecord - getRowCount()**

Retrieves the number of rows in the query result.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Number</td>
</tr>
</tbody>
</table>

var now_GR = new GlideRecord('incident');
now_GR.query();
gs.info("Records in incident table: " + now_GR.getRowCount());

**Scoped GlideRecord - getTableName()**

Retrieves the name of the table associated with the GlideRecord.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

var now_GR = new GlideRecord('incident');
gs.info(now_GR.getTableName());
Scoped GlideRecord - getUniqueValue()

Gets the primary key of the record, which is usually the sys_id unless otherwise specified.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The unique primary key as a String, or null if the key is null.</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('kb_knowledge');
now_GR.query();
now_GR.next();
var uniqueid = now_GR.getUniqueValue();
gs.info(uniqueid);
```

Scoped GlideRecord - getValue(String name)

Retrieves the string value of an underlying element in a field.

⚠️ **Note:** If the Column Level Encryption Enterprise plugin is enabled and the instance has access to the key, this method returns clear text values from encrypted fields. If the instance does not have access to the key, this method returns the encrypted value. For more information, see Column Level Encryption Enterprise.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the field to get the value from.</td>
</tr>
</tbody>
</table>
## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| String | The string value of the underlying element. Returns null if the field is empty or the field does not exist. Boolean values return as "0" and "1" string values instead of false and true.

```javascript
var now_GR = new GlideRecord('incident');
now_GR.orderBy('number');
now_GR.query('active','true');
now_GR.next();
gs.info(now_GR.getValue('number'));
```

**Output:**

INC0000002

### Scoped GlideRecord - GlideRecord(String tableName)

Creates an instance of the GlideRecord class for the specified table.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The table to be used.</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
```

### Scoped GlideRecord - hasNext()

Determines if there are any more records in the GlideRecord object.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if there are more records in the query result set.</td>
</tr>
</tbody>
</table>
Scoped GlideRecord - insert()

Inserts a new record using the field values that have been set for the current record.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Unique ID of the inserted record, or null if the record is not inserted.</td>
</tr>
</tbody>
</table>

Scoped GlideRecord - initialize()

Creates an empty record suitable for population before an insert.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var grIncident = new GlideRecord('incident');
grIncident.initialize();
grIncident.setValue('short_description', 'New Incident');
grIncident.setValue('description', 'Incident description');
grIncident.insert();

Scoped GlideRecord - isActionAborted()
Checks to see if the current database action is to be aborted.

isActionAborted() is initialized (set to false) for new threads and by the next() method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean| Flag that indicates if the current database action is to be aborted. Valid values:  
• true: The current database action is to be aborted.  
• false: The current database action is not to be aborted. |

var now_GR = new GlideRecord('incident');

gs.info(now_GR.isActionAborted());

Output:

false

Scoped GlideRecord - isEncodedQueryValid(String query)
Verifies whether the specified encoded query is valid.

If the specified encoded query is valid, then the query is applied, just as if you had called addEncodedQuery(). If the specified encoded query is invalid, then sys_idNotValidnull is added as the encoded query.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>String</td>
<td>Encoded query to validate. See <a href="#">Encoded query strings</a>.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the specified encoded query is valid.</td>
</tr>
<tr>
<td>true</td>
<td>Passed-in encoded query is valid</td>
</tr>
<tr>
<td>false</td>
<td>Passed-in encoded query is not valid</td>
</tr>
</tbody>
</table>

This code example shows how to validate an encoded query and then execute logic if the query is valid.

```javascript
var now_GR = new GlideRecord('incident_sla');
var isValidQuery = now_GR.isEncodedQueryValid('inc_impact=1^taskslatable_active=true');
if (isValidQuery) {
    now_GR.query();
}
```

**Scoped GlideRecord - isNewRecord()**

Checks if the current record is a new record that has not yet been inserted into the database.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the record is new and has not been inserted into the database.</td>
</tr>
</tbody>
</table>
```javascript
var now_GR = new GlideRecord("x_app_table");
now_GR.newRecord(); // create a new record and populate it with default values
gs.info(now_GR.isNewRecord());
```

**Scoped GlideRecord - isValid()**

Determines if the current table is valid or if the record was successfully retrieved.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates if the table is valid or if the record was successfully retrieved. Possible values:  
|         | • true: Table is valid or the record was successfully retrieved.  
|         | • false: Table is invalid or the record was not successfully retrieved.     |

```javascript
var comment_GR = new GlideRecord('cf_comment');
var commentId = '99ebb4156fa831005be8883e6b3ee4b9';
comment_GR.get(commentId);
gs.info(comment_GR.isValid());
```

**Scoped GlideRecord - isValidField(String columnName)**

Determines if the specified field is defined in the current table.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columnName</td>
<td>String</td>
<td>The name of the field.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>----------</td>
<td>--------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Boolean</td>
<td>True if the field is defined for the current table.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
now_GR.initialize();
gs.info(now_GR.isValidField("short_description"));
```

**Scoped GlideRecord - isValidRecord()**

Determines if a record was actually returned by the query/get record operation.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether a record was actually returned by the query/get operation. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Record returned by query/get operation.</td>
</tr>
<tr>
<td></td>
<td>• false: End of record set, no record returned.</td>
</tr>
</tbody>
</table>

```javascript
var rec = new GlideRecord('incident');
rec.query();
while (rec.next()) {
    gs.info(rec.number + ' exists');
}
gs.info(rec.isValidRecord());
```

**Scoped GlideRecord - newRecord()**

Creates a new GlideRecord record, sets the default values for the fields, and assigns a unique ID to the record.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord("x_app_table");
now_GR.newRecord();
gs.info(now_GR.isNewRecord());
```

Output: true

 Scoped GlideRecord - next()  
 Moves to the next record in the GlideRecord object.

ℹ️ Note: This method fails if there is a field in the table called "next". If that is the case, use the method Scoped GlideRecord - _next().

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates if there is a "next" record in the GlideRecord. Valid values:  
• true: Move to the next record was successful.  
• false: No more records in the result set. |

Example

```javascript
var rec = new GlideRecord('incident');
rec.query();
```
while (rec.next()) {
    gs.info(rec.getValue('number') + ' exists');
}

Output:

INC0010112 exists
INC0010114 exists
INC0010119 exists
INC0010127 exists

**Scoped GlideRecord - _next()**

Moves to the next record in the GlideRecord. Provides the same functionality as `next()`, use this method if the GlideRecord has a column named `next`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean| Flag that indicates whether there are more records in the query set. Possible values:  
  • true: More records in the query set.  
  • false: No more records in the query set. |

The following example shows how to list each record in the Incidents [incident] table.

```javascript
var rec = new GlideRecord('incident');
rec.query();
while (rec._next()) {
    gs.info(rec.getValue('number') + ' exists');
}
```

Output:

INC0000060 exists
INC0009002 exists
INC0000009 exists
Scoped GlideRecord - operation()

Determines if an operation is insert, update, or delete.

Knowing the operation enables using `current.operation()` to make a generic business rule which can handle each operation uniquely.

For information on using the global variable `current`, refer to Global variables in business rules.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The current operation. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• delete</td>
</tr>
<tr>
<td></td>
<td>• insert</td>
</tr>
<tr>
<td></td>
<td>• update</td>
</tr>
</tbody>
</table>

The following example shows how to use this method in a business rule. The `operation()` method detects which operation triggered an event and performs a different action depending for update and insert operations.

```java
if(current.operation() == "update") {
    current.updates ++; }
if(current.operation() == "insert") {
    current.updates = 0; }
```

Scoped GlideRecord - orderBy(String name)

Specifies an orderBy column.
Call this method more than once to order by multiple columns. Results are arranged in ascending order. To arrange records in descending order, see **Scoped GlideRecord - orderByDesc(String name)**.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Column name to use to order the records in this GlideRecord object.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to order incident records in ascending order by Short Description.

```javascript
var queryString = "priority=2";
var now_GR = new GlideRecord('incident');
now_GR.orderBy('short_description'); // Ascending Order
now_GR.addEncodedQuery(queryString);
now_GR.query();
while (now_GR.next()) {
  gs.info(now_GR.getValue('short_description'));
}
```

Output:

- Can't launch 64-bit Windows 7 virtual machine
- Can't log into SAP from my laptop today
- Network storage unavailable
- Please remove the latest hotfix from my PC

**Scoped GlideRecord - orderByDesc(String name)**

Specifies a descending orderBy column.

Call this method more than once to order by multiple columns. Results are arranged in descending order. To arrange records in ascending order, see **Scoped GlideRecord - orderBy(String name)**.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Column name to use to order the records in a GlideRecord object.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to order incident records in descending order by Short Description.

```javascript
var queryString = "priority=2";
var now_GR = new GlideRecord('incident');
now_GR.orderByDesc('short_description'); //Descending Order
now_GR.addEncodedQuery(queryString);
now_GR.query();
while (now_GR.next()) {
    gs.info(now_GR.getValue('short_description'));
}
```

Output:

Please remove the latest hotfix from my PC
Network storage unavailable
Can't log into SAP from my laptop today
Can't launch 64-bit Windows 7 virtual machine

**Scoped GlideRecord - query(String field, String value)**

Runs a query against the table based on the filters specified by query methods such as `addQuery()` and `addEncodedQuery()`.

This method queries the GlideRecord table as well as any references of the table. For more information, see [Querying tables in script](#).

ℹ️ **Note:** This method fails if there is a field in the table called "query". If that is the case, use the `_query()` method instead.

See also:
- GlideAggregate - Scoped
- GlideQuery - Scoped, Global
- GlideQueryCondition - Scoped

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Optional - must also specify value parameter. Name of the field to search for the value specified in the value parameter.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Optional - must also specify field parameter. Value to search for in the specified field parameter.</td>
</tr>
</tbody>
</table>

**Note:** This method is typically run without arguments, but you can specify a name-value pair to filter records containing the specified values. If the parameters are specified, the "name=value" condition is added to the query.

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to scan the System Dictionary [sys_dictionary] for tables with a query field.

```javascript
var tableArr = [];

var now_GR = new GlideRecord('sys_dictionary');
now_GR.addQuery('element', 'query');
now_GR.setLimit(6);

now_GR.query();

while(now_GR.next()){
    tableArr.push(now_GR.name.getValue());
}
```
gs.info('The following tables have a field column called "query":');

for (i = 0; i < tableArr.length; i++) {
    gs.info(tableArr[i]);
}

Output:

The following tables have a field column called "query":
- cmdb_convert_bulk_services
- cmdb_multisource_query_status
- cmdb_qb_result_base
- cmdb_qb_table_mapping
- discovery_probes_cim_query
- kb_feedback

**Scoped GlideRecord - _query(String field, String value)**

Runs a query against the table based on the filters specified by query methods such as `addQuery()` and `addEncodedQuery()`. This method is intended to be used on tables in which there is a column named “query”, which might cause errors running the `query()` method.

This method queries the GlideRecord table as well as any references of the table. For more information, see [Querying tables in script](#).

See also:
- [GlideAggregate - Scoped](#)
- [GlideQuery - Scoped, Global](#)
- [GlideQueryCondition - Scoped](#)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Optional - must also specify value parameter. Name of the field to search for the value specified in the value parameter.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>Optional - must also specify field parameter. Value to search for in the specified field parameter.</td>
</tr>
</tbody>
</table>

Note: This method is typically run without arguments, but you can specify a name-value pair to filter records containing the specified values. If the parameters are specified, the "name=value" condition is added to the query.

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how query the Knowledge Feedback [kb_feedback] table and list KB articles with comments that include Excel.

```javascript
var rec = new GlideRecord('kb_feedback');
rec.addQuery('comments', 'CONTAINS', 'Excel');
rec._query();
while (rec.next()) {
  gs.info(rec.getDisplayValue('article') + " comment: " + rec.getValue('comments'));}
```

Output:

```javascript
KB0000005 comment:
    Can you please add the version of Excel this applies to? All?
KB0000005 comment:
    Does this work for all Excel versions? OSX and Windows alike?
```

Scoped GlideRecord - setAbortAction(Boolean b)

Sets a flag to indicate if the next database action (insert, update, delete) is to be aborted. This is often used in business rules.

Use in an onBefore business rule to prevent the database action from being done. The business rule continues to run after setAbortAction() is called. Calling
setAbortAction() does not stop subsequent business rules from executing. Calling this method only prevents the database action from occurring.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>Boolean</td>
<td>True to abort the next action. False if the action is to be allowed.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
// Often used in business rule to check whether the current operation should be aborted.
if (current.size > 16) {
    current.setAbortAction(true);
}
```

### Scoped GlideRecord - setLimit(Number maxNumRecords)

Sets the limit for number of records are fetched by the GlideRecord query.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxNumRecords</td>
<td>Number</td>
<td>The maximum number of records to fetch.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
var now_GR = new GlideRecord('incident');
now_GR.orderByDesc('sys_created_on');
now_GR.setLimit(10);
now_GR.query(); // this retrieves latest 10 incident records created
```

### Scoped GlideRecord - setNewGuidValue(String guid)

Sets the sys_id value for the current record.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>guid</td>
<td>String</td>
<td>GUID to assign to the current record.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('incident');
now_GR.setValue('short_description', 'The third floor printer is broken');
now_GR.setNewGuidValue('eb4636ca6f6d31005be8883e6b3ee333');
now_GR.insert();
gs.info(now_GR.getValue('sys_id'));
```

Scoped GlideRecord - setValue(String name, Object value)
Sets the value of the field with the specified name to the specified value.

Normally the script does `now_GR.category = value`. However, if the element name is itself a variable then you can use `now_GR.setValue(elementName, value)`. When setting a value, ensure the data type of the field matches the data type of the value you enter.

⚠️ **Note:** If the Column Level Encryption Enterprise plugin is enabled and the instance has access to the key, this method can insert encrypted data into encrypted fields. If the instance does not have access to the key, this method returns an error. For more information, see Column Level Encryption Enterprise.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the field.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>Value to assign to the field.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var elementName = 'short_description';
var now_GR = new GlideRecord('incident');
now_GR.initialize();
now_GR.setValue(elementName, "My DB is not working");
now_GR.insert();
```

Scoped GlideRecord - `setWorkflow(Boolean enable)`

Enables or disables the running of business rules, script engines, and audit.

⚠️ **Warning:** Disabling the running of business rules, script engines, and audit can have a significant impact on your ServiceNow® instance and how it operates. Ensure that you thoroughly test this change before deploying it to production.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| enable | Boolean | Flag that indicates whether to enable or disable the running of business rules, script engines, and audit. Valid values:  
• true: Enable the running of business rules, script engines, and audit. (Default)  
• false: Disable the running of business rules, script engines, and audit. |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
//Enable business rules, scripts engines for x_app_table
var now_GR = new GlideRecord("x_app_table");
now_GR.setWorkflow(true);
```
Scoped GlideRecord - update(String reason)

Updates the GlideRecord with any changes that have been made. If the record does not already exist, it is inserted.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reason</td>
<td>String</td>
<td>Optional. Reason for the update. The reason appears in the audit record.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the new or updated record. Returns null if the update fails.</td>
</tr>
</tbody>
</table>

The following example shows how to update the Short Description field of an incident.

```javascript
var now_GR = new GlideRecord('incident');
now_GR.get('99ebb4156fa831005be8883e6b3ee4b9');
now_GR.setValue('short_description', 'Update the short description');
now_GR.update();
gs.info(now_GR.getElement('short_description'));
```

Output:

Update the short description.

Scoped GlideRecord - updateMultiple()

Updates each GlideRecord in a stated query with a specified set of changes.

This method does not support adding multiple journal entries.

ℹ️ Note: To ensure expected results, use the setValue() method instead of direct assignments. That is, use `gr.setValue('<field_name>', '4');` instead of `gr.<field_name> = 4`.

ℹ️ Note: Do not use this method with the chooseWindow() or setLimit() methods when working with large tables.

This method sets new values and does not clear existing values. To clear an existing value, use the setValue() method and set the field to `null`.
This example shows how to update the state of all active incidents to 4 - "Awaiting User Info".

```javascript
var now_GR = new GlideRecord('incident');
now_GR.addQuery('active', true);
now_GR.setValue('state', 4);
now_GR.updateMultiple();
```

### GlideRecordUtil - Global

A utility class for working with GlideRecords

The GlideRecordUtil class is available in server-side scripts.

#### GlideRecordUtil - getCIGR(String sys_id)

Returns the GlideRecord object for the specified configuration item (CI) using just the sys_id of the CI.

Use this method to quickly obtain a specific CI without knowing its associated class/table.
The following example returns the GlideRecord object for the specified CI using just the sys_id of the CI.

```javascript
var now_GR = new GlideRecordUtil().getCIGR("2dfd7c8437201000deeabfc8bcb65d56");
```

**GlideRecordUtil - getFields(GlideRecord gr)**

Returns an array of all the fields in the specified GlideRecord.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>gr</td>
<td>GlideRecord</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>Array</td>
<td>Field names for the specified GlideRecord.</td>
</tr>
</tbody>
</table>

```javascript
var queryString = "priority=1^ORpriority=2";
var now_GR = new GlideRecord('incident');
now_GR.addEncodedQuery(queryString);
now_GR.query();
now_GR.next();

var gRU = new GlideRecordUtil();
var fieldList = gRU.getFields(now_GR);
gs.info(fieldList);
```

Output: Line breaks added for presentation.

```javascript
sys_id,skills,closed_by,assigned_to,contract,category,escalation,state,reassignment_count,location,
time_worked,order,due_date,number,upon_approval,sys_tags,sla_due,follow_up,reopen_count,notify,business_stc,
caused_by,rejection_goto,assignment_group,comments_and_work_notes,incident_state,opened_at,
parent_incident,
business_service,wf_activity,calendar_duration,group_list,caller_id,comments,priority,sys_updated_by,
variables,delivery_task,resolved_at,sys_updated_on,parent,active,opened_by,expected_start,watch_list,
company,upon_reject,work_notes,sys_created_by,additional_assignee_list,approval_set,cmdb_ci,user_input,
```
GlideRecordUtil - getGR(String baseTable, String sys_id)

Returns a GlideRecord instance for the given table, positioned to the given sys_id, and of the right class (table).

This method is useful when you need to load a GlideRecord from a sys_id, but you don’t know what the actual table is (because it may be extended from the base table). This method always returns a GlideRecord of the correct type.

**base_table**: the name of the base table that the specified sys_id is in.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseTable</td>
<td>String</td>
<td>The name of the base table containing the sys_id.</td>
</tr>
<tr>
<td>sys_id</td>
<td>String</td>
<td>The sys_id of the desired record.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>The GlideRecord for the specified sys_id.</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecordUtil().getGR("cmdb_ci_computer", "2dfd7c8437201000deeabfc8bcbe5d56");
```

GlideRecordUtil - getTables(String tableName)

Returns a Java ArrayList of the ancestors of the specified table name.

For example, given cmdb_ci_linux_server, this would return cmdb_ci_linux_server, cmdb_ci_server, cmdb_ci_computer, cmdb_ci_hardware, cmdb_ci, and cmdbr.
The following example shows the ancestors of the cmdb_ci_linux_server table.

```plaintext
var tables = new GlideRecordUtil().getTables("cmdb_ci_linux_server");
gs.info("Tables returned: " + tables);
```

**Output:**

```
Tables returned: [cmdb_ci_linux_server, cmdb_ci_server, cmdb_ci_computer, cmdb_ci_hardware,
                 cmdb_ci, cmdb]
```

**GlideRecordUtil - mergeToGR(Object hashMap, GlideRecord now_GR, Object ignore)**

Sets the fields in the specified GlideRecord with the field values contained in the specified hashmap, unless that field name is in the ignore hashmap.

```
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hashMap</td>
<td>Object</td>
<td>An Object instance (being used as a hashmap), with properties named for fields and containing the fields' value.</td>
</tr>
<tr>
<td>GlideRecord</td>
<td>GR</td>
<td>The GlideRecord instance to receive the field values.</td>
</tr>
<tr>
<td>ignore</td>
<td>Object</td>
<td>An optional hashmap of field names to ignore.</td>
</tr>
</tbody>
</table>
```
This example updates a computer record's name and os fields, but does not update the sys_created_by field:

```javascript
var now_GR = new GlideRecordUtil().getGR("cmdb_ci_computer", "2dfd7c8437201000deeabfc8bce5d56");
var obj = {"name": "xyz", "os": "windows 2000", "sys_created_by": "sleek.lin"};
var ignore = {"sys_created_by": true};
new GlideRecordUtil().mergeToGR(obj, now_GR, ignore);
now_GR.update();
```

**GlideRecordUtil - populateFromGR(Object hashMap, GlideRecord now_GR, Object ignore)**

Populates the given hashmap from the given GlideRecord instance. Each field in the GlideRecord becomes a property in the hashmap.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hashMap</td>
<td>Object</td>
<td>An object being used as a hashmap.</td>
</tr>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>A GlideRecord instance positioned to a valid record.</td>
</tr>
<tr>
<td>ignore</td>
<td>Object</td>
<td>An optional hashmap of file names not to populate.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var objectToPopulate = {};
var now_GR = new GlideRecordUtil().getGR("cmdb_ci_computer", "2dfd7c8437201000deeabfc8bce5d56");
var ignore = {"sys CREATED ON": true, "sys UPDATED BY": true};
new GlideRecordUtil().populateFromGR(objectToPopulate, now_GR, ignore);
// Now the objectToPopulate contains field/value pairs from the computer GlideRecord
```

**GlideRecordV3 - Client**

GlideRecord is used for database operations. Client-side GlideRecord enables the use of some GlideRecord functionality in client-side scripts, such as client scripts and UI policy scripts.

A GlideRecord contains both records and fields.
Queries made with the client-side GlideRecord are executed on the server. Therefore, a request is made from the client browser to obtain the record data. Client-side GlideRecord is not supported in scoped applications. Instead, create a script include and use GlideAjax, or use the REST APIs.

**GlideRecordV3 - addOrderBy(String column)**

Adds a column to order by in the query.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>String</td>
<td>The column by which to order the result set.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideRecordV3 - addQuery(String fieldName, Object value)**

Adds a filter to return records where the field is equal to the value (or is in a list of values).

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field to be checked.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>The value or list of values on which to query.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideRecordV3 - addQuery(String fieldName, Object operator, Object value)**

Adds a filter to return records where the field meets the specified condition (field, operator, value).
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field to be checked.</td>
</tr>
<tr>
<td>operator</td>
<td>Object</td>
<td>An operator for the query.</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>The value to use.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### GlideRecordV3 - deleteRecord(Function responseFunction)

Deletes the current record.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>responseFunction</td>
<td>Function</td>
<td>The response function.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the record was deleted. False if no record was found to delete.</td>
</tr>
</tbody>
</table>

### GlideRecordV3 - get(String sysId)

Get a record by sysId.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysId</td>
<td>String</td>
<td>The sysId of the record for which to search.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td></td>
</tr>
<tr>
<td>Boolean</td>
<td>True if one or more matching records was found. False if no records were found.</td>
<td></td>
</tr>
</tbody>
</table>

**GlideRecordV3 - getEncodedQuery()**

Retrieves all query conditions as an encoded query string.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>An encoded query string containing all conditions that have been added to the query.</td>
</tr>
</tbody>
</table>

**GlideRecordV3 - getTableName()**

Gets the name of the table associated with the GlideRecord.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The table name.</td>
</tr>
</tbody>
</table>

**GlideRecordV3 - GlideRecord(String tableName)**

Creates an instance of the GlideRecord class for the specified table.
var now_GR = new GlideRecord('incident');

**GlideRecordV3 - hasNext()**
Determines if there are any more records in the GlideRecord.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if there are more records in the query set.</td>
</tr>
</tbody>
</table>

**GlideRecordV3 - insert(Function responseFunction)**
Inserts a new record using the field values that have been set for the current record.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>responseFunction</td>
<td>Function</td>
<td>The response function.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The sys_id of the inserted record, or null if the record was not inserted.</td>
</tr>
</tbody>
</table>

**GlideRecordV3 - next()**
Moves to the next record in the GlideRecord.
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>False if there are no more records in the query set.</td>
</tr>
</tbody>
</table>

**GlideRecordV3 - orderBy(String column)**

Specifies an orderBy column. May be called more than once to order by multiple columns.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>column</td>
<td>String</td>
<td>The column to add to sort the result set.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**GlideRecordV3 - query()**

Performs a query using the current query conditions. Takes zero or more parameters. Parameters may be in any order. Any function is considered to be a response function. Any pair of literals is considered a query pair (field : value).

Do not make synchronous query calls. Performing a query without a response function makes the call synchronous, which means that the display will wait for the query response before continuing.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of a field to query. (optional)</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>responseFunction</td>
<td>Function</td>
<td>The function called when the query results are available. (optional)</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The field value to query for. (optional)</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
// synchronous call syntax (no response function): DO NOT USE
query();

// asynchronous call syntax
// performs query with current conditions, calls responseFunction when done
query(responseFunction)

// synchronous call syntax (no response function): DO NOT USE
// adds "category=hardware" to current query conditions and performs query
query('category', 'hardware')

// asynchronous call syntax
// adds "category=hardware" to current query conditions, performs query, and calls responseFunction when done
query('category', 'hardware', responseFunction)

// asynchronous call example
// adds "user_name=abel.tuter" to current query conditions, performs query, and calls defined response function when done
function onLoad() {
    var now_GR = new GlideRecord("sys_user");
    now_GR.query("user_name", "abel.tuter", function(now_GR) {
        if (now_GR.next()) {
            alert("You can access fields by name from the client API, just like in the server API:\n            now_GR.name = " + now_GR.name);
            alert("You can also access fields using getValue():\n            now_GR.getValue("email") = " + now_GR.getValue("email"));
            if (now_GR.getDisplayValue) {
```
alert("In Service Portal, Mobile, and Agent Workspace, you can
access a field's display value:\n\n\nnow_GR.getDisplayValue("company\") = " +
now_GR.getDisplayValue("company");
} else {
    alert("On the desktop, you cannot access a field's display value, but can get its
sys_id:\nnow_GR.company = " + now_GR.company);
}
    alert("You cannot dot-walk in the client API:\nnow_GR.company.name = " +
now_GR.company.name);
}
});

GlideSchedule - Scoped

The scoped GlideSchedule API provides methods for performing operations on
GlideSchedule objects, such as adding new schedule segments to a schedule,
determining if a datetime is within the schedule, or setting the schedule
timezone.

Scoped GlideSchedule - add(GlideDateTime startDate, GlideDuration offSet)

Adds a new schedule segment to the current schedule.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startDate</td>
<td>GlideDateTime</td>
<td>The starting date of the new schedule segment.</td>
</tr>
<tr>
<td>offSet</td>
<td>GlideDuration</td>
<td>The time offset of the new schedule segment.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDateTime</td>
<td>The schedule updated with the new schedule segment.</td>
</tr>
</tbody>
</table>

var startDate = new GlideDateTime('2014-01-02');
var days = 2;
var dur = new GlideDuration(60 * 60 * 24 * 1000 * days);
var schedule = new GlideSchedule();
var end = schedule.add(startDate, dur);
gs.info(end);
Scoped GlideSchedule - duration(GlideDateTime startDate, GlideDateTime endDate)
Determines the elapsed time in the schedule between two date time values using the timezone of the schedule or, if that is not specified, the timezone of the session.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startDate</td>
<td>GlideDateTime</td>
<td>The starting datetime.</td>
</tr>
<tr>
<td>endDate</td>
<td>GlideDateTime</td>
<td>The ending datetime.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDuration</td>
<td>The difference between the starting and ending datetime.</td>
</tr>
</tbody>
</table>

```javascript
var startDate = new GlideDateTime('2014-10-16 02:00:00');
var endDate = new GlideDateTime('2014-10-18 04:00:00');
var schedule = new GlideSchedule();

schedule.load('090eeeca0a0a0b260077e1dfa71da828'); // loads "8-5 weekdays excluding holidays" schedule
var duration = schedule.duration(startDate, endDate);
gs.info(duration.getDurationValue()); // gets the elapsed time in schedule
```

Scoped GlideSchedule - getName()
Retrieves the schedule name.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The name of the current schedule.</td>
</tr>
</tbody>
</table>

```java
sys_id = '04e664654a36232701a2247dcd8fc4cf'; // sys_id for "Application" schedule record
var sched = new GlideSchedule(sys_id);
gs.info(sched.getName());
```

**Scoped GlideSchedule - GlideSchedule()**

Instantiates an empty GlideSchedule object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Scoped GlideSchedule - GlideSchedule(String sysID, String timeZone)**

Instantiates a GlideSchedule object and loads the schedule information. If a timezone is not specified or is nil, the current session timezone is used.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysID</td>
<td>String</td>
<td>The system ID for the schedule.</td>
</tr>
<tr>
<td>timeZone</td>
<td>String</td>
<td>The time zone. (Optional)</td>
</tr>
</tbody>
</table>

```java
var schedule = new GlideSchedule('090eecae0a0a0b260077edfa71da828', 'US/Pacific');
```

**Scoped GlideSchedule - isInSchedule(GlideDateTime time)**

Determines if the specified date and time is within the current schedule.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>GlideDateTime</td>
<td>Date and time value to check.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the specified date and time is within the schedule. Valid values: • true: Date and time is within the schedule. • false: Date and time are outside of the schedule.</td>
</tr>
</tbody>
</table>

```java
var glide = new GlideRecord('cmn_schedule');
glide.addQuery('type', 'blackout');
glide.query();
if (glide.next()) {
    var sched = new GlideSchedule(glide.sys_id);
    var date = new GlideDateTime();
    date.setDisplayValue("2007-09-18 12:00:00");
    if (sched.isInSchedule(date))
        gs.info("Is in the schedule");
    else
        gs.info("Is NOT in the schedule");
}
```

Scoped GlideSchedule - isValid()

Determines if the current schedule is valid. A schedule is valid if it has at least one schedule span.

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the schedule is valid.</td>
</tr>
</tbody>
</table>

```java
var glide = new GlideRecord('cmn_schedule');
glide.addQuery('type', 'blackout');
glide.query();
if (glide.next()) {
    var sched = new GlideSchedule(glide.sys_id);
    var date = new GlideDateTime();
    date.setDisplayValue("2007-09-18 12:00:00");
    if (sched.isValid())
        gs.info("Is valid");
    else
        gs.info("Is NOT valid");
}
```
else
gs.info("Is not valid");
}

Scoped GlideSchedule - load(String sysID, String timeZone, String excludeSpanID)
Loads a schedule with the schedule information.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysID</td>
<td>String</td>
<td>The system ID of the schedule.</td>
</tr>
<tr>
<td>timeZone</td>
<td>String</td>
<td>(Optional) The timezone. If a timezone is not specified, or is nil, the session timezone is used for the schedule.</td>
</tr>
<tr>
<td>excludeSpanID</td>
<td>String</td>
<td>Any span to exclude.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
var x = new GlideSchedule();
x.load('08fcd0830a0a0b2600079f56b1adb9ae');
```

Scoped GlideSchedule - setTimeZone(String timeZone)
Sets the timezone for the current schedule.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeZone</td>
<td>String</td>
<td>The timezone.</td>
</tr>
</tbody>
</table>
This example sets the timezone for the schedule to US/Pacific.

```javascript
var schedule = new GlideSchedule();
schedule.setTimeZone('US/Pacific');
```

**Scoped GlideSchedule - whenNext(GlideDateTime time, String timeZone)**

Determines how much time (in milliseconds) until start time of the next schedule item.

This function is intended to be called when the GlideSchedule object (cmn_schedule table) is not currently in the schedule window. The whenNext() call returns duration (in ms) until the GlideSchedule object is within the schedule. This function does not return a meaningful value if called when the GlideSchedule object is within the schedule.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time</td>
<td>GlideDateTime</td>
<td>Time to be evaluated</td>
</tr>
<tr>
<td>timeZone</td>
<td>String</td>
<td>Timezone</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of milliseconds until the start time of the next schedule item. Returns -1 if never.</td>
</tr>
</tbody>
</table>

```javascript
var startDate = new GlideDateTime('2014-10-25 08:00:00');
var glideSchedule = new GlideSchedule('08fcd0830a0a0b2600079f56b1ad9ae', 'UTC');
gs.info(glideSchedule.whenNext(startDate));
```

Output:

172800000
testScript();

function testScript() {
var now = new GlideDateTime(); //current date and time
var sched = new GlideSchedule("<sys_id>"); // Use a cmn_schedule sys_id
if (sched.isInSchedule(now)) {
    gs.info('We are in an active schedule window so whenNext() is not helpful');
} else {
    gs.info('Not currently in schedule so call whenNext()');
    var msUntilNext = sched.whenNext(new GlideDateTime(), 'US/Pacific');
    gs.info('Next schedule starts in '+msUntilNext+' milliseconds');
}
} // Output [schedule inactive]:
  \ *** Script: Not currently in schedule so call whenNext()
  \ *** Script: Next schedule starts in -1 milliseconds

Output:

[Scheduled for future] *** Script: Not currently in schedule *** Script: Next schedule starts in 332894000 milliseconds

**GlideScriptableInputStream - Scoped, Global**

A GlideScriptableInputStream object cannot be instantiated directly, but is used as an opaque object which is used to connect an input stream from GlideSysAttachment.getContentStream() with other streaming APIs, such as GlideTextReader, GlideDigest, and XMLDocument2.

See the scoped GlideSysAttachment API for methods that return a GlideScriptableInputStream object. The scoped GlideTextReader constructor requires a GlideScriptableInputStream object as an input parameter.

**GlideScriptedProcessor - Scoped**

ServiceNow processors are equivalent to Java servlets.

Processors provide a customizable URL endpoint that can execute arbitrary server-side JavaScript code and produce output such as TEXT, JSON, or HTML. The ScopedGlideScriptedProcessor APIs are used in processor scripts to access the processor (servlet) capabilities. There are no constructors for the ScopedGlideScriptedProcessor APIs. The methods are called using the global variable g_processor.

A useful global variable, g_target, is available in processor scripts. It contains the table name extracted from the URL.
The URL to a processor has the format: https://<instance name.servicenow.com>/
<path endpoint>.do?<parameter endpoint>=<value> where the path endpoint and
parameter endpoint are defined on the processor form.

Scoped GlideScriptedProcessor - redirect(String url)
Redirects to the specified URL.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>Destination URL</td>
</tr>
</tbody>
</table>

//Do whatever processing you need and redirect to the homepage
g_processor.redirect("/navpage.do")

Scoped GlideScriptedProcessor - writeJSON(Object o)
Encodes an object as a JSON string and writes it to the current URL.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>o</td>
<td>Object</td>
<td>The object to encode to a JSON string.</td>
</tr>
</tbody>
</table>

var map = {"key1":"value1","key2":"value2"};
g_processor.writeJSON(map);
Scoped GlideScriptedProcessor - writeOutput(String s)
Writes the specified string to the current URL.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>String</td>
<td>The string to write.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var name = g_request.getParameter("name");
g_processor.writeOutput("Hello " + name);
```

Scoped GlideScriptedProcessor - writeOutput(String contentType, String s)
Writes the specified string to the current URL in the specified character-encoding.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentType</td>
<td>String</td>
<td>Sets the content type of the response sent to the client, if the response has not been committed, and may include a character-encoding specification.</td>
</tr>
<tr>
<td>s</td>
<td>String</td>
<td>The string to write.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var name = g_request.getParameter("name");
g_processor.writeOutput("text/plain", "Hello " + name);
```
GlideSecureRandomUtil - Scoped

The scoped GlideSecureRandomUtil API provides methods for generating integers, long values, and strings.

There is no constructor for this class. Methods are accessed through the static object GlideSecureRandomUtil. The GlideSecureRandomUtil class is available in both global and scoped applications.

Scoped GlideSecureRandomUtil - getSecureRandomInt()

Generates a pseudo-random integer.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The pseudo-randomly generated integer.</td>
</tr>
</tbody>
</table>

```java
gs.info(GlideSecureRandomUtil.getSecureRandomInt());
```

Output:

1976146969

Scoped GlideSecureRandomUtil - getSecureRandomIntBound(Number bound)

Generates a pseudo-random integer between 0 (inclusive) and the bound (exclusive) value that you pass into the method.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bound</td>
<td>Number</td>
<td>The bound value.</td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>------------------------------------------------------------------------</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td>Number</td>
<td>The pseudo-randomly generated integer.</td>
<td></td>
</tr>
</tbody>
</table>

```
gs.info(GlideSecureRandomUtil.getSecureRandomIntBound(100));
```

Output:

55

**Scoped GlideSecureRandomUtil - getSecureRandomLong()**

Generates pseudo-random long value.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>Number</td>
</tr>
</tbody>
</table>

```
gs.info(GlideSecureRandomUtil.getSecureRandomLong());
```

Output:

792836514424092500

**Scoped GlideSecureRandomUtil - getSecureRandomString(Number length)**

Generates a random alpha-numeric String with the specified length.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>length</td>
<td>Number</td>
<td>The length of the string in number of characters.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The randomly generated string.</td>
</tr>
</tbody>
</table>

```java
gs.info(GlideSecureRandomUtil.getSecureRandomString(12));
```

Output:

```
1XzVI0sLfvIT
```

GlideSecurityUtils- Scoped, Global

Provides methods to work with URLs.

Access these methods using the static object GlideSecurityUtils. This class is available in scoped and global scripts.

GlideSecurityUtils - cleanURL(String url)

Removes suspicious encoding to prevent reflected or DOM based cross site scripting.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>The URL to be checked.</td>
</tr>
</tbody>
</table>

```java
myurl='javascript%3Aalert(1)';
var clean=GlideSecurityUtils.cleanURL(myurl);
gs.info(clean);
```

Output: null

GlideSecurityUtils - enforceRelativeURL(String url)

Removes the domain address from the URL, which leaves the page name and parameters.
### GlideSecurityUtils - `enforceRelativeURL(String url)`

**Description**

The URL to be turned into a relative URL.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>The URL to be turned into a relative URL.</td>
</tr>
</tbody>
</table>

```java
myurl='http://evildomain.com/test.do';
relativeURL=GlideSecurityUtils.enforceRelativeURL(myurl);
gs.info(relativeURL);
```

Output: test.do

### GlideSecurityUtils - `escapeScript(String script)`

**Description**

Add escape characters to a script to prevent cross-site scripting.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>script</td>
<td>String</td>
<td>The script to have escape characters added.</td>
</tr>
</tbody>
</table>

```java
theScript="<script> alert(1)</script>";
var escapedScript=GlideSecurityUtils.escapeScript(theScript);
gs.info(escapedScript);
```

Output: `&lt;script&gt; alert(1)&lt;/script&gt;`

### GlideSecurityUtils - `isURLWhiteListed(String url)`

**Description**

Check the specified URL against the system defined allow list.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>script</td>
<td>String</td>
<td>The script to have escape characters added.</td>
</tr>
</tbody>
</table>

```java
theScript="<script> alert(1)</script>";
var escapedScript=GlideSecurityUtils.escapeScript(theScript);
gs.info(escapedScript);
```

Output: `&lt;script&gt; alert(1)&lt;/script&gt;`
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>The URL to be checked against the URL allow list.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if the specified URL is in the allow list.</td>
</tr>
</tbody>
</table>

```java
myURL="http://evil.com/badscript.do";
isWhitelisted=GlideSecurityUtils.isURLWhiteListed(myURL);
gs.info(isWhitelisted);
```

Output: false

### GlideServletRequest - Scoped

The GlideServletRequest API is used in processor scripts.

ServiceNow processors are equivalent to Java servlets. Processors provide a customizable URL endpoint that can execute arbitrary server-side JavaScript code and produce output such as TEXT, JSON, or HTML. The GlideServletRequest API is used in processor scripts to access the HttpServletRequest object. The GlideServletRequest object provides a subset of the HttpServletRequest APIs. The methods are called using the global variable `g_request`.

A useful global variable, `g_target`, is available in processor scripts. It contains the table name extracted from the URL.

The URL to a processor has the format: `https://<instance name.servicenow.com>/<path endpoint>.do?<parameter endpoint>=<value>` where the path endpoint and parameter endpoint are defined on the processor form.

### Scoped GlideServletRequest - getContentType()

Returns the MIME type of the body of the request.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The content type, returns null if the content type is not known.</td>
</tr>
</tbody>
</table>

```javascript
var contentType = g_request.getContentType();
```

**Scoped GlideServletRequest - getHeader(String name)**

Returns the header value.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the header to be retrieved.</td>
</tr>
</tbody>
</table>

```javascript
var headerValue = g_request.getHeader("host");
```

Output:

demonightlyus.service-now.com

**Scoped GlideServletRequest - getHeaderNames()**

Returns a comma-separated list of header names.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A comma-separated list of header names.</td>
</tr>
</tbody>
</table>
var headerList = g_request.getHeaderNames();

Output:

host, connection, cache-control, authorization, accept, user-agent, accept-encoding, accept-language,
cookie, x-forwarded-proto, x-forwarded-host, x-forwarded-for

Scoped GlideServletRequest - getHeaders(String name)

Returns the header values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Names of the headers to be retrieved.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The header values.</td>
</tr>
</tbody>
</table>

var headerValue = g_request.getHeaders("host");

Output:

demonightlyus.service-now.com

Scoped GlideServletRequest - getParameter(String name)

Returns the value of the parameter contained in the request URL.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the parameter to be retrieved. This can be the parameter endpoint from the processor form.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Strings</td>
<td>The parameter value. Returns null if the parameter is not found.</td>
</tr>
</tbody>
</table>
var name = g_request.getParameter("x_snc_custom_x_snc_name");

**Scoped GlideServletRequest - getParameterNames()**

Returns an enumeration list of URL parameters that were used in the request URI.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Java enumerator object list of URL parameters used in the HTTP request URI.</td>
</tr>
</tbody>
</table>

var paramList = g_request.getParameterNames();

**Scoped GlideServletRequest - getQueryString()**

Returns the query string from the request.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The query string.</td>
</tr>
</tbody>
</table>

The code snippet is:

```javascript
var daString = g_request.getQueryString();
g_processor.writeOutput("The query string is: "+ daString);
```

Output: The request URL is: https://demonightlycloudedge.service-now.com/x_custom_app_customApp.do?x_custom_app_name=George&bell=rung
The query string is: x_custom_app_name=George&bell-rung

**GlideServletResponse - Scoped**

The **ScopedGlideServletResponse** API is used in processor scripts.

ServiceNow processors are equivalent to Java servlets. Processors provide a customizable URL endpoint that can execute arbitrary server-side JavaScript code and produce output such as TEXT, JSON, or HTML. The **ScopedGlideServletResponse** API is used in processor scripts to access the **HttpServletResponse** object. The **ScopedGlideServletResponse** object provides a subset of the **HttpServletResponse** APIs. The methods are called using the global variable `g_response`.

A useful global variable, `g_target`, is available in processor scripts. It contains the table name extracted from the URL.

The URL to a processor has the format: `https://<instance name.servicenow.com>/<path endpoint>.do?<parameter endpoint>=<value>` where the path endpoint and parameter endpoint are defined on the processor form.

**Scoped GlideServletResponse - sendRedirect(String location)**

Sends a temporary redirect to the client.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>location</td>
<td>String</td>
<td>The URL to receive the response.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Scoped GlideServletResponse - setContentType(String type)**

Sets the MIME type of the response

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>The MIME type.</td>
</tr>
</tbody>
</table>
void g_response.setContentType('text/html;charset=UTF-8');

Scoped GlideServletResponse - setHeader(String key, String value)
Sets a response header to the specified value.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Specifies the header.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The value to be assigned to the header. If the header exists, it is overwritten.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

void g_response.setHeader("host", "instance.service-now.com");

Scoped GlideServletResponse - setStatus(Number status)
Sets the status code for the response.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>Number</td>
<td>The status to be set.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
// set the status to okay
g_response.setStatus(200);

**GlideSession - Global**

The GlideSession API allows you to find information about the current session.

### GlideSession - clearClientData(String paramName)

Clears a session client value previously set with `putClientData()`.

This method is used in a client script to clear data values that were set by a server script using the `putClientData()` method.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paramName</td>
<td>String</td>
<td>Name of the client data to clear.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var session = gs.getSession();
session.putClientData('custName', 'Harry');
var clientData = session.getClientData('custName');
gs.info(clientData);

session.clearClientData('custName');
clientData = session.getClientData('custName');
gs.info(clientData);
```

**Output:**

<table>
<thead>
<tr>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Harry</td>
</tr>
<tr>
<td>null</td>
</tr>
</tbody>
</table>

### GlideSession - getClientData(String paramName)

Returns a session client value previously set with `putClientData()`.
This method is used in a client script to retrieve data values that were set by a server script that used the `putClientData()` method.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paramName</td>
<td>String</td>
<td>Name of the client data to retrieve.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The client data as a string.</td>
</tr>
</tbody>
</table>

```javascript
var session = gs.getSession();
session.putClientData('test1', 'Harry');
var clientData = session.getClientData('test1');
gs.info(clientData);
```

**Output:**

```
Harry
```

### Scoped equivalent

To use the `getClientData()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSession - getClientData(String paramName)**.

### GlideSession - getLanguage()

Gets the session's language code.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The session's language code.</td>
</tr>
</tbody>
</table>
var session = gs.getSession();
var language = session.getLanguage();
gs.info(language);

Output:

en

Scoped equivalent

To use the `getLanguage()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSession - getLanguage()`.

**GlideSession - getRoles()**

Gets a list of roles for the current user.

The list of roles does not reflect any changes made during the current user session. To get the updated list of roles, the user must log out and log back in.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

`gs.info(gs.getSession().getRoles());`

Output:

admin,hr_fulfiller,itsa_fulfiller,security_admin

**GlideSession - getTimeZoneName()**

Gets the name of the session's time zone.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The name of the session’s time zone.</td>
</tr>
</tbody>
</table>

```javascript
var session = gs.getSession();
var zoneName = session.getTimeZoneName();
gs.info(zoneName);
```

Output:

US/Pacific

Scoped equivalent

To use the `getTimeZoneName()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSession - getTimeZoneName()`.

GlideSession - isInteractive()

Determines if the current session is interactive.

An interactive session is one that involves an end-user interacting with a user interface that then retrieves information from a server. An example of this type of session is when a user logs in using the log-in screen or uses a form to query a data store. A non-interactive session is one that only involves programmatic interaction with a server such as a SOAP request to retrieve data.
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the session is interactive.</td>
</tr>
</tbody>
</table>

⚠️ **Note:** The `isInteractive()` method will always return a false value for all user sessions using the classic or current mobile applications.

```javascript
var interActive = gs.getSession().isInteractive();
gs.info(interActive);
```

Output:

false

**Scoped equivalent**

To use the `isInteractive()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSession - isInteractive()`.

### GlideSession - isLoggedIn()

Determines if the current user is currently logged in.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the current user is logged in.</td>
</tr>
</tbody>
</table>

```javascript
var session = gs.getSession();
var loggedIn = session isLoggedIn();
gs.info(loggedIn);
```

Output:

true
Scoped equivalent

To use the isLoggedIn() method in a scoped application, use the corresponding scoped method: Scoped GlideSession - isLoggedIn().

GlideSession - putClientData(String paramName, String paramValue)

Sets a session client value that can be retrieved with getClientData(). This method is used in a server side script that runs when a form is created.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paramName</td>
<td>String</td>
<td>Name of the client parameter to set.</td>
</tr>
<tr>
<td>paramValue</td>
<td>String</td>
<td>Parameter value.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var session = gs.getSession();
session.putClientData('test1', 'Harry');
var clientData = session.getClientData('test1');
gs.info(clientData);
```

Output:

Harry

Scoped equivalent

To use the putClientData() method in a scoped application, use the corresponding scoped method: Scoped GlideSession - putClientData(String paramName, String paramValue).

GlideSession - Scoped

The scoped GlideSession API provides a way to find information about the current session.

There are no constructors for creating an instance of a scoped GlideSession object. Instead, use the getSession() method of the scoped GlideSystem API.
Scoped GlideSession - getClientData(String paramName)
Retrieves a session client value previously set with putClientData().
Use this method to retrieve data values that were set using the putClientData() method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paramName</td>
<td>String</td>
<td>Name of the client data to retrieve.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The client data as a string.</td>
</tr>
</tbody>
</table>

```javascript
var session = gs.getSession();
session.putClientData('test1', 'Harry');
var clientData = session.getClientData('test1');
gs.info(clientData);
```

Output:

Harry

Scoped GlideSession - getClientIP()
Returns the client IP address.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The IP address.</td>
</tr>
</tbody>
</table>
var session = gs.getSession();
var addr = session.getClientIP();
gs.info(addr);

Output:
50.59.164.97

Scoped GlideSession - getCurrentApplicationId()

Returns the application currently selected in the application picker.

This method requires admin privileges.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The currently selected application.</td>
</tr>
</tbody>
</table>

var session = gs.getSession();
var appID = session.getCurrentApplicationId();
gs.info(appID);

Output:
ce05b9f32b840200c5244f74b4da1501

Scoped GlideSession - getCurrentDomainID()

Returns the sys_id of the current domain for the logged-in user session.

The identifier that is returned depends on the domain type and the instantiation of that domain.

- If the user is configured in the global domain, and does not use the domain picker to switch domains, the method returns null.
- If the user uses the domain picker to switch to the global domain, the method returns the string "global".
- For all other domains, the method returns the sys_id of that domain.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the session domain of the current logged-in user. This is the same information that appears in the domain picker.</td>
</tr>
</tbody>
</table>

This example shows the current sys_email record's domain being set to the user's session domain, if the user domain is global or null.

```javascript
// Set domain based on parent record's domain
setDomain();

// If the domain is global, set to user's domain
if (current.sys_domain == 'global' || current.sys_domain.nil())
    current.sys_domain = gs.getSession().getCurrentDomainID();

function setDomain()
{
    if (current.target_table.nil())
        return;

    var d = new GlideRecord(current.target_table);
    if (!d.isValid())
        return;

    if (!d.get('sys_id', current.instance))
        return;

    if (typeof(d.sys_domain) == 'object')
        current.sys_domain = d.sys_domain;

    Scoped GlideSession - getLanguage()
Returns the session's language code.
```
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The session's language code.</td>
</tr>
</tbody>
</table>

```javascript
var session = gs.getSession();
var language = session.getLanguage();
gs.info(language);
```

Output:
```
en
```

Scoped GlideSession - getSessionToken()

Returns the session token.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The session token.</td>
</tr>
</tbody>
</table>

```javascript
var session = gs.getSession();
var token = session.getSessionToken();
gs.info(token);
```

Output:
```
4284b5372b840200c5244f74b4da15f2c3476cf7fcb6572afa4ef9d5e6d307a5fd9e1da7
```
Scoped GlideSession - getTimeZoneName()

Returns the name of the session's time zone.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The name of the session's time zone.</td>
</tr>
</tbody>
</table>

```js
var session = gs.getSession();
var zoneName = session.getTimeZoneName();
gs.info(zoneName);
```

Output:

US/Pacific

 Scoped GlideSession - getUrlOnStack()

Returns the URL on the stack. Returns null if the stack is empty.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The URL. Returns null if the stack is empty.</td>
</tr>
</tbody>
</table>

```js
var session = gs.getSession();
var URL = session.getUrlOnStack();
gs.info(URL);
```

Output: line breaks added for clarity.
Scoped GlideSession - isImpersonating()

Returns true if the user is impersonating another user.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Returns true if the user is impersonating another user; otherwise, returns false.</td>
</tr>
</tbody>
</table>

```javascript
var isImpersonator = gs.getSession().isImpersonating();
gs.info(isImpersonator);
```

Scoped GlideSession - isInteractive()

Returns true if the session is interactive.

An interactive session is one that involves an end-user interacting with a user interface that then retrieves information from a server. An example of this type of session is when a user logs in using the log-in screen or uses a form to query a data store. A non-interactive session is one that only involves programmatic interaction with a server such as a SOAP request to retrieve data.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the session is interactive.</td>
</tr>
</tbody>
</table>
var interActive = gs.getSession().isInteractive();
gs.info(interActive);

Scoped GlideSession - isLoggedIn()
Returns true if the user is logged in.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the user is logged in.</td>
</tr>
</tbody>
</table>

var session = gs.getSession();
var loggedIn = session.isLoggedIn();
gs.info(loggedIn);

Output:

true

Scoped GlideSession - putClientData(String paramName, String paramValue)
Sets a session client value that can be retrieved with getClientData(). This method is used in a server side script that runs when a form is created.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>paramName</td>
<td>String</td>
<td>Name of the client data to set.</td>
</tr>
<tr>
<td>paramValue</td>
<td>String</td>
<td>Value of the client data.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
var session = gs.getSession();
session.putClientData('test1', 'Harry');
var clientData = session.getClientData('test1');
gs.info(clientData);

Output:
Harry

**GlideSPScriptable - Scoped**

Interact with data and perform record operations in Service Portal widgets. You access GlideSPScriptable methods by using the global `$sp` object.

 Scoped GlideSPScriptable - `canReadRecord(GlideRecord now_GR)`

Returns true if the user can read the specified GlideRecord.

If the record type is `kb_knowledge`, `sc_cat_item`, or `sc_category`, the method checks if the user can view the item.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>The GlideRecord to check.</td>
</tr>
</tbody>
</table>

Server script

```javascript
//Server script
data.items = [];
data.userName = gs.getUserDisplayName();
var now_GR = new GlideRecord("sc_cat_item");
now_GR.query();
while(now_GR.next() && data.items.length < 10) {
    if ($sp.canReadRecord(now_GR)) {
        data.items.push(now_GR.getDisplayValue("name"));
    }
}
```
//HTML template
<div class="panel panel-default">
    <div class="panel-heading">Hi, {{c.data.userName}}!</div>
    <div class="panel-body">
        Here are some things you can order:
        <ul><li ng-repeat="item in c.data.items">{{item}}</li></ul>
    </div>
</div>

Scoped GlideSPScriptable - canReadRecord(String table, String sysId)

Returns true if the user can read the specified GlideRecord.

If the record type is kb_knowledge, sc_cat_item, or sc_category, the method checks if the user can view the item.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>Name of the table to query.</td>
</tr>
<tr>
<td>sysId</td>
<td>String</td>
<td>Sys_id of the record to query.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the record is valid and readable.</td>
</tr>
</tbody>
</table>

Scoped GlideSPScriptable - canSeePage(String pageID)

Returns true if the currently logged in user has permission to view the specified page.

The system determines permission using roles and user criteria. For more information, see Configure page security by role and User criteria for Service Portal.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageID</td>
<td>String</td>
<td>Page ID from the Pages [sp_page] table.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the currently logged in user has permissions to view the specified page. Values include:</td>
</tr>
<tr>
<td></td>
<td>• true: The user can view the page.</td>
</tr>
<tr>
<td></td>
<td>• false: Either the user cannot view the page, the given pageID is not valid, or the user is not logged in.</td>
</tr>
</tbody>
</table>

This example adds a condition to the Knowledge menu item in the SP Header Menu to only show the menu item to users who have permission to view the kb_view2 page.

GlideSPScriptable.canSeePage("kb_view2")

Scoped GlideSPScriptable - `getCatalogItem(String sysId)`

Returns a model and view model for a `sc_cat_item` or `sc_cat_item_guide`.

This method is deprecated. Use the `getCatalogItem(String sysId, Boolean isOrdering)` method instead. This method calls the `getCatalogItem(String sysId, Boolean isOrdering)` method with the `isOrdering` parameter set to false, which means that write roles security checking is done.

This method is a quick way to get the data necessary to render and order a catalog item using `<sp-model />`. If you just need to get a catalog item to show its picture or name, use GlideRecord to query the `sc_cat_item` table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysId</td>
<td>String</td>
<td>The sys_id of the catalog item (<code>sc_cat_item</code>) or order guide (<code>sc_cat_item_guide</code>).</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object containing the catalog item variable model, view, sections, pricing, and client scripts.</td>
</tr>
</tbody>
</table>
// Server script
(function() {
    var sys_id = $sp.getParameter("sys_id")
    data.catItem = $sp.getCatalogItem(sys_id);
})();

// Client script
function($http, spUtil) {
    var c = this;
    var submitting = false;
    c.getIt = function() {
        if (submitting) return;
        $http.post(spUtil.getURL('sc_cat_item'), c.data.catItem).success(function(response)
        {
            if (response.answer) {
                c.req = response.answer;
                c.req.page = c.req.table == 'sc_request' ? 'sc_request' : 'ticket';
            }
        });
    }
}

//SCSS
.img-bg {
    padding: 5px;
    background-color: $brand-primary;
}
.img-responsive {
    margin: 0 auto;
}
.cat-icon {
    display: block;
    margin: -40px auto 0;
}

// HTML template
<div class="col-sm-4">
    <div class="panel panel-default">
        <div class="img-bg">
            <img ng-src="{{::data.catItem.picture}}" class="img-responsive" />
            </div>
    </div>
</div>
**Scoped GlideSPScriptable - getCatalogItem(String sysId, Boolean isOrdering)**

Returns a model and view model for a `sc_cat_item` or `sc_cat_item_guide`.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysId</td>
<td>String</td>
<td>The sys_id of the catalog item (<code>sc_cat_item</code>) or order guide (<code>sc_cat_item_guide</code>).</td>
</tr>
</tbody>
</table>
| isOrdering | Boolean | When true, uses create roles security check. When false, uses write roles security check.  
When users are ordering an item or have it in their cart, check using the create roles.  
If users are not ordering, for example, somebody is looking at a requested item to see the variables associated with that item, then check using the write roles. |
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object containing the catalog item variable model, view, sections, pricing, and client scripts.</td>
</tr>
</tbody>
</table>

**Scoped GlideSPScriptable - getDisplayValue(String fieldName)**

Returns the display value of the specified field (if it exists and has a value) from either the widget's sp_instance or the sp_portal record.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The display value from either the sp_instance or sp_portal record.</td>
</tr>
</tbody>
</table>

```javascript
//Server script
(function() {
    data.title = $sp.getDisplayValue("title");
    data.catalog = $sp.getDisplayValue("sc_catalog");
})();

//HTML template
<div>
    <h1>sp_instance.title: {{::data.title}}</h1>
    <h1>sp_portal.sc_catalog: {{::data.catalog}}</h1>
</div>
```

**Scoped GlideSPScriptable - getField(GlideRecord now_GR, String fieldName)**

Returns information about the specified field in the specified GlideRecord.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>The GlideRecord to check</td>
</tr>
<tr>
<td>fieldName</td>
<td>String</td>
<td>The field to find information for</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object containing the field’s label, value, <code>displayValue</code>, and type. Returns null if the GlideRecord of field name are not valid, or if the field is not readable.</td>
</tr>
</tbody>
</table>

**Scoped GlideSPScriptable - `getFields(GlideRecord now_GR, String fieldNames)`**

Checks the specified list of field names, and returns an array of valid field names.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>The GlideRecord to check</td>
</tr>
<tr>
<td>fieldNames</td>
<td>String</td>
<td>A comma separated list of field names.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of valid fields.</td>
</tr>
</tbody>
</table>

**Scoped GlideSPScriptable - `getFieldsObject(GlideRecord now_GR, String fieldNames)`**

Checks the specified list of field names and returns an object of valid field names.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>The GlideRecord to check</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fieldName</td>
<td>String</td>
<td>A comma separated list of field names.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object containing valid field names.</td>
</tr>
</tbody>
</table>

Scoped GlideSPScriptable - getForm(String tableName, String sysId)

Return the form.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The name of the table</td>
</tr>
<tr>
<td>sysId</td>
<td>String</td>
<td>The form’s sys_id</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The form</td>
</tr>
</tbody>
</table>

Scoped GlideSPScriptable - getKBCategoryArticles(String sys_id, Number limit)

Returns KB articles in the specified category and its subcategories.

To avoid performance issues, do not use this method to return articles in large categories or articles with inline images. Instead, use getKBArticleSummaries().

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysId</td>
<td>String</td>
<td>Sys_id of the KB article category.</td>
</tr>
<tr>
<td>limit</td>
<td>Number</td>
<td>Maximum number of KB articles returned.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>The articles within the category and its subcategories with:</td>
</tr>
<tr>
<td></td>
<td>• A workflow_state of published.</td>
</tr>
<tr>
<td></td>
<td>• A valid_to date greater than or equal to the current date.</td>
</tr>
</tbody>
</table>

//Server script
(function() {
    data.kbs = $sp.getKBCategoryArticles("0ac1bf8bff0221009b20ffffffec", 5);
})();

//HTML template
<div>
articles: {{::data.kbs}}
</div>

Scoped GlideSPScriptable - getKBCategoryArticleSummaries(String sys_id, Number limit, Number maxChars)

Returns Knowledge Base article summaries in the specified category and its subcategories.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>String</td>
<td>Sys_id of the KB article category.</td>
</tr>
<tr>
<td>limit</td>
<td>Number</td>
<td>Maximum number of KB articles returned.</td>
</tr>
<tr>
<td>maxChars</td>
<td>Number</td>
<td>Maximum number of characters to return from the article text. For full article text, set the value to -1.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>The articles within the category and its subcategories with:</td>
</tr>
<tr>
<td></td>
<td>• A workflow_state of published.</td>
</tr>
<tr>
<td></td>
<td>• A valid_to date greater than or equal to the current date.</td>
</tr>
</tbody>
</table>
// Server script
(function() {
    data.summary = $sp.getKBCategoryArticleSummaries("0ac1bf8bff0221009b20ff0fffffffec", 5, 200);
})();

// HTML template
<div>
    articles: {{::data.summary}}
</div>

Scoped GlideSPScriptable - getKBCount(String sys_id)

Returns the number of articles in the defined Knowledge Base.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>String</td>
<td>Sys_id of a Knowledge Base record.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>Number of knowledge articles in the defined Knowledge Base with:</td>
</tr>
<tr>
<td></td>
<td>• A workflow_state of published.</td>
</tr>
<tr>
<td></td>
<td>• A valid_to date greater than or equal to the current date.</td>
</tr>
</tbody>
</table>

// Server script
(function() {
    data.count = $sp.getKBCount("a7e8a78bff0221009b20fffffff17");
})();

// HTML template
<div>
    articles: {{::data.count}}
</div>

Scoped GlideSPScriptable - getListColumns(String tableName, String view)

Returns a list of the specified table's columns in the specified view.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table</td>
</tr>
<tr>
<td>view</td>
<td>String</td>
<td>The view by which to filter the columns</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>An object containing the column names.</td>
</tr>
</tbody>
</table>

Scoped GlideSPScriptable - getMenuItems(String sysId)

Returns an array of menu items for the specified instance.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysId</td>
<td>String</td>
<td>sysId of the instance</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>Menu items for the specified instance</td>
</tr>
</tbody>
</table>

Scoped GlideSPScriptable - getMenuHREF(GlideRecord page)

Returns the (?id=) portion of the URL based on the sp_menu type.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>page</td>
<td>GlideRecord</td>
<td>The page</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The href portion of the URL.</td>
</tr>
</tbody>
</table>
Scoped GlideSPScriptable - getParameter(String name)

Returns the value of the specified parameter.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name of the key from the query string or post body.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Returns the specified parameter as an object. Returns null if there is no request, JSON request, or widget.</td>
</tr>
</tbody>
</table>

Scoped GlideSPScriptable - getPortalRecord()

Returns the portal record from the Service Portals [sp_portal] table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>The portal record for the current portal from the Service Portals [sp_portal] table.</td>
</tr>
</tbody>
</table>

```
//Server script
(function() {
    var portalGr = $sp.getPortalRecord();
    data.logo = portalGr.getDisplayValue("logo");
    data.homepage = portalGr.getDisplayValue("homepage.id");
})();

//HTML template
<div>
    <img ng-src="{{c.data.logo}}" />
```
Scoped GlideSPScriptable - getRecord(String table, String sys_id)

If parameters are provided, returns the GlideRecord identified by the provided table and Sys ID. If no parameters are provided, returns the record identified by the current URL.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>Optional. The table of the record to return. If no parameters are included, returns the table and Sys ID identified by the current URL.</td>
</tr>
<tr>
<td>sys_id</td>
<td>String</td>
<td>Optional. The Sys ID of the record to return. If no parameters are included, returns the record identified by the current URL.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>If parameters are provided, returns the record identified by the provided table and Sys ID.</td>
</tr>
<tr>
<td></td>
<td>If no parameters are provided, returns the record identified by the current URL.</td>
</tr>
<tr>
<td></td>
<td>Returns null if the widget is embedded by another widget, or if the record for the provided parameters is not found.</td>
</tr>
</tbody>
</table>

//Server script
(function(){
  var now_GR = $sp.getRecord();
data.tableLabel = now_GR.getLabel();
})();

//HTML template
<div class="panel-heading">
  <h4 class="panel-title">${{{data.tableLabel}} details}</h4>
</div>
Scoped GlideSPScriptable - `getRecordDisplayValues(Object data, GlideRecord from, String names)`

Copies display values for the specified fields into the data parameter.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>Object</td>
<td>The display values for the specified fields are copied to this object.</td>
</tr>
<tr>
<td>from</td>
<td>GlideRecord</td>
<td>The GlideRecord to process.</td>
</tr>
<tr>
<td>names</td>
<td>String</td>
<td>A comma-separated list of field names.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Scoped GlideSPScriptable - `getRecordElements(Object data, GlideRecord from, String names)`

For the specified fields, copies the element's name, display value, and value into the data parameter.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>Object</td>
<td>The element's name, display value, and value for the specified fields are copied to this object.</td>
</tr>
<tr>
<td>from</td>
<td>GlideRecord</td>
<td>The GlideRecord to process.</td>
</tr>
<tr>
<td>names</td>
<td>String</td>
<td>A comma-separated list of field names.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
Scoped GlideSPScriptable - getRecordValues(Object data, GlideRecord from, String names)

Copies values for the specified field names from the GlideRecord into the data parameter.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>Object</td>
<td>The value for the specified fields are copied to this object.</td>
</tr>
<tr>
<td>from</td>
<td>GlideRecord</td>
<td>The GlideRecord to process.</td>
</tr>
<tr>
<td>names</td>
<td>String</td>
<td>A comma-separated list of field names.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Scoped GlideSPScriptable - getRecordVariables(GlideRecord now_GR, Boolean includeNilResponses)

Returns Service Catalog variables associated with a record in String format.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>The record to retrieve Service Catalog variables for. Must be a record with Service Catalog variables defined, such as a requested item [sc_req_item] record or an incident submitted through a record producer.</td>
</tr>
<tr>
<td>includeNilResponses</td>
<td>Boolean</td>
<td>Optional. If true, the API includes variables with no user-defined value.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Service Catalog variables associated with the record.</td>
</tr>
</tbody>
</table>
//Server script
(function() {
    var itemsGR = new GlideRecord("sc_req_item");
    itemsGR.get('585d1bc44f4f13008a959a211310c77d');

    data.scVars = $sp.getRecordVariables(itemsGR);

})();

//HTML template
<div>
    Requested item variables: {{::data.scVars}}
</div>

Output:

Requested item variables: [
    {
        "display_value":"MetroPCS",
        "name":"carrier",
        "visible_summary":true,
        "id":"585d1bc44f4f13008a959a211310c77c",
        "label":"Allocated carrier",
        "type":"5",
        "value":"metropcs",
        "visible_standalone":true,
        "visible_guide":true
    },
    {
        "display_value":"Unlimited",
        "name":"data_plan",
        "visible_summary":true,
        "id":"d05d1bc44f4f13008a959a211310c77c",
        "label":"Monthly data allowance",
        "type":"5",
        "value":"unlimited",
        "visible_standalone":true,
        "visible_guide":true
    },
    {
        "display_value":"12 Months",
        "name":"duration",
        "visible_summary":true,
        "id":"d85d1bc44f4f13008a959a211310c77c",
        "label":null,
        "type":null,
        "value":null,
        "visible_standalone":true,
        "visible_guide":true
    }
]
Scoped GlideSPScriptable - getRecordVariablesArray(GlideRecord now_GR, Boolean includeNilResponses)

Returns an array of Service Catalog variables associated with a record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>The record to retrieve Service Catalog variables for. Must be a record with Service Catalog variables defined, such as a requested item [sc_req_item] record or an incident submitted through a record producer.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>includeNilResponses</td>
<td>Boolean</td>
<td>Optional. If true, the API includes variables with no user-defined value.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Array of Service Catalog variables associated with the record.</td>
</tr>
</tbody>
</table>

//Server script
(function() {
    var itemsGR = new GlideRecord("sc_req_item");
    itemsGR.get('585d1bc44f4f13008a959a211310c77d');

    data.scVars = $sp.getRecordVariablesArray(itemsGR);

});

//HTML template
<div>
    Requested item variables: {{::data.scVars}}
</div>

Output:

Requested item variables: [
    {
        "display_value": "MetroPCS",
        "name": "carrier",
        "visible_summary": true,
        "id": "585d1bc44f4f13008a959a211310c77c",
        "label": "Allocated carrier",
        "type": "5",
        "value": "metropcs",
        "visible_standalone": true,
        "visible_guide": true
    },
    {
        "display_value": "Unlimited",
        "name": "data_plan",
        "visible_summary": true,
    },
]
Scoped GlideSPScriptable - getStream(String table, String sysId)

Gets the activity stream for the specified record. This method works on tables that extend the task table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>String</td>
<td>The table name</td>
</tr>
<tr>
<td>sysId</td>
<td>String</td>
<td>The sys_id of the record</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>If a table extending the task table is specified, contains the display_value, sys_id, short_description,number, entries, user_sys_id, user_full_name, user_login, label, table, and journal_fields properties; otherwise contains the table and sys_id properties.</td>
</tr>
</tbody>
</table>

ℹ️ Note: The user_login property contains the User ID of the current user. The user_sys_id and user_full_name properties reference the creator of the queried record.

Scoped GlideSPScriptable - getUserInitials()

Returns the user's initials.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The user's initials</td>
</tr>
</tbody>
</table>

Scoped GlideSPScriptable - getValue(String name)

Returns the named value of the JSON request, instance, or portal.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the JSON request, instance, or portal.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Value of the specified parameter. Null if the specified entity does not exist or has no such parameter.</td>
</tr>
</tbody>
</table>

//Server script
(function() {
    data.title = $sp.getValue("title");
    data.catalog = $sp.getValue("sc_catalog");
})();

//HTML template
<div>
    <h1>sp_instance.title: {{::data.title}}</h1>
    <h1>sp_portal.sc_catalog: {{::data.catalog}}</h1>
</div>

Scoped GlideSPScriptable - `getValue(Object data, String names)`
Copies values from the request or instance to the data parameter.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>Object</td>
<td>Receives the parameter values.</td>
</tr>
<tr>
<td>names</td>
<td>String</td>
<td>Comma-separated string of field names.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
Scoped GlideSPScriptable - getVariablesArray(Boolean includeNilResponses)

Returns an array of Service Catalog variables associated with the record in the URL.

For example, if the URL includes the parameters
id=form&table=sc_req_item&sys_id=832e9620db4f330083766b984b9619cf, the API returns the variables associated with the given record in the Requested item [sc_req_item] table. Must be a record with Service Catalog variables defined, such as a requested item [sc_req_item] record or an incident submitted through a record producer.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>includeNilResponses</td>
<td>Boolean</td>
<td>Optional. If true, the API includes variables with no user-defined value.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Array of variables associated with the table.</td>
</tr>
</tbody>
</table>

//Server script
(function() {
  data.scVars = $sp.getVariablesArray();
})();

//HTML template
<div>
  Current record variables: {{::data.scVars}}
</div>

Output:

Current record variables: [
  {
    "display_value":"unlimited",
    "name":"data","visible_summary":true,"id":"472e5620db4f330083766b984b96198a",
    "label":"Data",
    "type":"6",
  }
]
Scoped GlideSPScriptable - `getWidget(String sysID, Object options)`

Gets a widget by id or sys_id, executes that widget's server script using the provided options, then returns the widget model.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysID</td>
<td>String</td>
<td>The widget sys_id or widget_id</td>
</tr>
<tr>
<td>options</td>
<td>Object</td>
<td>An object to pass to the widget's server script. Refer to this object as <code>options</code> in your server script.</td>
</tr>
</tbody>
</table>

**Note:** Any options passed into this function will only be available in the embedded widget's server script on the **first execution** of that script. Any subsequent calls into the server script from the embedded widget will not contain the object properties passed in.

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>A widget model to be used with sp-widget.</td>
</tr>
</tbody>
</table>
//Server script
data.myWidget = $sp.getWidget('widget_id', {p1: param1, p2: param2});

//HTML
<sp-widget widget="c.data.myWidget"></sp-widget>

Scoped GlideSPScriptable - mapUrlToSPUrl(String url)
Transforms a URL requesting a list or form in the platform UI into the URL of the corresponding id=list or id=form Service Portal page.

Use this method to perform tasks such as redirecting a user after login to the correct Service Portal page when they request a platform UI form or list URL. Note that the id=list and id=form page targets are not customizable.

Note: Table, sys_id, and sysparm_query values are preserved from the original URL; sysparm_view is not.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>Platform UI URL</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Transformed Service Portal URL. If the passed-in URL does not request a list or a form in the platform UI, a null value is returned.</td>
</tr>
</tbody>
</table>

List example

```java
GlideSPScriptable().mapUrlToSPUrl("http://demo.service-now.com/task_list.do?sysparm_userpref_module=1523b8d4c611227b00be8216ec331b9a&sysparm_query=assigned_to=javascript:getMyAssignments()&sysparm_clear_stack=true")
```

Returns

```
id=list&table=task&filter=assigned_to=javascript:getMyAssignments()&sys_id=&v=
```

Form example

```java
GlideSPScriptable().mapUrlToSPUrl("incident.do?sys_id=12bc12bc12bc12bc12bc12bc12bc")
```
Returns

```plaintext
id=form&table=incident&filter=&sys_id=12bc12bc12bc12bc12bc12bc12bc12bc&v=
```

Scoped GlideSPScriptable - `userCanSeeSearchSourceByCriteria(String searchSourceID)`

Returns true if the current user can see a search source specified by the `searchSourceID`.

Returns true if the user is not restricted by user criteria. For more detail on how user criteria affects Service Portal assets, see [User criteria for Service Portal](#).

ℹ️ **Note:** This method does not evaluate role-based permissions of the search source, and should only be used if User Criteria is enabled.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>searchSourceID</code></td>
<td>String</td>
<td>Sys_id of the search source record.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if current user has read access to the search source.</td>
</tr>
</tbody>
</table>

Scoped GlideSPScriptable - `isUserCriteriaEnabled()`

Returns true if user criteria is enabled.

This method returns true if the Service Portal User Criteria Support plugin (com.glide.service-portal.user-criteria) is active and the Enable use of User Criteria records instead of Roles fields for Service Portal entitlements (glide.service_portal.user_criteria_enabled) system property is set to true.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if user criteria is enabled.</td>
</tr>
</tbody>
</table>

**GlideSPSearchAnalytics - Global**

Generates search analytics from custom ServiceNow search widgets.

By default, the Search Events [sys_search_event] and Search Source Events [sys_search_source_event] tables collect search data from base system search widgets. However, custom search widgets do not benefit from this feature. Use this API in the server script of custom search widgets in global environments to send search data to the search events tables. Generate relevant search suggestions for your users and monitor search analytics to understand what your users are searching for and whether they’re finding what they need.

This API collects the following search data:

- Searched terms
- Rank of clicked items
- Filters used to refine search results
- Table names and record identifiers from the first page of search results
- Search results clicked, including browser and location

Search Suggestions is a Now Platform feature. For more information, see Search Suggestions.

**GlideSPSearchAnalytics - publish(String payload)**

Sends search data to the Search Event [sys_search_event], Search Event per source [sys_search_source_event], and Search Signal Event [sys_search_signal_event] tables for search results, or to the Search Result Clicked [sys_search_result_clicked] and Search Signal Result Event [sys_search_signal_result_event] tables when a user clicks a search result.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>payload</td>
<td>String</td>
<td>JSON payload in String format containing the search data to send to the Search Event [sys_search_event], Search Event per source [sys_search_source_event], and Search Signal</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event [sys_search_signal_event] tables for search results, or to the Search Result Clicked [sys_search_result_clicked] and Search Signal Result Event [sys_search_signal_result_event] tables when a user clicks a search result. Structure the payload as key-value pairs according to the type of search data you would like to collect.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Collect data when the user searches for a term:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>◦ query: String. The query being searched.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>◦ results_per_source: Array. Number of results returned from each search source.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>number_of_results: Number. Number of results returned from the query for the specific search source.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ais_profile: String. Sys_id of the search profile applied to the search. Only applicable for searches made with the AI Search engine.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>search_results: Array. Results returned in the first page of search results.</td>
<td></td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record_id</td>
<td>String</td>
<td>Sys_id of the search result record.</td>
</tr>
<tr>
<td>table_name</td>
<td>String</td>
<td>Name of the table in which the search result record was found.</td>
</tr>
<tr>
<td>refinement_occurred</td>
<td>Boolean</td>
<td>True if the user filtered the search results; otherwise false.</td>
</tr>
</tbody>
</table>

- Collect data when a user refines their search results:
  - query: String. The query being searched.
  - refinement_occurred: Boolean. True if the user filtered the search results; otherwise false.

- Collect the rank of the search result that the user selected.
  - query: String. The query being searched.
  - click_rank: Number. Rank of the item the user selected. For example, if the user clicked the third item in a list of search results, the value is 3.

- Collect information on the search result that the user clicks. Data logs to the Search Result Clicked [sys_search_result_clicked] table.
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>String</td>
<td>The query being searched.</td>
</tr>
<tr>
<td>page_id</td>
<td>String</td>
<td>Sys_id of the page record from the Pages [sp_page] table.</td>
</tr>
<tr>
<td>results_per_source</td>
<td>Array</td>
<td>Number of results returned from each search source.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>source_id</td>
<td>String</td>
<td>Sys_id of the search source record from the Search Sources [sp_search_source] table.</td>
</tr>
<tr>
<td>number_of_results</td>
<td>Number</td>
<td>Number of results returned from the query for the specific search source.</td>
</tr>
<tr>
<td>refinement_occurred</td>
<td>Boolean</td>
<td>True if the user filtered the search results; otherwise false.</td>
</tr>
<tr>
<td>click_rank</td>
<td>Number</td>
<td>Rank of the item the user selected. For example, if the user clicked the third item in a list of search results, the value is 3.</td>
</tr>
<tr>
<td>browser_info</td>
<td>String</td>
<td>Logs browser name, version, and platform.</td>
</tr>
<tr>
<td>location</td>
<td>Float</td>
<td>Logs latitude and longitude coordinates of the user location.</td>
</tr>
<tr>
<td>result_clicked_sys_id</td>
<td>String</td>
<td>Sys_id of the result the user selected.</td>
</tr>
<tr>
<td>label_description</td>
<td>String</td>
<td>Description of the result that the user selected.</td>
</tr>
<tr>
<td>source_table</td>
<td>String</td>
<td>Name of the source table containing the selected result.</td>
</tr>
<tr>
<td>ais_doc_id</td>
<td>String</td>
<td>Underscore-separated name of the source table and sys_id of the result record for each result the user selected. For example, for the result &quot;results&quot; where the user clicked the first result, the value is &quot;results/resultssysid&quot;.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>example, if the user clicked a result from the Knowledge [kb_knowledge] table, the value is of the form kb_knowledge_3020c9b14843210e9db4b5b08b9a712d. Only applicable for searches made with the AI Search engine.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• Collect data when a user searches for a term and collect the rank of the search result that the user clicked:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>◦ query: String. The query being searched.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>◦ results_per_source: Array. Number of results returned from each search source.</td>
<td></td>
<td></td>

<td>String</td>
<td>Underscore-separated name of the source table and sys_id of the result record for each result the user selected. For example, if the user clicked a result from the Knowledge [kb_knowledge] table, the value is of the form kb_knowledge_3020c9b14843210e9db4b5b08b9a712d. Only applicable for searches made with the AI Search engine.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

This example passes direct search data to the search analytics tables.

```javascript
var searchObject = new GlideSPSearchAnalytics();
var payload = {
    'query': 'how do i get a new computer',
    'portal_id': '81b75d3147032100ba13a5554ee4902b',
    'page_id': '87466b63c3223100c8b837659bba8feb',
    'results_per_source': [{
        'source_id': 'bf2c4c15b3a31300e64be12b86a8dcb7',
        'number_of_results': 2,
    }, {
        'source_id': 'c96eb1686721220023c82e08f585efff',
        'number_of_results': 1
    }],
    'refinement': false,
    'search_results': [{
        'record_id': 'KB Article 1',
        'table_name': 'knowledge'
    }, {  
```
This example dynamically collects direct search data from a custom search widget and passes it to the search analytics tables.

```javascript
var directSearchData = searchObject.publish(JSON.stringify(payload));
```

//client script
var payload = {
  query: this.data.query,
  portal_id: this.data.portalID,
  page_id: this.data.pageID,
  results_per_source: getSearchSources(),
  refinement_occurred: false,
};
var payloadObject = {
  action: "TestAction",
  payload: payload,
};
c.server.get(payloadObject);

//server script
if (input && input.action === "TestAction") {
  input.action = "";
  var textSearchAnalytics = new GlideSPSearchAnalytics().publish(JSON.stringify(input.payload));
  return;
}
```

This example collects direct search-results-clicked data from a custom search widget and passes it to the search analytics [sys_search_result_clicked] table.

```javascript
function setUserLocationCoords(cb) {
  var onSuccess = function(pos) {
    return cb({
      latitude: pos.coords.latitude,
      longitude: pos.coords.longitude,
    });
  };
}
```
var onError = function() {
    return cb({
        latitude: null,
        longitude: null,
    });
};
return window.navigator.geolocation.getCurrentPosition(onSuccess, onError, {
    enableHighAccuracy: true,
});

function trackSearchResultClicked(resultClicked, rank) {
    if (!rank || rank < 1) return;
    var c = $scope;
    var query = _.get(c.data, "q");
    var results = _.get(c.data, "results", []);
    var result = results.find(function(e) {
        return e.primary.trim() === resultClicked.trim();
    });
    var description = result.name != null ? result.name : result.primary;
    var sourceTable = result.table != null ? result.table : null;
    var payloadObject = {
        action: "TestAction",
        payload: {
            query: query,
            portal_id: c.portal.sys_id,
            page_id: $scope.page && $scope.page.id,
            results_per_source: getSearchSources(c),
            refinement_occurred: false,
            click_rank: rank,
            browser_info: $window.navigator.userAgent,
            location: {},
            result_clicked_sys_id: result.sys_id,
            label_description: description,
            source_table: sourceTable,
        },
    };
    setUserLocationCoords(function(coords) {
        payloadObject.payload.location.latitude = coords.latitude;
        payloadObject.payload.location.longitude = coords.longitude;
        $window.spSearchAnalytics = {
            query: query,
            refinement_occurred: false,
        };
    });
c.server.get(payloadObject);
});
}
// Event delegation for Updating click rank
$(".panel").on("click", ".result-item a", function(e) {
var index = $(e.currentTarget).parent().parent().data("index");
var resultClicked = e.currentTarget.innerText;
trackSearchResultClicked(resultClicked, index + 1);
});
// server script
if (input && input.action === "TestAction") {
input.action = "";
var textSearchAnalytics = new
GlideSPSearchAnalytics().publish(JSON.stringify(input.payload));
return;
}

GlideStringUtil - Scoped, Global
Provides string handling methods.
Access these methods using the static object GlideStringUtil. This class is
available in scoped and global scripts.
GlideStringUtil - dotToUnderBar(String sourceString)
Replaces periods with underscore characters.
Parameters
Name

Type

Description

sourceString

String

Text to process.

Returns
Type

Description

String

Text with periods replaced with underscores.

var filename="../../../../../../etc/passwd";
cleanFilename=GlideStringUtil.dotToUnderBar(filename);
gs.info(cleanFilename);

Output:

```
__/__/__/__/__/__/etc/passwd
```

**GlideStringUtil - escapeAllQuotes(String sourceString)**
Removes quotes from a string.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceString</td>
<td>String</td>
<td>The string to be processed.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The string with quotes removed.</td>
</tr>
</tbody>
</table>

```java
mystring="let's escape some quotes";
escapeQuote=GlideStringUtil.escapeAllQuotes(mystring);
gs.info(escapeQuote);
```

Output:

```
lets escape some quotes
```

**GlideStringUtil - escapeForHomePage(String sourceString)**
Replaces problem characters with escape characters.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceString</td>
<td>String</td>
<td>Text to process.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Text with problem characters replaced with escape characters.</td>
</tr>
</tbody>
</table>
mystring="<test> string \n to escape";
escapedString=GlideStringUtil.escapeForHomePage(mystring);
gs.info(escapedString);

Output:
%3ctest%3e string \n to escape

**GlideStringUtil - escapeHTML(String htmlString)**
Replaces illegal characters with their escape codes.

Using this method removes illegal characters that might cause the UI to render improperly, or trigger a client side attack such as JavaScript or HTML injection.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>htmlString</td>
<td>String</td>
<td>Text to process.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Text with illegal characters replaced with their escape codes.</td>
</tr>
</tbody>
</table>

mydata='"<>\';
mydata=GlideStringUtil.escapeHTML(mydata);
gs.info(mydata);

Output:
"&quot;&amp;&lt;&gt;"

**GlideStringUtil - escapeNonPrintable(String sourceString)**
Replaces non-printable characters with their printable notation.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceString</td>
<td>String</td>
<td>Text to process.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>String</td>
<td>Text with non-printable characters replaced with printable notation.</td>
<td></td>
</tr>
</tbody>
</table>

```java
mystring="test \x09 non \x00 printable \x07 chars";
escapedString=GlideStringUtil.escapeNonPrintable(mystring);
gs.info(escapedString);
```

**Output:**

test 	 non   printable  chars

### GlideStringUtil - escapeQueryTermSeparator(String sourceString)
Replaces query term separators “^” with their escape sequence “^^”.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceString</td>
<td>String</td>
<td>Text to process.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Text with query term separators replaced with the escape characters.</td>
</tr>
</tbody>
</table>

```java
myquery="test^Test";
escapedQuery=GlideStringUtil.escapeQueryTermSeparator(myquery);
gs.info(escapedQuery);
```

**Output:**

test^^Test

### GlideStringUtil - escapeTicks(String sourceString)
Replaces quotes with escape characters by adding a backslash before each quote.
### GlideStringUtil - `getHTMLValue(String sourceString)`

**Description**

Replaces illegal HTML characters into HTML notation.

Using this method removes illegal characters that might cause the UI to render improperly, or trigger a client side attack such as JavaScript or HTML injection.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceString</td>
<td>String</td>
<td>Text to process.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Text with illegal characters replaced with HTML notation.</td>
</tr>
</tbody>
</table>

```java
define (string) mydata='&';
glideStringUtil.getHTMLValue(mydata);
gs.info(htmlvalue);
```

**Output:**

```
&amp;
```

**GlideStringUtil - getNumeric(String sourceString)**

Extracts numeric characters from a string.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceString</td>
<td>String</td>
<td>Text to process.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Text containing only numeric characters.</td>
</tr>
</tbody>
</table>

```java
mystring='123 test 456 String 789 cleaning';
onlyNumeric=GlideStringUtil.getNumeric(mystring);
gs.info(onlyNumeric);
```

**Output:**

```
123456789
```

**GlideStringUtil - isBase64(String sourceString)**

Validates whether the specified string is a valid base64 string.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceString</td>
<td>String</td>
<td>Text to process.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates whether the specified string is in valid base64 format. Possible values:  
  - true: Valid base64 formatted string.  
  - false: Invalid base64 formatted string. |
// (adding a *** to corrupt the base64 format)
base64="GethdTYehtsetB***";
isValid=GlideStringUtil.isBase64(base64);
gs.info(isValid);

Output:
false

GlideStringUtil - isEligibleSysID(String sourceString)
Validates whether the specified string is in valid sys_id format.

The sys_id format is a sequence of 32 hexadecimal characters where all the characters are in the range [0-9, a-f, A-F].

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceString</td>
<td>String</td>
<td>Text to process.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the specified string is in valid sys_id format. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Valid sys_id formatted string.</td>
</tr>
<tr>
<td></td>
<td>• false: Invalid sys_id formatted string.</td>
</tr>
</tbody>
</table>

sysID="62826bf03710200044e0bfc8bcbe5df1";
isElig=GlideStringUtil.isEligibleSysID(sysID);
gs.info(isElig);

Output:
true

GlideStringUtil - newLinesToBreaks(String sourceString)
Replaces the new line character, /n, with a break code, <br/>.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceString</td>
<td>String</td>
<td>Text to process.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Text with new line characters replaced with HTML break code.</td>
</tr>
</tbody>
</table>

mystring="new line break \n, this is after the break";
replaceNewLine=GlideStringUtil.newLinesToBreaks(mystring);
gs.info(replaceNewLine);

Output:
new line break <br/>, this is after the break

GlideStringUtil - normalizeWhitespace(String sourceString)
Replaces carriage returns, line feeds, and tabs with spaces, and then removes leading, trailing, and duplicate spaces.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceString</td>
<td>String</td>
<td>Text to process.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Text with carriage returns, line feeds, and tabs replaced with spaces, and then leading, trailing, and duplicate spaces removed.</td>
</tr>
</tbody>
</table>

mystring="test with \n (new line) and \t (tabulation)";
normalizedString=GlideStringUtil.normalizeWhitespace(mystring);
gs.info(normalizedString);

Output:
test with (new line) and (tabulation)
GlideStringUtil - unEscapeHTML(String htmlString)

Replaces escape characters with their respective character.

This method replaces these escape characters: &lt; &gt; &nbsp; &amp; &quot;.

⚠️ Note: In scoped applications call this method as unescapeHTML(String). In global applications call this method as unEscapeHTML(String).

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>htmlString</td>
<td>String</td>
<td>String to process.</td>
</tr>
</tbody>
</table>

This code example shows the method being called in a global application.

```java
mydata="&quot;&lt;&gt;&amp;';
unescaped=GlideStringUtil.unEscapeHTML(mydata);
gs.info(unescaped);
```

Output:

"<>"&

This code example shows the method being called in a scoped application.

```java
mydata="&quot;&lt;&gt;&amp;';
unescaped=GlideStringUtil.unescapeHTML(mydata);
gs.info(unescaped);
```

Output:

"<>"&

GlideSysAttachment - Scoped

The GlideSysAttachment API provides a way to handle attachments. Content is returned as a string, not as a byte array when `getcontent()` is called.
Content is returned as a GlideScriptableInputStream object when `getContentStream()` is called. The GlideScriptableInputStream contains the actual bytes not converted into a String.

**Scoped GlideSysAttachment - copy(String sourceTable, String sourceID, String targetTable, String targetID)**

Copies attachments from the source record to the target record.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceTable</td>
<td>String</td>
<td>Name of the table with the attachments to be copied.</td>
</tr>
<tr>
<td>sourceID</td>
<td>String</td>
<td>Source table's sys_id.</td>
</tr>
<tr>
<td>targetTable</td>
<td>String</td>
<td>Name of the table on which to add the attachments.</td>
</tr>
<tr>
<td>targetID</td>
<td>String</td>
<td>Target table's sys_id.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Array of sys_ids of the attachments that were copied.</td>
</tr>
</tbody>
</table>

```glide
var attachment = new GlideSysAttachment();
var incidentSysID = 'ab1b30031b04ec101363ff37dc4bcfc';
var incGR = new GlideRecord('incident');
incGR.get(incidentSysID);
var copiedAttachments = attachment.copy('incident', incidentSysID, 'problem',
    incGR.getValue('problem_id'));
gs.info('Copied attachments: ' + copiedAttachments);
```

**Output**

```
Copied attachments: 6e4621df1bc420501363ff37dc4bcba2,a87769531b0820501363ff37dc4bcba2
```

**Scoped GlideSysAttachment - deleteAttachment(String attachmentID)**

Deletes the specified attachment.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attachmentID</td>
<td>String</td>
<td>Attachment's sys_id.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var attachment = new GlideSysAttachment();
var attachmentSysID = 'a87769531b0820501363ff37dc4bcba2';
attachment.deleteAttachment(attachmentSysID);
```

**Scoped GlideSysAttachment - getAttachments(String tableName, String sys_id)**

Returns a GlideRecord containing the matching attachment metadata such as name, type, or size.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table to which the attachment belongs; for example, incident.</td>
</tr>
<tr>
<td>sys_id</td>
<td>String</td>
<td>The sys_id of record to which the attachment belongs.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>GlideRecord object containing the matching attachment metadata such as name, type, or size.</td>
</tr>
</tbody>
</table>

The following script lists attachment file names for a record with two attachments.

```javascript
var attachment = new GlideSysAttachment();

var agr = attachment.getAttachments('<table_name>', '<record_sys_id>');
```
while(agr.next())
gs.info(agr.getValue('file_name'));

Output:

*** Script: filename1.txt
*** Script: filename2.txt

Scoped GlideSysAttachment - getContent(GlideRecord sysAttachment)
Returns the attachment content as a string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysAttachment</td>
<td>GlideRecord</td>
<td>Attachment record.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Attachment contents as a string. Returns up to 5MB of data.</td>
</tr>
</tbody>
</table>

var attachment = new GlideSysAttachment();
var incidentSysID = 'ab1b30031b04ec101363ff37dc4bcfbc';

var agr = attachment.getAttachments('incident', incidentSysID);

if (agr.next()) {
    var attachmentContent = attachment.getContent(agr);
    gs.info('Attachment content: ' + attachmentContent);
}

Output

Attachment content: I am text in a txt file attached to a record.

Scoped GlideSysAttachment - getContentBase64(GlideRecord sysAttachment)
Returns the attachment content as a string with base64 encoding.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysAttachment</td>
<td>GlideRecord</td>
<td>Attachment record.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Attachment contents as a string with base64 encoding. Returns up to 5MB of data.</td>
</tr>
</tbody>
</table>

```javascript
var attachment = new GlideSysAttachment();
var incidentSysID = 'ab1b30031b04ec101363ff37dc4bcbfc';

var agr = attachment.getAttachments('incident', incidentSysID);

if (agr.next()) {
    var attachmentContent = attachment.getContentBase64(agr);
    gs.info('Attachment content base64 encoded: ' + attachmentContent);
}
```

Output

```
Attachment content base64 encoded: SSBhbSB0ZXh0Lg==
```

**Scoped GlideSysAttachment - getContentStream(String sysID)**

Returns a GlideScriptableInputStream object given the sys_id of an attachment.

You can use the GlideTextReader API to read the content stream.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysID</td>
<td>String</td>
<td>Attachment sys_id.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideScriptableInputStream</td>
<td>Stream that contains the attachment content.</td>
</tr>
</tbody>
</table>
```
var attachment = new GlideSysAttachment();
var attachmentSysID = '6e4621df1bc420501363ff37dc4bcb0';
var attachmentContentStream = attachment.getContentStream(attachmentSysID);
gs.info('Attachment content stream: ' + attachmentContentStream);
```

**Output**
```
Attachment content stream: com.glide.communications.GlideScriptableInputStream@14bd299
```

**Scoped GlideSysAttachment - GlideSysAttachment()**

Creates an instance of the GlideSysAttachment class.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Scoped GlideSysAttachment - write(GlideRecord record, String fileName, String contentType, String content)**

Attaches a specified attachment to the specified record.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>GlideRecord</td>
<td>Record to which to attach the attachment.</td>
</tr>
<tr>
<td>fileName</td>
<td>String</td>
<td>Attachment file name.</td>
</tr>
<tr>
<td>contentType</td>
<td>String</td>
<td>Attachment content type.</td>
</tr>
<tr>
<td>content</td>
<td>String</td>
<td>Attachment content.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Attachment sys_id. Returns null if the attachment was not added.</td>
</tr>
</tbody>
</table>
rec.get('78271e1347c12200e0ef563dbb9a7109');
var fileName = 'example.txt';
var contentType = 'text/csv';
var content = 'The text that is stored inside my file';

var agr = attachment.write(rec, fileName, contentType, content);
gs.info('The attachment sys_id is: ' + agr);

Output:
The attachment sys_id is: 01271e4317c13311e0ef563dbb9abe34

Scoped GlideSysAttachment - writeBase64(GlideRecord now_GR, String fileName, String contentType, String content_base64Encoded)
Inserts an attachment for the specified record using base64 encoded content.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>Record to which the attachment is to be attached.</td>
</tr>
<tr>
<td>fileName</td>
<td>String</td>
<td>Attachment's file name.</td>
</tr>
<tr>
<td>contentType</td>
<td>String</td>
<td>Attachment's content type.</td>
</tr>
<tr>
<td>content</td>
<td>String</td>
<td>Attachment content in base64 format.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the attachment created.</td>
</tr>
</tbody>
</table>

var attachment = new GlideSysAttachment();

var rec = new GlideRecord('incident');
var incidentSysID = 'ab1b30031b04ec101363ff37dc4bcfbc';
rec.get(incidentSysID);
var fileName = 'example.txt';
var contentType = 'text/csv';
var base64Encodedcontent = 'SSBhbSB0ZXh0Lg==';
var agr = attachment.writeBase64(rec, fileName, contentType, base64Encodedcontent);

gs.info('The attachment sys_id is: ' + agr);

Output

The attachment sys_id is: 10cde9971b0820501363ff37dc4bcba6

**Scoped GlideSysAttachment - writeContentStream(GlideRecord now_GR, String fileName, String contentType, GlideScriptableInputStream inputStream)**

Inserts an attachment using the input stream.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>now_GR</td>
<td>GlideRecord</td>
<td>Record to which the attachment is to be attached.</td>
</tr>
<tr>
<td>fileName</td>
<td>String</td>
<td>Attachment's file name.</td>
</tr>
<tr>
<td>contentType</td>
<td>String</td>
<td>Attachment's content type.</td>
</tr>
<tr>
<td>content</td>
<td>GlideScriptableInputStream</td>
<td>Attachment content.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the attachment created.</td>
</tr>
</tbody>
</table>

Attaches a content stream from the sys_attachment table to a test_table record.

```javascript
function copyAttachmentToGlideRecord(conceptSysId) {

  // Get record from test_table using sys_id
  var targetGlideRecord = new GlideRecord("test_table");
  if (!targetGlideRecord.get(conceptSysId)) {
    throw ("Cannot find record created by test with sys_id: " + conceptSysId);
  }

  // Get record from sys_attachment table
  var sourceAttachmentGlideRecord = new GlideRecord('sys_attachment');
  sourceAttachmentGlideRecord.query();
  sourceAttachmentGlideRecord.next();
}
```
// Get field values from retrieved sys_attachment record
var fileName = sourceAttachmentGlideRecord.getValue('file_name');
var contentType = sourceAttachmentGlideRecord.getValue('content_type');
var sourceAttachmentSysId = sourceAttachmentGlideRecord.getValue('sys_id');

// Attach sys_attachment record content stream to test_table record
var gsa = new GlideSysAttachment();
gsa.writeContentStream(
    targetGlideRecord,
    fileName,
    contentType,
    gsa.getContentStream(sourceAttachmentSysId));
gs.info("Attachment created");
}

**GlideSysListControl - Scoped**

The scoped GlideSysListControl class allows you to determine if the New or Edit buttons are displayed.

**GlideSysListControl - getControlID()**

Returns the sys_id for the control.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

```javascript
var sysListCtrl = new GlideSysListControl("incident");
var controlID = sysListCtrl.getControlID();
gs.info(controlID);
```

Output:

```
91a807a60a0a3c74012113e28b47ca2e
```
**GlideSysListControl - GlideSysListControl(String tableName)**

Instantiates a GlideSysListControl object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table</td>
</tr>
</tbody>
</table>

**GlideSysListControl - isOmitEditButton()**

Returns true if the edit button is not displayed.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True when the edit button is not displayed.</td>
</tr>
</tbody>
</table>

```javascript
var sysListCtrl = new GlideSysListControl("incident");
var isOmitted = sysListCtrl.isOmitEditButton();
gs.info(isOmitted);
```

Output:

false

**GlideSysListControl - isOmitNewButton()**

Returns true when the New button is not displayed.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## GlideSystem - Global

The GlideSystem API, which is referred to by the variable name `gs` in any server-side JavaScript, provides a number of convenient methods to get information about the system, the current logged in user, and date/time information.

Many of the GlideSystem methods facilitate the easy inclusion of dates in query ranges, and are most often used in filters and reporting.

### GlideSystem - addErrorMessage(Object message)

Adds an error message for the current session.

Use `getErrorMessages()` to retrieve a list of error messages currently being shown.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>Object</td>
<td>The message to add.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var sysListCtrl = new GlideSysListControl("incident");
var isOmitted = sysListCtrl.isOmitNewButton();
gs.info(isOmitted);
```

Output:

false
var user_password = request.getParameter("user_password");
var min_len = 8;
var rules = "Password must be at least " + min_len + 
  " characters long and contain a digit, an uppercase letter, and a lowercase letter.";
if (user_password.length() < min_len) {
  gs.addErrorMessage("TOO SHORT: " + rules);
  return false;
}
var digit_pattern = new RegExp("[0-9]", "g");
if (!digit_pattern.test(user_password)) {
  gs.addErrorMessage("DIGIT MISSING: " + rules);
  return false;
}
var upper_pattern = new RegExp("[A-Z]", "g");
if (!upper_pattern.test(user_password)) {
  gs.addErrorMessage("UPPERCASE MISSING: " + rules);
  return false;
}
var lower_pattern = new RegExp("[a-z]", "g");
if (!lower_pattern.test(user_password)) {
  gs.addErrorMessage("LOWERCASE MISSING: " + rules);
  return false;
}
return true; // password is OK
}  

Scoped equivalent

To use the addErrorMessage() method in a scoped application, use the corresponding scoped method: Scoped GlideSystem - addErrorMessage(String message).

GlideSystem - addInfoMessage(Object message)

Adds an info message for the current session.

Use getInfoMessages() to retrieve the list of info messages being shown. This method is not supported for asynchronous business rules and cannot be used within transform scripts.
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>Object</td>
<td>The message to add.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
if ((!current.u_date1.nil()) && (!current.u_date2.nil())) {
    var start = current.u_date1.getGlideObject().getNumericValue();
    var end = current.u_date2.getGlideObject().getNumericValue();
    if (start > end) {
        gs.addInfoMessage('start must be before end');
        current.u_date1.setError('start must be before end');
        current.setAbortAction(true);
    }
}
```

**Scoped equivalent**

To use the `addInfoMessage()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - addInfoMessage(String message)**.

**GlideSystem - addMessage(String type, Object message)**

Adds a message for the current session.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>Type of message, such as error or info.</td>
</tr>
<tr>
<td>message</td>
<td>Object</td>
<td>Message to add to the current session.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

GlideSystem - beginningOfLastMonth()

Gets the date and time for the beginning of last month in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of last month, in the format yyyy-mm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>

This example sets the date and time of the GlideDateTime object to the beginning of last month.

```javascript
var date = new GlideDate();
date.setValue(gs.beginningOfLastMonth());
var dateasint = date.toString().replace('-','');
gs.print(dateasint);
```

Scoped equivalent

To use the `beginningOfLastMonth()` method in a scoped application, use the corresponding scoped method: Scoped GlideSystem - beginningOfLastMonth().

GlideSystem - beginningOfLastWeek()

Returns the date and time for the beginning of last week in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of last week.</td>
</tr>
</tbody>
</table>
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example sets the value of the current Glide date/time record to the beginning of last week.

```javascript
var gdt2 = new GlideDateTime(dt);
gdt2.setValue(gs.beginningOfLastWeek());
```

Scoped equivalent

To use the `beginningOfLastWeek()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - beginningOfLastWeek()`.

**GlideSystem - beginningOfNextWeek()**

Returns the date and time for the beginning of next week in GMT.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of next week.</td>
</tr>
<tr>
<td></td>
<td>Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example sets the value of the current Glide date/time record to the beginning of next week.

```javascript
var gdt2 = new GlideDateTime(dt);
gdt2.setValue(gs.beginningOfNextWeek());
```

Scoped equivalent

To use the `beginningOfNextWeek()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - beginningOfNextWeek()`.
GlideSystem - beginningOfNextMonth()

Returns the date and time for the beginning of next month in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of next month.</td>
</tr>
<tr>
<td></td>
<td>Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example sets the value of the current Glide date/time record to the beginning of next month.

```javascript
var gdt2 = new GlideDateTime(dt);
gdt2.setValue(gs.beginningOfNextMonth());
```

Scoped equivalent

To use the `beginningOfNextMonth()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - beginningOfNextMonth()`.

GlideSystem - beginningOfNextYear()

Returns the date and time for the beginning of next year in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The GMT beginning of next year, in the format yyyy-mm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>
This example sets the value of the current Glide date/time record to the beginning of next year.

```java
var gdt2 = new GlideDateTime(dt);
gdt2.setValue(gs.beginningOfNextYear());
```

**Scoped equivalent**

To use the `beginningOfNextYear()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - beginningOfNextYear()`.

### GlideSystem - beginningOfThisMonth()

Returns the date and time for the beginning of the current month in GMT.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of the current month.</td>
</tr>
<tr>
<td></td>
<td>Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example sets the value of the current Glide date/time record to the beginning of this month.

```java
var gdt2 = new GlideDateTime(dt);
gdt2.setValue(gs.beginningOfThisMonth());
```

**Scoped equivalent**

To use the `beginningOfThisMonth()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - beginningOfThisMonth()`.

### GlideSystem - beginningOfThisQuarter()

Returns the date and time for the beginning of the current quarter in GMT.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of the current quarter.</td>
</tr>
<tr>
<td></td>
<td>Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example sets the value of the current Glide date/time record to the beginning of the current quarter.

```javascript
var gdt2 = new GlideDateTime(dt);
gdt2.setValue(gs.beginningOfThisQuarter());
```

Scoped equivalent

To use the `beginningOfThisQuarter()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - beginningOfThisQuarter()`.

**GlideSystem - beginningOfThisWeek()**

Returns the date and time for the beginning of this week in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of the current week.</td>
</tr>
<tr>
<td></td>
<td>Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example sets the value of the current Glide date/time record to the beginning of the current week.
var gdt2 = new GlideDateTime(dt);
gdt2.setValue(gs.beginningOfThisWeek());

**Scoped equivalent**

To use the `beginningOfThisWeek()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - beginningOfThisWeek()`.

**GlideSystem - beginningOfThisYear()**

Returns the date and time for the beginning of this year in GMT.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of the current year. Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example sets the value of the current Glide date/time record to the beginning of the current year.

```javascript
var gdt2 = new GlideDateTime(dt);
gdt2.setValue(gs.beginningOfThisYear());
```

**Scoped equivalent**

To use the `beginningOfThisYear()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - beginningOfThisYear()`.

**GlideSystem - beginningOfToday()**

Retrieves the date and time for the beginning of today in GMT.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of the current day.</td>
</tr>
<tr>
<td></td>
<td>Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example sets the value of the current Glide date/time record to the beginning of the current day.

```javascript
var gdt2 = new GlideDateTime(dt);
gdt2.setValue(gs.beginningOfToday());
```

GlideSystem - beginningOfTomorrow()

Retrieves the (UTC) beginning of tomorrow adjusted for the timezone of the current session.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of tomorrow.</td>
</tr>
<tr>
<td></td>
<td>Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

```javascript
var today = new GlideDateTime(gs.beginningOfTomorrow()).getNumericValue();
```

GlideSystem - beginningOfYesterday()

Retrieves the date and time for the beginning of yesterday in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The GMT beginning of yesterday, in the format yyyy-mm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>

```javascript
var start = new GlideDateTime();
start.setValue(gs.beginningOfYesterday());
```

**GlideSystem - calDateDiff(String startDate, String endDate, Boolean numericValue)**

Calculate the difference between two dates using the default calendar.

Calendars are now legacy. If Schedules are being used, see the topic Calculate Duration Given a Schedule.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startDate</td>
<td>String</td>
<td>Starting date to compare in the current user’s date format.</td>
</tr>
<tr>
<td>endDate</td>
<td>String</td>
<td>Ending date to compare in the current user’s date format.</td>
</tr>
<tr>
<td>numericValue</td>
<td>Boolean</td>
<td>Flag that indicates the format of the returned time value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Return value is formatted in number of seconds</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Return value is formatted ddd hh:mm:ss.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>If the numericValue parameter is true, returns the difference between the two dates as an integer number of seconds. If false, returns the difference between the two dates in the format ddd hh:mm:ss.</td>
</tr>
</tbody>
</table>
```
var endDateTime = gs.nowDateTime();
gs.print('--- Total records: ' + countRecordsTotal);
gs.print('--- End time: ' + endDateTime);
gs.print('Time diff: ' + gs.calDateDiff(startDateTime, endDateTime));
```

### GlideSystem - dateDiff(String startDate, String endDate, Boolean numericValue)

Calculates the difference between two dates.

This method expects the earlier date as the first parameter and the later date as the second parameter; otherwise, the method returns the difference as a negative value. Use `getDisplayValue()` to convert the strings to the expected format.

This method expects parameters in the user/system date time format, which may not be the same as the internal format. Using parameters in formats other than the user/system date time format may return invalid results.

If you are working with GlideDateTime objects use the GlideDateTime `subtract()` method instead of `dateDiff()`.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startDate</td>
<td>String</td>
<td>The starting date to compare in the current user's date format.</td>
</tr>
<tr>
<td>endDate</td>
<td>String</td>
<td>The ending date to compare in the current user's date format.</td>
</tr>
<tr>
<td>numericValue</td>
<td>Boolean</td>
<td>If true, the return value will be formatted in number of seconds; if false, returns the difference between the two dates in the format ddd hh:mm:ss.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>If the numericValue parameter is true, returns the difference between the two dates as an integer number of seconds; if false, returns the difference between the two dates in the format ddd hh:mm:ss.</td>
</tr>
</tbody>
</table>

```java
// Given two date/times as DateTime objects
// Set the values this way to ensure a consistent input time
var datel = new GlideDateTime();
```
var date2 = new GlideDateTime();
date1.setDisplayValueInternal('2014-01-01 12:00:00');
date2.setDisplayValueInternal('2014-01-01 13:00:00');

// Determine the difference as number of seconds (returns a string)
// Use getDisplayValue() to convert the string to the format expected by dateDiff()
var diffSeconds = gs.dateDiff(date1.getDisplayValue(), date2.getDisplayValue(), true);

// JavaScript will coerce diffSeconds from a string to a number
// since diffSeconds is being compared to a number
var msg = (diffSeconds <= 0) ? ' is on or after ' : ' is before ';
gs.print(date1.getDisplayValue() + msg + date2.getDisplayValue());

GlideSystem - dateGenerate(String date, String range)
Generates a date and time for the specified date in GMT.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>String</td>
<td>Date to generate in GMT. Format: yyyy-mm-dd</td>
</tr>
<tr>
<td>range</td>
<td>String</td>
<td>Start, end, or a time. Format: 24-hour hh:mm:ss</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Date and time in the format yyyy-mm-dd hh:mm:ss. If range is start, the return value is yyyy-mm-dd 00:00:00. If range is end, the return value is yyyy-mm-dd 23:59:59.</td>
</tr>
</tbody>
</table>

This example shows using dateGenerate() to set the start date when querying records in the Incident table.

var tableData = new GlideRecord('incident');
tableData.addEncodedQuery("sys_created_onBETWEENjavascript:gs.dateGenerate('2015-10-07','00:00:00')@javascript:gs.daysAgoEnd(0)^priority=1^severityIN1,2");
tableData.query();
gs.addInfoMessage("Count: " +tableData.getRowCount());
Scoped equivalent

To use the `dateGenerate()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - dateGenerate(String date, String range).**

**GlideSystem - daysAgo(Number days)**

Returns a date and time for a certain number of days ago.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>Number</td>
<td>Number of days</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT of the specified number of days ago. Format: yyyy-mm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>

```javascript
function contractNoticeDue() {
    var now_GR = new GlideRecord("contract");
    now_GR.addQuery("u_contract_status", "Active");
    now_GR.query();
    while (now_GR.next()) {
        if ((now_GR.u_termination_date <= gs.daysAgo(-90)) && (now_GR.u_contract_duration == "Long")) {
            now_GR.u_contract_status = "In review";
        } else if ((now_GR.u_termination_date <= gs.daysAgo(-50)) && (now_GR.u_contract_duration == "Medium")) {
            now_GR.u_contract_status = "In review";
        } else if ((now_GR.u_termination_date <= gs.daysAgo(-10)) && (now_GR.u_contract_duration == "Short")) {
            now_GR.u_contract_status = "In review";
        }
    }
    now_GR.update();
}
```
Scoped equivalent
To use the `daysAgo()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - daysAgo(Number days)`.

GlideSystem - `daysAgoEnd(Number days)`
Returns a date and time for the end of the day a specified number of days ago.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>days</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

This example shows using `daysAgoEnd()` to set the end date when querying records in the Incident table.

```javascript
var tableData = new GlideRecord('incident');
tableData.addEncodedQuery("sys_created_on BETWEEN javascript:gs.dateGenerate('2015-10-07','00:00:00')@javascript:gs.daysAgoEnd(0)" +"priority=1" +"severity IN 1,2");
tableData.query();
gs.addInfoMessage("Count: " +tableData.getRowCount());
```

Scoped equivalent
To use the `daysAgoEnd()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - daysAgoEnd(Number days)`.

GlideSystem - `daysAgoLocal(Number days)`
Returns the date and time of the beginning of the day for the specified number of days ago. The returned date and time reflect the time zone of the current session (local time).

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>days</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Local date and time for the beginning of the day in the user-defined date time format. If the date time format is not modified from its initial value the format is yyyymm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>

```java
if (due_in == "1 Day") {
    dd = gs.daysAgoLocal(-1);
}
if (due_in == "1 Week") {
    dd = gs.daysAgoLocal(-7);
}
```

GlideSystem - daysAgoStart(Number days)

Returns a date and time for the beginning of the day a specified number of days ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>String</td>
<td>Integer number of days</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT start of the day in the format yyyymm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

```java
var now_GR = new GlideRecord('sysapproval_approver');
now_GR.addQuery('state', 'requested');
now_GR.addQuery('sys_updated_on', '<', gs.daysAgoStart(5));
now_GR.query();
```

Scoped equivalent

To use the daysAgoStart() method in a scoped application, use the corresponding scoped method: Scoped GlideSystem - daysAgoStart(Number days).
GlideSystem - endOfLastMonth()

Returns the date and time for the end of last month in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT of the end of last month. Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example shows how to query a report record from the last day of last month.

```javascript
var month = gs.endOfLastMonth();
var monthd = new GlideDateTime(month);
monthd.addDays(-1);

var queueLast = new GlideRecord('u_amazon_connect_phone_metrics');
queueMtd.addQuery('u_queue_name',queueNames[i]);
queueMtd.addEncodedQuery('u_time_range=MTD');
queueMtd.addEncodedQuery('u_report_date'+ monthd);
queueMtd.orderByDesc('u_report_date');
queueMtd.query();

if(queueMtd.next()){
    gs.info(queueMtd.u_report_date);
}
```

Scoped equivalent

To use the `endOfLastMonth()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - endOfLastMonth()**.

GlideSystem - endOfLastWeek()

Returns the date and time for the end of last week in GMT.
This example shows how to query records opened on the last week of the previous month.

```javascript
var inc = new GlideRecord('incident');
inc.addQuery('active=true^priority=1^opened_atONLast
month@javascript:gs.beginningOfLastMonth()@javascript:gs.endOfLastMonth()^opened_atONLast
week@javascript:gs.beginningOfLastWeek()@javascript:gs.endOfLastWeek()');
inc.query();
while(inc.next())
{
    gs.addInfoMessage(inc.getRowCount());
}
```

**Scoped equivalent**

To use the `endOfLastWeek()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - endOfLastWeek()**.

**GlideSystem - endOfLastYear()**

Returns the date and time for the end of last year in GMT.
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in format yyyy-mm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>

This example shows how to query records created for all records created in the last year.

```javascript
var inc = new GlideRecord('incident');
inc.addEncodedQuery('sys_created_onONLast
    year@javascript:gs.beginningOfLastYear()@javascript:gs.endOfLastYear()');
inc.query();
while(inc.next()){
    inc.assignment_group = "d625dccec0a8016700a222a0f7900d06";
    inc.update();
}
```

Scoped equivalent

To use the `endOfLastYear()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - endOfLastYear()**.

**GlideSystem - endOfNextMonth()**

Returns the date and time for the end of next month in GMT.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT data and time.</td>
</tr>
<tr>
<td></td>
<td>Format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example shows how to query KB knowledge records created since the beginning of today until the end of next month.

```javascript
var query = "kb_knowledge_base=e81c9a0ddbc15810c38f0763b99619c1^ORkb_knowledge_base=21302e89db055810c3"
```
Scoped equivalent

To use the `endOfNextMonth()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - endOfNextMonth()**.

**GlideSystem - endOfNextWeek()**

Returns the date and time for the end of next week in GMT.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

This example shows how to use `endOfNextWeek()` in a query to obtain all visitors in the past week.
var title = 'Visitors arriving this Week';
var visitorQuery = 'active=true^category=visitor_request^u_my_start_dateONThis
week@javascript:gs.beginningOfThisWeek()@javascript:gs.endOfNextWeek()';

Scoped equivalent
To use the endOfNextWeek() method in a scoped application, use the corresponding scoped method: Scoped GlideSystem - endOfNextWeek().

GlideSystem - endOfNextYear()
Returns the date and time for the end of next year in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT date and time for the end of next year.</td>
</tr>
<tr>
<td></td>
<td>Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example shows how to use endOfNextYear() to set the GlideDateTime object to the end of next year.

```javascript
setEndDate : function(dt) {
    var gdt2 = new GlideDateTime(dt);
    gdt2.setValue(gs.endOfNextYear());
}
```

Scoped equivalent
To use the endOfNextYear() method in a scoped application, use the corresponding scoped method: Scoped GlideSystem - endOfNextYear().

GlideSystem - endOfThisMonth()
Returns the date and time for the end of this month in GMT.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| String  | GMT date and time for the end of this month.  
|         | Format yyyy-mm-dd hh:mm:ss                                   |

This example shows how to use `endOfThisMonth()` to set the GlideDateTime object to the end of the current month.

```javascript
setEndDate : function(dt) {
    var gdt2 = new GlideDateTime(dt);
    gdt2.setValue(gs.endOfThisMonth());
}
```

Scoped equivalent

To use the `endOfThisMonth()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - endOfThisMonth()`.

GlideSystem - endOfThisQuarter()

Returns the date and time for the end of this quarter in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| String  | GMT date and time for the end of this quarter.  
|         | Format: yyyy-mm-dd hh:mm:ss                                   |

This example shows how to use `endOfThisQuarter()` to set the GlideDateTime object to the end of the current month.
setEndDate : function(dt) {
    var gdt2 = new GlideDateTime(dt);
    gdt2.setValue(gs.endOfThisQuarter());
}

Scoped equivalent

To use the endOfThisQuarter() method in a scoped application, use the corresponding scoped method: Scoped GlideSystem - endOfThisQuarter().

GlideSystem - endOfThisWeek()

Returns the date and time for the end of this week in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT date and time for the end of this week. Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example shows how to use endOfThisWeek() to set the GlideDateTime object to the end of the current month.

setEndDate : function(dt) {
    var gdt2 = new GlideDateTime(dt);
    gdt2.setValue(gs.endOfThisWeek());
}

Scoped equivalent

To use the endOfThisWeek() method in a scoped application, use the corresponding scoped method: Scoped GlideSystem - endOfThisWeek().

GlideSystem - endOfThisYear()

Returns the date and time for the end of this year in GMT.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT date and time for the end of this year. Format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

This example shows how to use `endOfThisYear()` to set the GlideDateTime object to the end of the current month.

```javascript
setEndDate : function(dt) {
    var gdt2 = new GlideDateTime(dt);
    gdt2.setValue(gs.endOfThisYear());
}
```

### Scoped equivalent

To use the `endOfThisYear()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - endOfThisYear()**.

### GlideSystem - endOfToday()

Retrieves the date and time for the end of today in GMT.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>

```javascript
var beginToday = gs.beginningOfToday();
var endToday = gs.endOfToday();
var beginTomorrow = gs.beginningOfTomorrow();
```
```javascript
var endTomorrow = gs.endOfTomorrow();
var beginYesterday = gs.beginningOfYesterday();
var endYesterday = gs.endOfYesterday();

gs.info('beginningOfToday: ' + beginToday);
gs.info('endOfToday: ' + endToday);
gs.info('----------');
gs.info('beginningOfTomorrow: ' + beginTomorrow);
gs.info('endOfTomorrow: ' + endTomorrow);
gs.info('beginningOfYesterday: ' + beginYesterday);
gs.info('endOfYesterday: ' + endYesterday);
gs.info('----------');
var gdt1 = new GlideDateTime(beginToday);
var gdt2 = new GlideDateTime(beginTomorrow);
var dur = GlideDateTime.subtract(gdt1, gdt2); //the difference between gdt1 and gdt2

gs.info('BeginTomorrow: ' + dur.getDisplayValue());

var gdt1 = new GlideDateTime(endToday);
var gdt2 = new GlideDateTime(endTomorrow);
var dur = GlideDateTime.subtract(gdt1, gdt2); //the difference between gdt1 and gdt2

gs.info('EndTomorrow: ' + dur.getDisplayValue());

var gdt1 = new GlideDateTime(beginToday);
var gdt2 = new GlideDateTime(beginYesterday);
var dur = GlideDateTime.subtract(gdt2, gdt1); //the difference between gdt1 and gdt2

gs.info('BeginningYesterday: ' + dur.getDisplayValue());

var gdt1 = new GlideDateTime(endToday);
var gdt2 = new GlideDateTime(endYesterday);
var dur = GlideDateTime.subtract(gdt2, gdt1); //the difference between gdt1 and gdt2

gs.info('EndYesterday: ' + dur.getDisplayValue());
```

**GlideSystem - endOfTomorrow()**

Retrieves the date and time for the end of tomorrow in GMT.
### GlideSystem - endOfTomorrow()

Gets the date and time for the end of tomorrow in GMT.

```javascript
var tomorrowEnd = new GlideDateTime();
tomorrowEnd.setValue(gs.endOfTomorrow());
```

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>

### GlideSystem - endOfYesterday()

Gets the date and time for the end of yesterday in GMT.

```javascript
var yesterdayEnd = new GlideDateTime();
yesterdayEnd.setValue(gs.endOfYesterday());
```

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format (yyyy-mm-dd hh:mm:ss).</td>
</tr>
</tbody>
</table>

### GlideSystem - eventQueue(String name, Object glideRecord, String parm1, String parm2, String queue)

Queues an event for the event manager.

```javascript
GlideSystem.eventQueue(String name, Object glideRecord, String parm1, String parm2, String queue);
```

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the event being queued.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glideRecord</td>
<td>Object</td>
<td>GlideRecord object, such as &quot;current&quot;.</td>
</tr>
<tr>
<td>parm1</td>
<td>String</td>
<td>(Optional) Saved with the instance if specified.</td>
</tr>
<tr>
<td>parm2</td>
<td>String</td>
<td>(Optional) Saved with the instance if specified.</td>
</tr>
<tr>
<td>queue</td>
<td>String</td>
<td>Name of the queue.</td>
</tr>
</tbody>
</table>

 Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
if (current.operation() != 'insert' && current.comments.changes()) {
    gs.eventQueue("incident.commented", current, gs.getUserID(), gs.getUserName());
}
```

Scoped equivalent

To use the `eventQueue()` method in a scoped application, use the corresponding scoped method: Scoped GlideSystem - eventQueue(String name, Object instance, String parm1, String parm2, String queue).

GlideSystem - eventQueueScheduled(String name, Object glideRecord, String parm1, String parm2, Object expiration)

Queues an event for the event manager at a specified date and time.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the event being queued.</td>
</tr>
<tr>
<td>glideRecord</td>
<td>Object</td>
<td>GlideRecord object, such as &quot;current&quot;.</td>
</tr>
<tr>
<td>parm1</td>
<td>String</td>
<td>(Optional) Saved with the instance if specified.</td>
</tr>
<tr>
<td>parm2</td>
<td>String</td>
<td>(Optional) Saved with the instance if specified.</td>
</tr>
<tr>
<td>expiration</td>
<td>Object</td>
<td>Date and time to process this event.</td>
</tr>
</tbody>
</table>
if (current.operation() != 'insert' && current.comments.changes()) {
    gs.eventQueueScheduled("incident.commented", current, gs.getUserID(), gs.getUserName(),
    new GlideDateTime('2018-06-02 20:00:00'));
}

Scoped equivalent

To use the `eventQueueScheduled()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - eventQueueScheduled(String name, Object instance, String parm1, String parm2, Object expiration)`.

GlideSystem - flushMessages()

Clears session messages saved using `addErrorMessage()` or `addInfoMessage()`.

Session messages are shown at the top of the form. In client side scripts, use `g_form.clearMessages()` to remove session messages.

GlideSystem - getAvatar()

Returns the file path to the user's avatar.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The file path to the user's avatar.</td>
</tr>
</tbody>
</table>

```javascript
var avatarFile = gs.getUser().getAvatar();
gs.addInfoMessage('User avatar ID: ' + avatarFile);
```

Output:

```
User avatar ID: c148ed13741310042106710ce41f149.iix?t=small
```

**GlideSystem - getCurrentScopeName()**

Returns the name of the current application scope.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Current scope name.</td>
</tr>
</tbody>
</table>

This example shows how to use `getCurrentScopeName()` to get the scope of the processor.

```javascript
var incident_GR = new GlideRecord('Incident');
if (incident_GR.get("2e3f6baddb9ad600added8f9618cb")) {
    gs.debug("processor scope = " + gs.getCurrentScopeName());
    var w = new global.Workflow();
```
Scoped equivalent

To use the `getCurrentScopeName()` method in a scoped application, use the corresponding scoped method: *Scoped GlideSystem - getCurrentScopeName()*.

**GlideSystem - getDisplayColumn(String tableName)**

Retrieves the display column for the table.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table from which to get the display column name.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Display column name</td>
</tr>
</tbody>
</table>

```javascript
// Return the sys_id value for a given table and its display value
function GetIDValue(table, displayValue) {
    var rec = new GlideRecord(table);
    var dn = gs.getDisplayColumn(table);
    if (rec.get(dn, displayValue))
        return rec.sys_id;
    else
        return null;
}
```

**GlideSystem - getDisplayValueFor(String tableName, String recordID, String fieldName)**

Returns the display value for a specified field on a specified record.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table.</td>
</tr>
<tr>
<td>recordID</td>
<td>String</td>
<td>Sys_id for the record.</td>
</tr>
<tr>
<td>fieldName</td>
<td>String</td>
<td>Name of the field whose display value to return.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Display value for the field.</td>
</tr>
</tbody>
</table>

This example shows how to use `getDisplayValueFor()` to return the display value of the `number` field.

```javascript
var value =
  gs.getDisplayValueFor(current.getTableName(), current.getValue('sys_id'), 'number');
```

### GlideSystem - getErrorMessages()

Returns the list of error messages for the session that were added by `addErrorMessage()`.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>List of error messages</td>
</tr>
</tbody>
</table>

This example shows how to parse through and pass back error messages using `getErrorMessages()`.

```javascript
MySessionUtil.getSessionError = function() {
  var msg = null;
  var msgs = gs.getErrorMessages().toArray();
  if (msgs.length > 0) {
```
Scoped equivalent

To use the `getErrorMessages()` method in a scoped application, use the corresponding scoped method: Scoped GlideSystem - `getErrorMessages()`.

GlideSystem - `getEscapedProperty(String key, Object substituteObject)`

Retrieves the property and escapes it for XML parsing.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Key for the property whose value should be returned.</td>
</tr>
<tr>
<td>substituteObject</td>
<td>Object</td>
<td>Optional. Object to return if the property is not found.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Property, or the substituteObject if the property is not found.</td>
</tr>
</tbody>
</table>

```javascript
var propValue = gs.getEscapedProperty("com.example.my_test_property");
gs.addInfoMessage("This is my property value " + propValue);
```

GlideSystem - `getImpersonatingUserDisplayName()`

Returns the display name of the impersonating user.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Display name of the impersonating user.</td>
</tr>
</tbody>
</table>

This example shows how to obtain the impersonator's user display name.

```javascript
var user = gs.getUserDisplayName();
gs.print("The current user display name is: " + user);

var name = gs.getImpersonatingUserDisplayName();
gs.print("Impersonating user display name: " + name);
```

Output:

The current user display name is: abel.tuter
Impersonating user display name: admin

**GlideSystem - getImpersonatingUserName()**

Returns the name of the impersonating user or null if not impersonating.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of impersonating user</td>
</tr>
</tbody>
</table>

This example shows how to obtain the impersonator's user name.

```javascript
var name = gs.getImpersonatingUserName();
var actual_user = null;
if (name == null || name == '')
    actual_user = user;
else
    actual_user = Packages.com.glide.sys.User.getUser(name);

var recent_impersonations = actual_user.getPreference('recent.impersonations');
var admin_role=actual_user.hasRole("admin");
```
GlideSystem - getInfoMessages()

Retrieves the list of info messages for the session that were added by addInfoMessage().

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>List of info messages.</td>
</tr>
</tbody>
</table>

This example shows how to obtain the information messages.

```javascript
var messages = gs.getInfoMessages();
if (messages.toString().indexOf('Conflicts Detected') == -1)
    gs.addInfoMessage(msg);
```

GlideSystem - getInitials()

Returns the user's initials.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The user's initials.</td>
</tr>
</tbody>
</table>

```javascript
var userInitials = gs.getUser().getInitials();
gs.addInfoMessage('User initials: ' + userInitials);
```

Output:

User initials: SA
**GlideSystem - getMessage(String messageID, Object args)**

Retrieves translated messages from the Message [sys_ui_message] table to display in a UI.

If the specified message identifier (key) exists in the Message [sys_ui_message] table for the current language, the method returns the translated message. If the specified message identifier does not exist for the current language, the method returns the English version of the message. If the message identifier does not exist in the table, then it returns the message ID.

For additional information about the Message table, see [Message table](#).

硭 Note: If the UI message has a tick ('), there may be issues with the message in the script; to escape the ticks ('), use `getMessageS(String, Object)`.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>messageID</td>
<td>String</td>
<td>Message identifier. You can locate this value in the Key field of the Message [sys_ui_message] table. Note the Key field may look exactly like the actual message string.</td>
</tr>
<tr>
<td>args</td>
<td>Object</td>
<td>Optional. List of strings or other values defined by java.text.MessageFormat that replace the variables within the specified message. For example: <code>gs.getMessage(&quot;Abort adding action '{0}', same subflow can't be added twice in this subflow.&quot;, current.action.name);</code> In this example '{0}' is replaced with the content of current.action.name.</td>
</tr>
</tbody>
</table>

硭 Note: The passed in values are not translated. They are inserted verbatim in the message.

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Requested UI message.</td>
</tr>
</tbody>
</table>

This example shows the message returned for the current user when Spanish is the current language.
```javascript
var my_message = gs.getMessage("rows will not be updated");
alert(my_message);
```

Output

```
las filas no se actualizarán
```

This example shows how to replace a single variable within a message.

```javascript
// current.action.name is "update record"
var my_message = gs.getMessage("Abort adding action '{0}', same subflow can't be added twice in this subflow.", current.action.name);
alert(my_message);
```

Output

```
Abort adding action update record, same subflow can't be added twice in this subflow.
```

This example shows how to replace multiple variables within a message.

```javascript
// current.sub_flow.name is 'schedule users'
// current.action.name is "update record"
var my_message = gs.getMessage("Abort adding action '{0}', same subflow can't be added twice in {1} subflow.", [current.action.name, current.sub_flow.name]);
alert(my_message);
```

Output

```
Abort adding action update record, same subflow can't be added twice in schedule users subflow.
```

**Scoped equivalent**

To use the `getMessage()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - getMessage(String id, Array args)**.

**GlideSystem - getMessageS(String messageId, Object args)**

Retrieves translated messages to display in the UI and escapes all ticks (').

If the specified message identifier (key) exists in the Message [sys_ui_message] table for the current language, the method returns the translated message. If the specified message identifier does not exist for the current language, the method returns the English version of the message. If the message identifier does not exist in the table, then it returns the message ID.

For additional information about the Message table, see Message table.

Useful if you are inserting into a JavaScript expression from Jelly.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MessageID</td>
<td>String</td>
<td>Message identifier. You can locate this value in the Key field of the Message [sys_ui_message] table. Note the Key field may look exactly like the actual message string.</td>
</tr>
<tr>
<td>args</td>
<td>Object</td>
<td>Optional. List of strings or other values defined by java.text.MessageFormat that replace the variables within the specified message. For example: gs.getMessage(&quot;Abort adding action '{0}', same subflow can't be added twice in this subflow.&quot;, current.action.name); In this example '{0}' is replaced with the content of current.action.name.</td>
</tr>
</tbody>
</table>

**Note:** The passed in values are not translated. They are inserted verbatim in the message.

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Specified message with ticks escaped.</td>
</tr>
</tbody>
</table>

```java
/*
"I love France" translates to "J'aime la France" in French.
Rendering this without escaping the tick in "J'aime" would break Jelly, because the tick would prematurely end the variable assignment, and everything that follows (aime la France') would be a jelly syntax error.
*/
var my_message = '${gs.getMessageS("I love France")}';
alert(my_message);
```

Output:

J'aime la France

---

**GlideSystem** - **getNodeValue(Object obj, Number index)**

Returns the node value for the specified index.
function doInsert(nodeList) {
    gs.print('Doing insert');
    var task = new GlideRecord('task');
    task.initialize();
    for (var x=0; x < nodeList.size(); x++) {
        var name = gs.getNodeName(nodeList, x);
        var value = gs.getNodeValue(nodeList, x);
        task.setValue(name, value);
    }
    task.insert();
}

GlideSystem - getNodeName(Object obj, Number index)
Returns the node name for the specified index.

function doInsert(nodeList) {
    gs.print('Doing insert');
    var task = new GlideRecord('task');
    task.initialize();
    for (var x=0; x < nodeList.size(); x++) {
        var name = gs.getNodeName(nodeList, x);
        var value = gs.getNodeValue(nodeList, x);
        task.setValue(name, value);
    }
    task.insert();
}

GlideSystem - getNodeName(Object obj, Number index)
Returns the node name for the specified index.

function doInsert(nodeList) {
    gs.print('Doing insert');
    var task = new GlideRecord('task');
    task.initialize();
    for (var x=0; x < nodeList.size(); x++) {
        var name = gs.getNodeName(nodeList, x);
        var value = gs.getNodeValue(nodeList, x);
        task.setValue(name, value);
    }
    task.insert();
}

GlideSystem - getNodeName(Object obj, Number index)
Returns the node name for the specified index.
function doInsert(nodeList) {
  gs.print('Doing insert');
  var task = new GlideRecord('task');
  task.initialize();
  for (var x=0; x < nodeList.size(); x++) {
    var name = gs.getNodeName(nodeList, x);
    var value = gs.getNodeValue(nodeList, x);
    task.setValue(name, value);
  }
  task.insert();
}

GlideSystem - getPreference(String key, Object default)
Returns the specified user preference.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Key for the preference.</td>
</tr>
<tr>
<td>default</td>
<td>Object</td>
<td>Default value to use if the specified preference is not found.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Preference value. If no preference, returns the specified default value.</td>
</tr>
</tbody>
</table>

function getSelectedProject() {
  var array= new Array();
  var prj_id = gs.getPreference("prj_id"); //This will fetch value from user preference
  var gr = new GlideRecord('pm_project_task');
  gr.addQuery('parent', prj_id);
  gr.addActiveQuery();
  while(gr.next()) {
    array.push(gr.sys_id.toString());
  }
  return array;
}
GlideSystem - getProperty(String key, Object alt)

Returns the value of a Glide property. If the property is not found, returns the specified alt value.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>Key for the property whose value should be returned.</td>
</tr>
<tr>
<td>alt</td>
<td>Object</td>
<td>Optional. Alternate object to return if the property is not found.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value of the Glide property, or the alternate object defined above.</td>
</tr>
</tbody>
</table>

//Check for attachments and add link if there are any
var attachment_link = '';
var rec = new GlideRecord('sc_req_item');
rec.addQuery('sys_id', current.request_item);
rec.query();
if(rec.next()){
  if(rec.hasAttachments()){
    attachment_link = gs.getProperty('glide.servlet.uri') + rec.getLink();
  }
}

GlideSystem - getScriptError(String script)

Returns the script error found in the specified script, if there is one.

Note: The script is not executed by this function, it is only checked for syntax errors.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>script</td>
<td>String</td>
<td>Script to check for errors.</td>
</tr>
</tbody>
</table>
**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Error message. Null if there is no error.</td>
</tr>
</tbody>
</table>

```java
if (gs.isValidScript(current.script) == false)
{
    current.setAbortAction(true);
    var error = gs.getScriptError(current.script);
    current.script.setError(error);
}
```

**GlideSystem - getSession()**

Returns a GlideSession object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideSession Object</td>
<td>GlideSession object for the current session</td>
</tr>
</tbody>
</table>

```java
if (!gs.hasRole("admin") && gs.getSession().isInteractive() && gs.getUserName() != "guest"){
    var qc = current.addQuery('u_visibility', "both");
    qc.addOrCondition('u_visibility', '');
    if (gs.getImpersonatingUserName() != null) {
        gs.getSession().clearClientData('navQuery');
    }
    var navQuery = gs.getSession().getClientData('navQuery');
    if (navQuery == null) {
        var isManager = gs.getUser().getRecord().getValue('u_is_manager');
        if (!isManager) {
            qc.addOrCondition('u_visibility', 'nonmanager');
            gs.getSession().putClientData('navQuery', 'nonmanager');
        } else {
            qc.addOrCondition('u_visibility', 'manager');
            gs.getSession().putClientData('navQuery', 'manager');
        }
    }
}
```
Scoped equivalent
To use the `getSession()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - getSession()**.

**GlideSystem - getSessionID()**

Returns the GlideSession session ID.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Session ID</td>
</tr>
</tbody>
</table>

```javascript
var gr_NOW = new GlideRecord('v_user_session');
var sessionId = gs.getSessionID();
gs.log("Session ID is: " + sessionId);
```

**Output**

```
Session ID is: FEE589B3DB7EE4103DD9C39D139619D7
```

Scoped equivalent
To use the `getSessionID()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - getSessionID()**.

**GlideSystem - getStyle(String tableName, String fieldName, String fieldValue)**

Returns the style defined for the table, field, and field value.
### GlideSystem - getUser()

Returns a reference to the user object for the current user.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideUser</td>
<td>Reference to a user object for the current user.</td>
</tr>
</tbody>
</table>

The following example shows how to get the current user object.

```javascript
var user = gs.getUser();
gs.print("The current user is: " + user);
```

**Output:**

```
The current user is: com.glide.sys.User@db5dd9
```

The following example shows how to check whether the current user has the workflow_admin role.
var role = gs.getUser().hasRole('workflow_admin');
gs.print("Does the current user have the workflow_admin role: "+role);

Output:
Does the current user have the workflow_admin role: true

Scoped equivalent
To use the `getUser()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - getUser().**

GlideSystem - getUserDisplayName()
Returns the name field of the current user. For example, the API returns John Smith instead of jsmith.

| Parameters | | |
|------------|---------------------------------|
| None       | | |

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

The following example shows how to get the current user's display name.

```javascript
var user = gs.getUserDisplayName();
gs.print("The current user display name is: "+user);
```

Output:
The current user display name is: abel.tuter

Scoped equivalent
To use the `getUserDisplayName()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - getUserDisplayName().**

GlideSystem - getUserID()
Returns the sys_id of the current user.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id of the current user.</td>
</tr>
</tbody>
</table>

This example gets the current user's sys_id.

```javascript
var currentUserId = gs.getUserID();
gs.print("Current user ID: "+currentUserId);
```

Output:

Current user ID: 6816f79cc0a8016401c5a33be04be441

Scoped equivalent

To use the `getUserID()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - getUserID()**.

**GlideSystem - getUserName()**

Returns the name of the current user, such as jsmith.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>User name of the current user.</td>
</tr>
</tbody>
</table>

The following example shows how to get the current user's display name object.

```javascript
var user = gs.getUserName();
gs.print("The current user name is: "+user);
```
```javascript
var impUser = new GlideImpersonate();
impUser.impersonate("62826bf03710200044e0bfc8bcbe5df1");
var user = gs.getUserName();
gs.print("The impersonated user name is: " + user);
```

**Output:**

The current user name is: admin
The impersonated user name is: abel.tuter

**Scoped equivalent**

To use the `gs.getUserName()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - getUserName().**

**GlideSystem - getUserNameByUserID(String user_id)**

Returns the user name based on a user ID.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_id</td>
<td>String</td>
<td>User ID of the user whose user name to return.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of the user.</td>
</tr>
</tbody>
</table>

The following example shows how to get the specified user's display name.

```javascript
var displayName = gs.getUserNameByUserID('abel.tuter');
gs.info('User display name is: ' + displayName);
```

**Output:**

User display name is: Abel Tuter

**GlideSystem - getXMLNodeList(String xml)**

Constructs an array of all the nodes and values in an XML document.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml</td>
<td>String</td>
<td>XML document to parse.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array list</td>
<td>List of names and values of the outer most XML node.</td>
</tr>
</tbody>
</table>

The following example shows how to get a list of XML nodes and their associated values in an array list.

```javascript
var nodeList =
gs.getXMLNodeList("<note><to>Tove</to><from>Jani</from><heading>Reminder</heading><body>Don't forget me this weekend!</body></note>"; gs.print("The node contains: " + nodeList);
```

**Output:**

The node contains: [to : Tove, from : Jani, heading : Reminder, body : Don't forget me this weekend!]

---

**GlideSystem - getXMLText(String xml, String xpathQuery)**

Returns the XML text for the first element in the XML string that matches the XPath query.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml</td>
<td>String</td>
<td>XML string to search.</td>
</tr>
<tr>
<td>xpathQuery</td>
<td>String</td>
<td>XPath query to match.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>XML node matching the search parameters.</td>
</tr>
</tbody>
</table>

The following example shows how to get the value of a specified XML element within a passed-in node.
var nodeList =
gs.getXMLText("<outer><note><to>Tove</to><from>Jani</from><heading>Reminder</heading><body>
Don't forget me this weekend!</body></note></outer>", "//from");
gs.print ("The from element contains: " + nodeList);

Output:
The from element contains: Jani

**GlideSystem - hasRole(String roleName)**

Determines if the current user has at least one of the passed-in roles.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roleName</td>
<td>String</td>
<td>Comma-separated list of roles.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the current user has at least one of the specified roles. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: User has at least one of the passed-in roles. Also returns true if the user has the administrator role.</td>
</tr>
<tr>
<td></td>
<td>• false: User does not have any of the passed-in roles.</td>
</tr>
</tbody>
</table>

The following example shows how to check whether the current user has the admin or groups_admin role.

```javascript
if (!gs.hasRole("admin, groups_admin") && gs.getSession().isInteractive()) {
    var qc = current.addQuery("u_hidden", ",!-",",true"); //cannot see hidden groups...
    qc.addOrCondition("sys_id", "javascript:gteMyGroups()"); //...unless in the hidden group
}
```

**Scoped equivalent**

To use the `hasRole()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - hasRole(Object role)**.

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
**GlideSystem - hasRoleInGroup(Object roleName, Object group)**

Determines if the current user has the specified role within a specified group.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>roleName</td>
<td>Object</td>
<td>Name of the role.</td>
</tr>
<tr>
<td>group</td>
<td>Object</td>
<td>Sys_id of the group to check for the specified role.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the current user has the specified role in the specified group. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: If all of the following conditions are met.</td>
</tr>
<tr>
<td></td>
<td>◦ The logged-in user is assigned to the specified role.</td>
</tr>
<tr>
<td></td>
<td>◦ The granted by field on the user role record is set to the specified group.</td>
</tr>
<tr>
<td></td>
<td>◦ The inherited field on the user role record is false.</td>
</tr>
<tr>
<td></td>
<td>• false: If any one of the conditions above are not met.</td>
</tr>
</tbody>
</table>

The following example shows how to check whether the sys_user_group group has the role_name role.

```javascript
var group = new GlideRecord('sys_user_group');
group.addQuery('name', 'GROUP_NAME');
group.setLimit(1);
group.query();
if (group.next()) {
    if (gs.hasRoleInGroup('role_name', group)) {
        gs.print('User has role in group');
    } else {
        gs.print('User does NOT have role in group');
    }
}
```
GlideSystem - hoursAgo(Number hours)

Returns a date and time for the specified number of hours ago. The returned value is adjusted for the time zone of the instance.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hours</td>
<td>Number</td>
<td>Number of hours ago.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>UTC date and time for the specified number of hours ago. Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

```javascript
var currentDateTime = gs.hoursAgo(0);
gs.info("Current date/time: " + currentDateTime);

var agoDateTime = gs.hoursAgo(1);
gs.info("Ago date/time: " + agoDateTime);
```

Output

Current date/time: 2021-03-17 20:53:25
Ago date/time: 2021-03-17 19:53:25

Scoped equivalent

To use the `hoursAgo()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - hoursAgo(Number hours)`.

GlideSystem - hoursAgoEnd(Number hours)

Returns a date and time for the end of the hour for the specified number of hours ago. The returned value is adjusted for the time zone of the instance.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hours</td>
<td>Number (Integer)</td>
<td>Number of hours ago.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>UTC date and time for the end of the specified number of hours ago. Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

```javascript
var currentDateTime = gs.hoursAgoEnd(0);
gs.print("Current date/time: " + currentDateTime);

var agoDateTime = gs.hoursAgoEnd(1);
gs.print("Ago date/time: " + agoDateTime);
```

Output

Current date/time: 2021-03-17 20:59:59
Ago date/time: 2021-03-17 19:59:59

Scoped equivalent

To use the `hoursAgoEnd()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - hoursAgoEnd(Number hours)**.

**GlideSystem - hoursAgoStart(Number hours)**

Returns a date and time for the start of the hour for the specified number of hours ago. The returned value is adjusted for the time zone of the instance.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hours</td>
<td>Number</td>
<td>Number of hours ago.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>UTC date and time for the end of the specified number of hours ago. Format: yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

```javascript
var currentDateTime = gs.hoursAgoStart(0);
gs.print("Current date/time: " + currentDateTime);
```
var agoDateTime = gs.hoursAgoStart(1);
gs.print("Ago date/time: " + agoDateTime);

Output

Current date/time: 2021-03-17 20:00:00
Ago date/time: 2021-03-17 19:00:00

Scoped equivalent

To use the `hoursAgoStart()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - hoursAgoStart(Number hours)`.

GlideSystem - isFirstOfMonth(Object date)

Checks whether the date in the specified date object is the first day of the month.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>Object</td>
<td>Date object on which to check the date, such as GlideDateTime or GlideDate.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean  | Flag that indicates whether the date in the specified date object is the first day of the month. Possible values:  
  • true: First day of the month.  
  • false: Not the first day of the month. |

This example show how to determine whether the date in the specified date object is the first day of the month.

```javascript
var gdt = new GlideDateTime();
gdt.setValue('2021-04-01 12:00:00');
var currentDay = gs.isFirstOfMonth(gdt);
gs.print("First day of month: " + currentDay);
```
gdt.setValue('2021-04-21 12:00:00');
var currentDay = gs.isFirstDayOfMonth(gdt);
gs.print("First day of month: " + currentDay);

Output
First day of month: true
First day of month: false

GlideSystem - isFirstDayOfWeek(Object date)
Checks whether the date in the specified date object is the first day of the week. This method uses the ISO standard of Monday being the first day of the week.

Parameters
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>Object</td>
<td>Date object on which to check the date, such as GlideDateTime or GlideDate.</td>
</tr>
</tbody>
</table>

Returns
<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the date in the current date object is the first day of the week (Monday). Possible values: • true: First day of the week. • false: Not the first day of the week.</td>
</tr>
</tbody>
</table>

This example show how to determine whether the date in the specified date object is the first day of the week.

```javascript
var gdt = new GlideDateTime();
gdt.setValue('2021-03-02 12:00:00');
var currentDay = gs.isFirstDayOfWeek(gdt);
gs.info("First day of week: " + currentDay);

gdt.setValue('2021-03-22 12:00:00');
var currentDay = gs.isFirstDayOfWeek(gdt);
gs.info("First day of week: " + currentDay);
```

Output
First day of week: false
First day of week: true
GlideSystem - isFirstDayOfYear(Object date)
Checks whether the date in the specified date object is the first day of the year.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>Object</td>
<td>Date object on which to check the date, such as GlideDateTime or GlideDate.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the date in the specified date object is</td>
</tr>
<tr>
<td></td>
<td>the first day of the year.</td>
</tr>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: First day of the year.</td>
</tr>
<tr>
<td></td>
<td>• false: Not the first day of the year.</td>
</tr>
</tbody>
</table>

This example show how to determine whether the date in the specified date object is the first day of the year.

```javascript
var gdt = new GlideDateTime();
gdt.setValue('2020-12-31 12:00:00');
var currentDay = gs.isFirstDayOfYear(gdt);
gs.info("First day of year: "+ currentDay);

gdt.setValue('2021-01-01 12:00:00');
var currentDay = gs.isFirstDayOfYear(gdt);
gs.info("First day of year: "+ currentDay);
```

Output

First day of year: false
First day of year: true

GlideSystem - isInteractive()
Checks if the current session is interactive.
An example of an interactive session is when a user logs in using the log-in screen. An example of a non-interactive session is using a SOAP request to retrieve data.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates whether the session is interactive. Possible values:  
• true: Session is interactive.  
• false: Session is not interactive. |

```javascript
if (!gs.hasRole('admin') && gs.isInteractive()) {
    var qc1 = current.addQuery('u_group', '');
    var gra = new GlideRecord('sys_user_grmember');
    gra.addQuery('user', gs.getUserID());
    gra.query();
    while (gra.next()) {
        qc1.addOrCondition('u_group', gra.group);
    }
}
```

### Scoped equivalent

To use the `isInteractive()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - isInteractive()`.

### GlideSystem - isLastDayOfMonth(Object date)

Checks whether the date in the specified date object is the last day of the month.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>Object</td>
<td>Date object on which to check the date, such as GlideDateTime or GlideDate.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean | Flag that indicates whether the date in the specified date object is the last day of the month. Possible values:  
  • true: Last day of the month.  
  • false: Not the last day of the month. |

This example show how to determine whether the date in the specified date object is the last day of the month.

```javascript
var gdt = new GlideDate();
gdt.setValue('2020-12-31 12:00:00');
var currentDay = gs.isLastDayOfMonth(gdt);
gs.print("First day of year: " + currentDay);

gdt.setValue('2021-01-01 12:00:00');
var currentDay = gs.isLastDayOfMonth(gdt);
gs.print("First day of year: " + currentDay);
```

**Output**

```
Last day of month: true
Last day of month: false
```

### GlideSystem - isLastDayOfWeek(Object date)

Checks whether the date in the specified date object is the last day of the week. This method uses the ISO standard of Sunday being the last day of the week.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>Object</td>
<td>Date object on which to check the date, such as GlideDateTime or GlideDate.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean  | Flag that indicates whether the date in the current date object is the last day of the week (Sunday). Possible values:  
  • true: Last day of the week.  
  • false: Not the last day of the week. |

This example shows how to determine whether the date in the specified date object is the last day of the week.

```javascript
var gdt = new GlideDate();
gdt.setValue('2021-03-01 12:00:00');
var currentDay = gs.isLastDayOfWeek(gdt);
gs.info("Last day of week: " + currentDay);

gdt.setValue('2021-03-21 12:00:00');
var currentDay = gs.isLastDayOfWeek(gdt);
gs.info("Last day of week: " + currentDay);
```

**Output**

First day of week: false

First day of week: true

### GlideSystem - isLastDayOfYear(Object date)

Checks whether the date in the specified date object is the last day of the year.
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean  | Flag that indicates whether the date in the current date object is the last day of the year. Possible values:  
| • true: Last day of the year.  
| • false: Not the last day of the year. |

This example show how to determine whether the date in the specified date object is the last day of the year.

```javascript
var gdt = new GlideDateTime();
gdt.setValue('2020-12-31 12:00:00');
var currentDay = gs.isLastDayOfYear(gdt);
gs.info("Last day of year: " + currentDay);

gdt.setValue('2021-01-01 12:00:00');
var currentDay = gs.isLastDayOfYear(gdt);
gs.info("Last day of year: " + currentDay);
```

Output

```
Last day of year: true
Last day of year: false
```

**GlideSystem - isLoggedIn()**

Determines if the current user is currently logged in.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean  | Flag that indicates whether the current user is logged in. Possible values:  
|          |                                                                             |
Returns (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• true:</td>
<td>User is logged in.</td>
</tr>
<tr>
<td>• false:</td>
<td>User is not logged in.</td>
</tr>
</tbody>
</table>

This example shows how to determine whether the current user is logged in.

```java
if (gs.isLoggedIn())
    gs.info("Current user is logged in");
else
    gs.info("Current user is NOT logged in");
```

Output

```
Current user is logged in
```

**Scoped equivalent**

To use the `isLoggedIn()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - isLoggedIn()`.

**GlideSystem - isMobile()**

Determines whether the request came from a mobile device.

You can use this method in UI action conditions and business rules.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the request came from a mobile device. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Mobile device.</td>
</tr>
<tr>
<td></td>
<td>• false: Non-mobile device.</td>
</tr>
</tbody>
</table>
This example shows how to determine whether the current device is a mobile device.

```javascript
if(gs.isMobile())
    gs.info("Submitted from mobile UI");
else
    gs.info("NOT submitted from mobile UI");
```

**Output**

Submitted from mobile UI

**Scoped equivalent**

To use the `isMobile()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - isMobile()`.

**GlideSystem - lastWeek()**

Returns the date and time one week ago in GMT.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>String</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

This example shows how to obtain the date that is one week from the date in the current date object.

```javascript
var gdt = new GlideDateTime();
gdt.setValue('2021-03-22 01:00:00');

gs.info("Current date: " + gs.nowDateTime());
gs.info("One week earlier: " + gs.lastWeek());
```

**Output**
GlideSystem - log(String message, String source)
Logs a message to the system log and saves it to the syslog table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Message to log.</td>
</tr>
<tr>
<td>source</td>
<td>String</td>
<td>Optional. Source of the message.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example shows how to post a log entry using constants and variables.

```javascript
var count = new GlideAggregate('incident');
count.addQuery('active', 'true');
count.addAggregate('COUNT', 'category');
count.query();
while (count.next()) {
    var category = count.category;
    var categoryCount = count.getAggregate('COUNT', 'category');
    gs.log("The are currently " + categoryCount + " incidents with a category of " + category, "Incident Counter");
}
```

GlideSystem - logError(String message, String source)
Logs an error to the system log and saves it to the syslog table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Error message to log.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>String</td>
<td>Optional. Source of the message.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example logs an error if the Incident table cannot be found.

```javascript
var gr_NOW = new GlideRecord("incident");
if (!gr_NOW.isValid()) {
    gs.logError('Incident table could not be found');
    return;
}
```

**GlideSystem - logWarning(String message, String source)**

Logs a warning to the system log and saves it to the syslog table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Message to log.</td>
</tr>
<tr>
<td>source</td>
<td>String</td>
<td>Optional. Source of the message.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

The following example logs a warning if the Incident table cannot be found.

```javascript
var gr_NOW = new GlideRecord("incident");
if (!gr_NOW.isValid()) {
    gs.logWarning('Incident table could not be found');
    return;
}
```
**GlideSystem - minutesAgo(Number minutes)**

Returns a date and time for the specified number of minutes ago.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>minutes</td>
<td>Number</td>
<td>Number of minutes in the past to return.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>UTC date and time for the specified number of minutes ago.</td>
</tr>
<tr>
<td></td>
<td>Format: <code>yyyy-mm-dd hh:mm:ss</code></td>
</tr>
</tbody>
</table>

This example shows how to use the minutesAgo() method in an addQuery() call.

```java
// Check to see if the user has failed to login too many times
// when the limit is reached, lock the user out of the system
//
// Check failed logins in the last 15 minutes
var now_GR = new GlideRecord('sysevent');
now_GR.addQuery('name', 'login.failed');
now_GR.addQuery('parm1', event.parm1.toString());
now_GR.addQuery('sys_created_on', '>=', gs.minutesAgo(15));
now_GR.query();
var rowCount = now_GR.getRowCount();
if(rowCount >= 5){
    var now_GR = new GlideRecord("sys_user");
    now_GR.addQuery("user_name", event.parm1.toString());
    now_GR.query();
    if (now_GR.next()) {
        now_GR.locked_out = true;
        now_GR.update();
        gs.log("User " + event.parm1 + " locked out due to too many invalid login attempts");
    }
}
```

**GlideSystem - minutesAgoEnd(Number minutes)**

Returns a date and time for the end of the minute a certain number of minutes ago.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>minutes</td>
<td>Number</td>
<td>An integer number of minutes</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the `minutesAgoEnd()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - minutesAgoEnd(Number minutes)`.

**GlideSystem - minutesAgoStart(Number minutes)**

Returns a date and time for the start of the minute a certain number of minutes ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>minutes</td>
<td>Number</td>
<td>An integer number of minutes</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the `minutesAgoStart()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - minutesAgoStart(Number minutes)`.

**GlideSystem - monthsAgo(Number months)**

Returns a date and time for a certain number of months ago.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>An integer number of months</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT on today's date of the specified month, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the `monthsAgo()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - monthsAgo(Number months)`.

`GlideSystem - monthsAgoEnd(Number months)`

Returns a date and time for the last day of the month a certain number of months ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>An integer number of months</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT end of the month the specified number of months ago, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

`GlideSystem - monthsAgoStart(Number months)`

Returns a date and time for the start of the month a certain number of months ago.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>An integer number of months</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT start of the month the specified number of months ago, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

### Scoped equivalent

To use the `monthsAgoStart()` method in a scoped application, use the corresponding scoped method: **Scoped GlideSystem - monthsAgoStart(Number months)**.

### GlideSystem - nil(Object obj)

Queries an object and returns true if the object is null or contains an empty string.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>obj</td>
<td>Object</td>
<td>The object to be checked.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if null or empty string; otherwise, false.</td>
</tr>
</tbody>
</table>

```javascript
if (!current.u_date1.nil() && !current.u_date2.nil()) {
    var start = current.u_date1.getGlideObject().getNumericValue();
    var end = current.u_date2.getGlideObject().getNumericValue();
    if (start > end) {
        gs.addInfoMessage('start must be before end');
        current.u_date1.setError('start must be before end');
        current.setAbortAction(true);
    }
}
```
Scoped equivalent

To use the `nil()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - nil(Object o)`.

**GlideSystem - now()**

Returns the current date in UTC.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The current date in the user-defined format, in UTC.</td>
</tr>
</tbody>
</table>

```javascript
// When the user password changes then set the u_password_last_reset field
// to now so we know when to force another update
var now_GR = new GlideRecord("sys_user");
if (now_GR.get(event.parm1.toString())) {
    // Do something based on the Password Changing
    gs.log("The user password changed so do something else...");
    now_GR.u_password_last_reset = gs.now();
    now_GR.update();
}
```

**GlideSystem - nowNoTZ()**

Returns the current date and time in UTC format.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The current UTC date time</td>
</tr>
</tbody>
</table>

// When the user password changes then set the u_password_last_reset field
// to now so we know when to force another update

var now GR = new GlideRecord("sys_user");
if (now GR.get(event.parm1.toString())) {
    // Do something based on the Password Changing
    gs.log("The user password changed so do something else...");
    now GR.u_password_last_reset = gs.nowNoTZ();
    now GR update();
}

GlideSystem - nowDateTime()

Returns the current date and time in the user-defined format.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Current date and time in the user-defined format. For more information on setting the system date and time format, see Date and Date/Time fields.</td>
</tr>
</tbody>
</table>

var currentDate Time = gs.nowDateTime();

gs.print("Current date/time: " + currentDate Time);

Output

Current date/time: 2021-03-17 14:04:02
When setting a variable in a workflow script to the current date and time, use the `setDisplayValue()` method. The following script sets the workflow variable `end_date` to the current date and time.

```
current.variables.end_date.setDisplayValue(gs.nowDateTime());
```

**GlideSystem - nowGlideDateTime()**

Gets a GlideDateTime object with the current date and time.

After you get a GlideDateTime object with the current date and time, you can use the GlideDateTime methods to perform date-time operations, such as performing date-time calculations, formatting a date-time, or converting between date-time formats.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>Object</td>
</tr>
</tbody>
</table>

Sets the field `u_target_date` to the current date and time in GMT format.

```
current.u_target_date = gs.nowGlideDateTime();
```

**GlideSystem - print(String message)**

Writes a message to the system log.

This method does not write the message to the syslog table unless debug has been activated.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>message</td>
</tr>
</tbody>
</table>
void

var rec = new GlideRecord('incident');
rec.addQuery('active',false);
rec.query();
while (rec.next()) {
  gs.print('Inactive incident ' + rec.number + ' deleted');
  rec.deleteRecord();
}

GlideSystem - quartersAgo(Number quarters)
Returns a date and time for a certain number of quarters ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>quarters</td>
<td>Number</td>
<td>An integer number of quarters</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of the quarter that was the specified number of quarters ago, in the format yyyy-mm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>

GlideSystem - quartersAgoEnd(Number quarters)
Returns a date and time for the last day of the quarter, for a specified number of quarters ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>quarters</td>
<td>Number</td>
<td>An integer number of quarters</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT end of the quarter that was the specified number of quarters ago, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the `quartersAgoEnd()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - quartersAgoEnd(Number quarters)`.

**GlideSystem - quartersAgoStart(Number quarters)**

Returns a date and time for the first day of the quarter, for a specified number of quarters ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>quarters</td>
<td>Number</td>
<td>An integer number of quarters</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT end of the month that was the specified number of quarters ago, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the `quartersAgoStart()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - quartersAgoStart(Number quarters)`.

**GlideSystem - setProperty(String key, String value, String description)**

Sets the specified key to the specified value.
**Note:** Care should be taken when setting system properties (sys_properties) using this method as it causes a system-wide cache flush. Each flush can cause system degradation while the caches rebuild. If a value must be updated often, it should not be stored as a system property. In general, you should only place values in the sys_properties table that do not frequently change.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>The key for the property to be set.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The value of the property to be set.</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>A description of the property.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
gs.setProperty("glide.foo","bar","foo");
gs.info(gs.getProperty("glide.foo"));
```

Output: bar

**Scoped equivalent**

To use the `setProperty()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - setProperty(String key, String value, String description)`.

### GlideSystem - setRedirect(Object URI)

Sets the redirect URI for this transaction, which then determines the next page the user will see.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URI</td>
<td>Object</td>
<td>URI to set as the redirect</td>
</tr>
</tbody>
</table>
This example redirects the user to a particular catalog item, and passes along the current email as a parameter.

```java
gs.setRedirect("com.glideapp.servicecatalog_cat_item_view.do?sysparm_id=d41ce5bac611227a0167f4bf8109bf70&sysparm_user="+
current.sys_id + "+&sysparm_email=" + current.email)
```

**Scoped equivalent**

To use the `setRedirect()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - setRedirect(Object o)`.

**GlideSystem - setReturn(Object URI)**

Sets the return URI for this transaction. This determines what page the user will be directed to when they return from the next form.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URI</td>
<td>Object</td>
<td>URI to set as the return location.</td>
</tr>
</tbody>
</table>

This example ensures that the user will be returned to the current page when they are done with the next one.

```java
gs.setReturn (current.getLink(true));
```

**GlideSystem - tableExists(String tableName)**

Determines if a database table exists.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>Name of the table</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the table exists, false otherwise.</td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the `tableExists()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - tableExists(String name)`.

**GlideSystem - userID()**

Returns the sys_id of the user associated with this session. Use `getUserID()` instead.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>sys_id of the current user</td>
</tr>
</tbody>
</table>

**GlideSystem - workflowFlush(Object glideRecord)**

Deletes any open scheduled job records in the Schedule (sys_trigger) table for the specified GlideRecord.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glideRecord</td>
<td>Object</td>
<td>The GlideRecord</td>
</tr>
</tbody>
</table>
GlideSystem - yearsAgo(Number years)

Gets a date and time for a certain number of years ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>years</td>
<td>Number</td>
<td>An integer number of years</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of the year that is the specified number of years ago, in the format yyyy-mm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>

Scoped equivalent

To use the yearsAgo(Number years) method in a scoped application, use the corresponding scoped method: Scoped GlideSystem - yearsAgo(Number years).

GlideSystem - yesterday()

Returns yesterday's time (24 hours ago).

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT for 24 hours ago, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>
Scoped equivalent

To use the `yesterday()` method in a scoped application, use the corresponding scoped method: `Scoped GlideSystem - yesterday()`.

GlideSystem - Scoped

The scoped GlideSystem (referred to by the variable name 'gs' in any server-side JavaScript) API provides a number of convenient methods to get information about the system, the current logged in user, etc.

Many of the GlideSystem methods facilitate the easy inclusion of dates in query ranges, and are most often used in filters and reporting.

Scoped GlideSystem - addErrorMessage(String message)

Adds an error message for the current session.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>message</td>
<td>String</td>
<td>Message to add.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
gs.include("PrototypeServer");
var ValidatePasswordStronger = Class.create();
ValidatePasswordStronger.prototype = {
    process : function() {
        var user_password = request.getParameter("user_password");
        var min_len = 8;
        var rules = "Password must be at least " + min_len + " characters long and contain a digit, an uppercase letter, and a lowercase letter.";
        if (user_password.length() < min_len) {
            gs.addErrorMessage("TOO SHORT: " + rules);
            return false;
        }
        var digit_pattern = new RegExp("[0-9]", "g");
        if (!digit_pattern.test(user_password)) {
            gs.addErrorMessage("DIGIT MISSING: " + rules);
        }
    }
};
```
return false;
}
var upper_pattern = new RegExp("[A-Z]", "g");
if (!upper_pattern.test(user_password)) {
    gs.addErrorMessage("UPPERCASE MISSING: " + rules);
    return false;
}
var lower_pattern = new RegExp("[a-z]", "g");
if (!lower_pattern.test(user_password)) {
    gs.addErrorMessage("LOWERCASE MISSING: " + rules);
    return false;
}
return true; // password is OK
}

Scoped GlideSystem - addInfoMessage(String message)
Adds an info message for the current session. This method is not supported for asynchronous business rules.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Info message to add.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
Scoped GlideSystem - base64Encode(String source)
Creates a base64 string from the specified string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>String</td>
<td>String to encode.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Encoded base64 string.</td>
</tr>
</tbody>
</table>

Example

```java
var mac = new CertificateEncryption;
var key = "sample_key";
key = gs.base64Encode(key);
mac.generateMac(key, "HmacSHA256", "sample_data");
```

Scoped GlideSystem - base64Decode(String source)
Returns an ASCII string from the specified base64 string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>String</td>
<td>A base64 encoded string.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The decoded string.</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - beginningOfLastMonth()
Returns the date and time for the beginning of last month in GMT.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of last month, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - beginningOfLastWeek()

Returns the date and time for the beginning of last week in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of last week, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - beginningOfNextMonth()

Returns the date and time for the beginning of next month in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of next month, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>
Scoped GlideSystem - beginningOfWeek()
Returns the date and time for the beginning of next week in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The GMT beginning of next week, in the format yyyy-mm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - beginningOfYear()
Returns the date and time for the beginning of next year in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of next year, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - beginningOfMonth()
Returns the date and time for the beginning of this month in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of next year, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of this month, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - beginningOfThisQuarter()

Returns the date and time for the beginning of this quarter in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of this quarter, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - beginningOfThisWeek()

Returns the date and time for the beginning of this week in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of this week, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - beginningOfThisYear()

Returns the date and time for the beginning of this year in GMT.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td>String</td>
<td>Format: yyyy-mm-dd</td>
</tr>
<tr>
<td>range</td>
<td>String</td>
<td>Start, end, or a time in the 24 hour format hh:mm:ss.</td>
</tr>
</tbody>
</table>

**Scoped GlideSystem - daysAgo(Number days)**

Returns the date and time for a specified number of days ago.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>Number</td>
<td>Integer number of days</td>
</tr>
</tbody>
</table>
function contractNoticeDue() {
    var now_GR = new GlideRecord("contract");
    now_GR.addQuery("u_contract_status", "Active");
    now_GR.query();
    while (now_GR.next()) {
        if ((now_GR.u_termination_date <= gs.daysAgo(-90)) && (now_GR.u_contract_duration == "Long")) {
            now_GR.u_contract_status = "In review";
        } else if ((now_GR.u_termination_date <= gs.daysAgo(-50)) &&
            (now_GR.u_contract_duration == "Medium")) {
            now_GR.u_contract_status = "In review";
        } else if ((now_GR.u_termination_date <= gs.daysAgo(-10)) &&
            (now_GR.u_contract_duration == "Short")) {
            now_GR.u_contract_status = "In review";
        }
    }
    now_GR.update();
}

Scoped GlideSystem - daysAgoEnd(Number days)
Returns the date and time for the end of the day a specified number of days ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>Number</td>
<td>Integer number of days</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT end of the day in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>
Scoped GlideSystem - daysAgoStart(Number days)

Returns the date and time for the beginning of the day a specified number of days ago.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>days</td>
<td>String</td>
<td>Integer number of days</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT start of the day in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord('sysapproval_approver');
now_GR.addQuery('state', 'requested');
now_GR.addQuery('sys_updated_on', '<', gs.daysAgoStart(5));
now_GR.query();
```

Scoped GlideSystem - debug(String message, Object parm1, Object parm2, Object parm3, Object parm4, Object parm5)

Writes a debug message to the system log.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>The log message with place holders for any variable arguments.</td>
</tr>
<tr>
<td>parm1</td>
<td>Object</td>
<td>(Optional) First variable argument.</td>
</tr>
<tr>
<td>parm2</td>
<td>Object</td>
<td>(Optional) Second variable argument.</td>
</tr>
<tr>
<td>parm3</td>
<td>Object</td>
<td>(Optional) Third variable argument.</td>
</tr>
<tr>
<td>parm4</td>
<td>Object</td>
<td>(Optional) Fourth variable argument.</td>
</tr>
<tr>
<td>parm5</td>
<td>Object</td>
<td>(Optional) Fifth variable argument.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
gs.debug("This is a debug message");
var myFirstName = "Abel";
var myLastName = "Tuter";
gs.debug("This is a debug message from {0}.{1}", myFirstName, myLastName);
```

Output:

This is a debug message (sys.scripts extended logging)
This is a debug message from Abel.Tuter (sys.scripts extended logging)

**Scoped GlideSystem - endOfLastMonth()**

Returns the date and time for the end of last month in GMT.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT end of last month, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

**Scoped GlideSystem - endOfLastWeek()**

Returns the date and time for the end of last week in GMT.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT end of last week, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

 Scoped GlideSystem - endOfLastYear()

Returns the date and time for the end of last year in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

 Scoped GlideSystem - endOfNextMonth()

Returns the date and time for the end of next month in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

 Scoped GlideSystem - endOfNextWeek()

Returns the date and time for the end of next week in GMT.
### Scoped GlideSystem - endOfNextYear()

Returns the date and time for the end of next year in GMT.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

### Scoped GlideSystem - endOfThisMonth()

Returns the date and time for the end of this month in GMT.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>
Scoped GlideSystem - endOfThisQuarter()

Returns the date and time for the end of this quarter in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - endOfThisWeek()

Returns the date and time for the end of this week in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - endOfThisYear()

Returns the date and time for the end of this year in GMT.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - error(String message, Object parm1, Object parm2, Object parm3, Object parm4, Object parm5)

Writes an error message to the system log.

This method accepts up to five variable arguments (varargs) in the message using the Java MessageFormat placeholder replacement pattern.

Note: Variables must contain valid values for this method to provide correct output.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>The log message with place holders for any variable arguments.</td>
</tr>
<tr>
<td>param1</td>
<td>Object</td>
<td>(Optional) First variable argument.</td>
</tr>
<tr>
<td>param2</td>
<td>Object</td>
<td>(Optional) Second variable argument.</td>
</tr>
<tr>
<td>param3</td>
<td>Object</td>
<td>(Optional) Third variable argument.</td>
</tr>
<tr>
<td>param4</td>
<td>Object</td>
<td>(Optional) Fourth variable argument.</td>
</tr>
<tr>
<td>param5</td>
<td>Object</td>
<td>(Optional) Fifth variable argument.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
gs.error("This is an error message");
var myFirstName = "Abel";
var myLastName = "Tuter";
gs.error("This is an error message from {0}.{1}", myFirstName, myLastName);
```

Output:
This is an error message
This is an error message from Abel.Tuter

Scoped GlideSystem - eventQueue(String name, Object instance, String parm1, String parm2, String queue)

Queues an event for the event manager.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the event being queued.</td>
</tr>
<tr>
<td>instance</td>
<td>Object</td>
<td>GlideRecord object, such as &quot;current&quot;.</td>
</tr>
<tr>
<td>parm1</td>
<td>String</td>
<td>Optional. Saved with the instance if specified.</td>
</tr>
<tr>
<td>parm2</td>
<td>String</td>
<td>Optional. Saved with the instance if specified.</td>
</tr>
<tr>
<td>queue</td>
<td>String</td>
<td>Optional. Name of the queue.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

if (current.operation() != 'insert' && current.comments.changes()) {
    gs.eventQueue('incident.commented', current, gs.getUserID(), gs.getUserName());
}

Scoped GlideSystem - eventQueueScheduled(String name, Object instance, String parm1, String parm2, Object expiration)

Queues an event in the event manager.

The passed in event schedule information is stored in the Events [sysevent] table. For additional information on events, see Events.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the event to queue.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>Object/ String</td>
<td>GlideRecord object or the sys_id of the record to which this event applies.</td>
</tr>
<tr>
<td>parm1</td>
<td>String</td>
<td>Optional. String to pass into the event script. This parameter is free-form and depends on the implementation of the event script. Default: If the instance parameter is a GlideRecord object, then the default is the display value for that GlideRecord (now_GR.getDisplayValue) otherwise it is null.</td>
</tr>
<tr>
<td>parm2</td>
<td>String</td>
<td>Optional. String to pass into the event script. This parameter is free-form and depends on the implementation of the event script. Default: null</td>
</tr>
<tr>
<td>expiration</td>
<td>Object</td>
<td>Optional. GlideDateTime object or a date/time type element that specifies the date and time to process the event. Default: Current date/time</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to call the method using a GlideRecord, two parameters that are passed to the event script, and a specified time to schedule the event.

```javascript
var requestXml = requestBody.dataString;
var processTime = new GlideDateTime();
processTime.addDaysLocalTime(7);
gs.eventQueueScheduled('sn_app.user.deactivate', now_GR, requestXML, gs.getUserID(), processTime);
```

This example shows how to call the method using a sys_id and the default values for the optional parameters.

```javascript
gs.eventQueueScheduled('event.test', '0e29421383101000dada83ec37d9292d', '', '', '');
```
Scoped GlideSystem - executeNow(GlideRecord job)
Executes a job for a scoped application.
You can only use this method on a job in the same application as the script calling this method.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job</td>
<td>GlideRecord</td>
<td>Job to run.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Returns the sys_id of the scheduled job. Returns null if the job is global.</td>
</tr>
</tbody>
</table>

Example

```javascript
scheduleImportJob: function () {
    var jobId = '61847fe04c603300fa9bb64c2b491dac';
    var now_GR = new GlideRecord('sysauto_script');
    if (!now_GR.get(jobId)) {
        throw new Error('Unable to find import job');
    }
    gs.executeNow(now_GR);
}
```

Scoped GlideSystem - generateGUID()
Generates a GUID that can be used when a unique identifier is required.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A 32-character hexadecimal GUID.</td>
</tr>
</tbody>
</table>
personalId = gs.generateGUID();
gs.info(personalId);

Output: af770511ff013100e04bfffffffff6

**Scoped GlideSystem - getCallerScopeName()**

Gets the caller scope name; returns null if there is no caller.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The caller's scope name, or null if there is no caller.</td>
</tr>
</tbody>
</table>

This example shows two script includes that are set to Accessible from all application scopes. One script include is created within app_scope_a.

```javascript
var Scopea = Class.create();

Scopea.prototype = {
  initialize: function() {
  },

  callerScope: function() {
    var scopeb = new app_scope_b.Scopeb();
    return scopeb.callerscope();
  },

  type: 'Scopea'
}
```

Output:

This example shows another script include created within app_scope_b.

```javascript
var Scopeb = Class.create();

Scopeb.prototype = {
  initialize: function() {
```
```javascript
this._constructorCallerScope = gs.getCallerScopeName();

callerscope: function() {
    return gs.getCallerScopeName();
},

getConstructorCallerScope: function() {
    return this._constructorCallerScope;
},

type: 'Scopeb'
```

Output:

This script can be used within scope app_scope_a to get the scope name of the caller—in this case app_scope_b.

```javascript
gs.info(new Scopea().getCallerScopeName());
```

**Scoped GlideSystem - getCssCacheVersionString()**

Gets a string representing the cache version for a CSS file.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The CSS cache version.</td>
</tr>
</tbody>
</table>

```javascript
var verStr = gs.getCssCacheVersionString();
gs.info(verStr);
```

Output: _d82979516f0171005be8883e6b3ee4cf&theme=

**Scoped GlideSystem - getCurrentApplicationId()**

Gets the ID of the current application as set using the Application Picker.
**Scoped GlideSystem - getCurrentApplicationId()**

Gets the current application's sys_id, or global in none is set.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var currentId = gs.getCurrentApplicationId();
gs.info(currentId);
```

Output: `04936cb16f30b1005be8883e6b3ee4e0`

**Scoped GlideSystem - getCurrentScopeName()**

Gets the name of the current scope.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var currentScope = gs.getCurrentScopeName();
gs.info(currentScope);
```

**Scoped GlideSystem - getErrorMessages()**

Returns the error messages that were added by `addErrorMessage()` for the session.

```javascript
var errorMessage = gs.getErrorMessages();
gs.info(errorMessage);
```
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array of Strings</td>
<td>Error messages associated with the session.</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - getEscapedMessage(String id, Array args)

Retrieves the specified message from the Message [sys_ui_message] table. If the message has HTML special characters, replaces them with the corresponding HTML name codes. For example, & becomes &amp;.

If the specified message identifier (Key) exists in the Message [sys_ui_message] table for the current language, the method returns the translated message with all special characters returned as escape sequences. If the specified message identifier does not exist for the current language, then the method returns the English version of the message with all special characters returned as escape sequences. If the message identifier does not exist in the table, then it returns the message ID.

For additional information about the Message table, see Message table.

Note: If the UI message has a tick (‘), there may be issues with the message in the script; to escape the ticks (‘), use getMessageS(String, Object).

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>Message identifier. You can locate this value in the Key field of the Message [sys_ui_message] table. Note the Key field may look exactly like the actual message string.</td>
</tr>
<tr>
<td>args</td>
<td>Array</td>
<td>Optional. List of strings or other values defined by java.text.MessageFormat that replace the variables within the specified message. For example: gs.getMessage(&quot;Abort adding action '{0}', same subflow can't be added twice in this subflow.&quot;, current.action.name);</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>In this example '{0}' is replaced with the content of <code>current.action.name</code>.</td>
</tr>
</tbody>
</table>

⚠ **Note:** The passed in values are not translated. They are inserted verbatim in the message.

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>UI message with HTML special characters replaced with HTML name codes.</td>
</tr>
</tbody>
</table>

This example shows the ampersand character being replaced with the equivalent ampersand HTML name code.

```javascript
var my_message = gs.getEscapedMessage("Is the summary & details accurate?");
alert(my_message);
```

Output

Is the summary &amp; details accurate?

This example shows how to replace a single variable within a message and how the `<` and `>` symbols in the message are transposed to the corresponding HTML name codes of `&lt` and `&gt`.

```javascript
// current.action.name is "update record"
var my_message = gs.getEscapedMessage("Abort adding action '{0}', same <subflow> can't be added twice in this subflow.", current.action.name);
alert(my_message);
```

Output

Abort adding action update record, same &ltsubflow&gt can't be added twice in this subflow.

### Scoped GlideSystem - getMessage(String id, Array args)

Retrieves translated messages from the Message [sys_ui_message] table to display in a UI.

If the specified message identifier (key) exists in the Message [sys_ui_message] table for the current language, then the method returns the translated message.
If the specified message identifier does not exist for the current language, then the method returns the English version of the message. If the message identifier does not exist in the table, then it returns the message ID.

For additional information about the Message table, see Message table

Note: If the UI message has a tick ('), there may be issues with the message in the script; to escape the ticks ('), use getMessages(String, Object).

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>String</td>
<td>Message identifier. You can locate this value in the Key field of the Message [sys_ui_message] table. Note the Key field may look exactly like the actual message.</td>
</tr>
<tr>
<td>args</td>
<td>Array</td>
<td>Optional. List of strings or other values defined by java.text.MessageFormat that replace the variables within the specified message. For example: gs.getMessage(&quot;Abort adding action '{0}', same subflow can't be added twice in this subflow.&quot;, current.action.name); In this example '{0}' is replaced with the content of current.action.name. Note: The passed in values are not translated. They are inserted verbatim in the message.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>UI message.</td>
</tr>
</tbody>
</table>

This example shows the message returned for the current user when Spanish is the current language.

```javascript
var my_message = gs.getMessage("rows will not be updated");
alert(my_message);
```

Output

```
las filas no se actualizarán
```

This example shows how to replace a single variable within a message.
// current.action.name is "update record"
var my_message = gs.getMessage("Abort adding action '{0}', same subflow can't be added
twice in this subflow.", current.action.name);
alert(my_message);

Output
Abort adding action update record, same subflow can't be added twice in this subflow.

This example shows how to replace multiple variables within a message.

// current.sub_flow.name is 'schedule users'
// current.action.name is "update record"
var my_message = gs.getEscapedMessage("Abort adding action '{0}', same subflow can't be
added twice in {1} subflow.", [current.action.name, current.sub_flow.name]);
alert(my_message);

Output
Abort adding action update record, same subflow can't be added twice in schedule users
subflow.

Scoped GlideSystem - getProperty(String key, Object alt)

Gets the value of a Glide property. If the property is not found, returns an alternate value.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>The key for the property whose value should be returned.</td>
</tr>
<tr>
<td>alt</td>
<td>Object</td>
<td>(Optional) Alternate object to return if the property is not found.</td>
</tr>
</tbody>
</table>

var attachment_link = gs.getProperty('glide.servlet.uri');
gs.info(attachment_link);

Output: https://instance.service-now.com/
Scoped GlideSystem - getSession()

Gets a reference to the current Glide session.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A reference for the current session.</td>
</tr>
</tbody>
</table>

```javascript
if (!gs.hasRole("admin") && !gs.hasRole("user_admin") && gs.getSession().isInteractive()) {
    current.addQuery("active", "true");
}
```

Scoped GlideSystem - getSessionID()

Retrieves the GlideSession session ID.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The session ID.</td>
</tr>
</tbody>
</table>

```javascript
var myUserObject = gs.getSessionID();
gs.info(myUserObject);
```

Output:

A0D4E5416F3F21005BE8883E6B3EE4B8
Scoped GlideSystem - getSessionToken()

This method is no longer available. Instead, use gs.getSession().getSessionToken().

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The session token.</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - getTimeZoneName()

Returns the name of the time zone associated with the current user.

This method has been deprecated. Instead, use the Scoped GlideSession - getTimeZoneName() method in the GlideSession API.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The time zone name.</td>
</tr>
</tbody>
</table>

gs.info(gs.getTimeZoneName());

Scoped GlideSystem - getUrlOnStack()

Gets the current URI for the session.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The URI.</td>
</tr>
</tbody>
</table>

```javascript
gs.info(gs.getUrlOnStack());
```

Scoped GlideSystem - getUser()

Returns a reference to the scoped GlideUser object for the current user.

See GlideUser - Scoped for a list of available methods.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideUser</td>
<td>Reference to a scoped user object.</td>
</tr>
</tbody>
</table>

```javascript
var myUserObject = gs.getUser();
```

Scoped GlideSystem - getUserDisplayName()

Gets the display name of the current user.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>-------</td>
<td>-----------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>String</td>
<td>The name field of the current user. Returns Abel Tuter, as opposed to abel.tuter.</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
gs.info(gs.getUserDisplayName());
```

**Scoped GlideSystem - getUserID()**

Gets the sys_id of the current user.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

```javascript
gs.info(gs.getUserID());
```

**Scoped GlideSystem - getUserName()**

Gets the user name, or user id, of the current user.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

```javascript
gs.info(gs.getUserName());
```
Scoped GlideSystem - hasRole(Object role)
Determines if the current user has the specified role.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>role</td>
<td>Object</td>
<td>The role to check.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the user had the role. Returns true for users with the administrator role.</td>
</tr>
</tbody>
</table>

```java
if (!gs.hasRole("admin") && !gs.hasRole("groups_admin") && gs.getSession().isInteractive()) {
    var qc = current.addQuery("u_hidden", "!=" , "true"); // cannot see hidden groups...
    qc.addOrCondition("sys_id", "javascript:getMyGroups()" ); // ... unless in the hidden group
    gs.info("User has admin and groups admin roles");
} else {
    gs.info("User does not have both admin and groups admin roles");
}
```

Scoped GlideSystem - hoursAgo(Number hours)
Returns the date and time for a specified number of hours ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hours</td>
<td>Number</td>
<td>Integer number of hours</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>
if (current.operation() == 'insert') {
    // If no due date was specified, calculate a default
    if (current.due_date == '') {
        if (current.urgency == '1') {
            // Set due date to 4 hours ahead of current time
            current.due_date = gs.hoursAgo(-4);
        }
        if (current.urgency == '2') {
            // Set due date to 2 days ahead of current time
            current.due_date = gs.daysAgo(-2);
        }
        if (current.urgency == '3') {
            // Set due date to 7 days ahead of current time
            current.due_date = gs.daysAgo(-7);
        }
    }
}

Scoped GlideSystem - hoursAgoEnd(Number hours)
Returns the date and time for the end of the hour a specified number of hours ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hours</td>
<td>Number</td>
<td>Integer number of hours</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - hoursAgoStart(Number hours)
Returns the date and time for the start of the hour a specified number of hours ago.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hours</td>
<td>Number</td>
<td>Integer number of hours</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - include(String name)

Provides a safe way to call a script include from the sandbox, allowing only the inclusion of trusted scripts.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the script to include.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean| Flag that indicates whether the script include worked. Possible values:
|        | • true: Script include worked. |
|        | • false: Script include failed. |

This example gets the LDAPUtils in the current script context.

```javascript
var ldapServer = new GlideRecord("ldap_server_config");
ldapServer.addActiveQuery();
ldapServer.query();
gs.include("LDAPUtils");
var ldapUtils = new LDAPUtils();
var errMsg = "";
while (ldapServer.next()) {
   var ldap = new GlideLDAP();
   var dn = ldapServer.dn;
   var env = ldap.setup();
```
if (env == null) {
    errMsg = "Failed environment setup, missing URL";
    gs.eventQueue("ldap.connection_failed", ldapServer, ldapServer.getDisplayValue(), errMsg);
    gs.logError("LDAP server " + ldapServer.getDisplayValue() + " failed scheduled connection test: " + errMsg, "LDAP");
}

Scoped GlideSystem - info(String message, Object parm1, Object parm2, Object parm3, Object parm4, Object parm5)

Writes an info message to the system log.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>The log message with place holders for any variable arguments.</td>
</tr>
<tr>
<td>param1</td>
<td>Object</td>
<td>(Optional) First variable argument.</td>
</tr>
<tr>
<td>param2</td>
<td>Object</td>
<td>(Optional) Second variable argument.</td>
</tr>
<tr>
<td>param3</td>
<td>Object</td>
<td>(Optional) Third variable argument.</td>
</tr>
<tr>
<td>param4</td>
<td>Object</td>
<td>(Optional) Fourth variable argument.</td>
</tr>
<tr>
<td>param5</td>
<td>Object</td>
<td>(Optional) Fifth variable argument.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

gs.info("This is an info message");
var myFirstName = "Abel";
var myLastName = "Tuter";
gs.info("This is an info message from {0}.{1}", myFirstName, myLastName);

Output:

This is an info message
This is an info message from Abel.Tuter
Scoped GlideSystem - isDebugging()

Determines if debugging is active for a specific scope.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if either session debugging is active or the log level is set to debug for the specified scope.</td>
</tr>
</tbody>
</table>

```javascript
gs.debug("This is a log message");
var myFirstName = "Abel";
var myLastName = "Tuter";
gs.debug("This is a log message from {0}.{1}", myFirstName, myLastName);
gs.info(gs.isDebugging());
```

Scoped GlideSystem - isInteractive()

Checks if the current session is interactive. An example of an interactive session is when a user logs in normally. An example of a non-interactive session is using a SOAP request to retrieve data.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the session is interactive.</td>
</tr>
</tbody>
</table>

```javascript
if (!gs.hasRole("admin") && gs.getSession().isInteractive()) {
    var qc1 = current.addQuery('u_group','');
    var gra = new GlideRecord('sys_user_grmember');
    gra.addQuery('user', gs.getUserID());
```
gra.query();
while (gra.next()) {
    qc1.addOrCondition('u_group', gra.group);
}

Scoped GlideSystem - isLoggedIn()
Determines if the current user is currently logged in.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the current user is logged in.</td>
</tr>
</tbody>
</table>

gs.info(gs.isLoggedIn());

Scoped GlideSystem - isMobile()
You can determine if a request comes from a mobile device.

This method can be used in UI action conditions and business rules.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the request comes from a mobile device; otherwise, false.</td>
</tr>
</tbody>
</table>

if (gs.isMobile())
    gs.info("submitted from mobile UI");
else
  gs.info("NOT submitted from mobile UI");

Scoped GlideSystem - monthsAgo(Number months)
Returns the date and time for a specified number of months ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>Integer number of months</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT on today's date of the specified month, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - minutesAgoEnd(Number minutes)
Returns the date and time for the end of the minute a specified number of minutes ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>minutes</td>
<td>Number</td>
<td>Integer number of minutes</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - minutesAgoStart(Number minutes)
Returns the date and time for the start of the minute a specified number of minutes ago.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>minutes</td>
<td>Number</td>
<td>Integer number of minutes</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - monthsAgoStart(Number months)

Returns the date and time for the start of the month a specified number of months ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>months</td>
<td>Number</td>
<td>Integer number of months</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT start of the month the specified number of months ago, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - nil(Object o)

Queries an object and returns true if the object is null, undefined, or contains an empty string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>o</td>
<td>Object</td>
<td>The object to be checked.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the object is null, undefined, or contains an empty string; otherwise, returns false.</td>
</tr>
</tbody>
</table>

```javascript
var now_GR = new GlideRecord();
gs.info(gs.nil(now_GR));
```

Scoped GlideSystem - quartersAgoEnd(Number quarters)

Returns the date and time for the last day of the quarter for a specified number of quarters ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>quarters</td>
<td>Number</td>
<td>Integer number of quarters</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT end of the quarter that was the specified number of quarters ago, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - quartersAgoStart(Number quarters)

Returns the date and time for the first day of the quarter for a specified number of quarters ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>quarters</td>
<td>Number</td>
<td>Integer number of quarters</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT end of the month that was the specified number of quarters ago, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

**Scoped GlideSystem - setProperty(String key, String value, String description)**

Sets the specified key to the specified value if the property is within the script's scope.

**Note:** Care should be taken when setting system properties (sys_properties) using this method as it causes a system-wide cache flush. Each flush can cause system degradation while the caches rebuild. If a value must be updated often, it should not be stored as a system property. In general, you should only place values in the sys_properties table that do not frequently change.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>String</td>
<td>The key for the property to be set.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>The value of the property to be set.</td>
</tr>
<tr>
<td>description</td>
<td>String</td>
<td>A description of the property.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
gs.setProperty("glide.foo","bar","foo");
gs.info(gs.getProperty("glide.foo"));
```

Output: bar

**Scoped GlideSystem - setRedirect(Object o)**

Sets the redirect URI for this transaction, which then determines the next page the user will see.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>o</td>
<td>Object</td>
<td>URI object or URI string to set as the redirect</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
gs.setRedirect("com.glideapp.servicecatalog_cat_item_view.do?sysparm_id=d41ce5bac61227a0167f4bf8109bf70=sysparm_user=" + current.sys_id + "&sysparm_email=" + current.email)
```

### Scoped GlideSystem - tableExists(String name)

Determines if a database table exists.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the table to check for existence.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the table exists. False if the table was not found.</td>
</tr>
</tbody>
</table>

```java
gs.info(gs.tableExists('incident'));
```

### Scoped GlideSystem - urlEncode(String url)

Encodes non-ASCII characters, unsafe ASCII characters, and spaces so the returned string can be used on the Internet. Uses UTF-8 encoding. Uses percent (%) encoding.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>The string to be encoded.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A string with non-ASCII characters, unsafe ASCII characters, and spaces encoded.</td>
</tr>
</tbody>
</table>

**Scoped GlideSystem - urlDecode(String url)**

Replaces UTF-8 encoded characters with ASCII characters.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>String</td>
<td>A string with UTF-8 percent (%) encoded characters.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A string with encoded characters replaced with ASCII characters.</td>
</tr>
</tbody>
</table>

**Scoped GlideSystem - warn(String message, Object parm1, Object parm2, Object parm3, Object parm4, Object parm5)**

Writes a warning message to the system log.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>The log message with place holders for any variable arguments.</td>
</tr>
<tr>
<td>param1</td>
<td>Object</td>
<td>(Optional) First variable argument.</td>
</tr>
<tr>
<td>param2</td>
<td>Object</td>
<td>(Optional) Second variable argument.</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>param3</td>
<td>Object</td>
<td>(Optional) Third variable argument.</td>
</tr>
<tr>
<td>param4</td>
<td>Object</td>
<td>(Optional) Fourth variable argument.</td>
</tr>
<tr>
<td>param5</td>
<td>Object</td>
<td>(Optional) Fifth variable argument.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
gs.warn("This is a warning");
var myFirstName = "Abel";
var myLastName = "Tuter";
gs.warn("This is a warning from {0}.{1}", myFirstName, myLastName);
```

**Output:**

```
This is a warning
This is a warning from Abel.Tuter
```

### Scoped GlideSystem - xmlToJSON(String xmlString)

Takes an XML string and returns a JSON object.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlString</td>
<td>String</td>
<td>The XML string to be converted.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>A JSON object representing the XML string. Null if unable to process the XML string.</td>
</tr>
</tbody>
</table>

```javascript
var jsonObject = gs.xmlToJSON(xmlString);
```
Scoped GlideSystem - yearsAgo(Number years)

Returns a date and time for a certain number of years ago.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>years</td>
<td>Number</td>
<td>An integer number of years</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT beginning of the year that is the specified number of years ago, in the format yyyy-mm-dd hh:mm:ss.</td>
</tr>
</tbody>
</table>

Scoped GlideSystem - yesterday()

Returns yesterday's time (24 hours ago).

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>GMT for 24 hours ago, in the format yyyy-mm-dd hh:mm:ss</td>
</tr>
</tbody>
</table>

GlideSystemRunLevel API - Global

Provides methods to get and set the current system run level.

Setting the system run level allows applications to change or limit their features based on operational toggles. For more information about using operational toggles, see Operational toggles.

The system run level can be set to one of the defined system run levels.

- Fully Operational
- Slightly Degraded
• Moderately Degraded
• Severely Degraded

The system run level set on one node is synchronized to all nodes in the instance. The admin role is required to use this API.

**GlideSystemRunLevel – getCurrentLevel()**

Retrieves the current system run level.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Gets the current system run level.

```javascript
var currentRunLevel = sn_run_level.GlideSystemRunLevel.getCurrentLevel();
gs.info(currentRunLevel);
```

Output:

```
fully_operational
```

**GlideSystemRunLevel – switchLevel(String newLevel)**

Switches the system run level.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>newLevel</td>
<td>String</td>
<td>The ID value of the new system run level. This value is from the ID field in the System Run Level [sys_run_level] table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>ID of the previous system run level. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• fully_operational</td>
</tr>
<tr>
<td></td>
<td>• slightly_degraded</td>
</tr>
<tr>
<td></td>
<td>• moderately_degraded</td>
</tr>
<tr>
<td></td>
<td>• severely_degraded</td>
</tr>
</tbody>
</table>

Sets the system run level to Slightly Degraded.

```
sn_run_level.GlideSystemRunLevel.switchLevel('slightly_degraded');
```

Output:

```
SystemRunLevel requested to change from: fully_operational to: slightly_degraded
```

**GlideTableHierarchy - Scoped**

The Scoped GlideTableHierarchy API provides methods for handling information about table relationships.

**Scoped GlideTableHierarchy - getAllExtensions()**

Returns an array of strings containing all tables that extend the current table and includes the current table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

| Type   | Description                                                                
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of strings containing the tables in the hierarchy that includes</td>
</tr>
<tr>
<td></td>
<td>the current table.</td>
</tr>
</tbody>
</table>

var table = new GlideTableHierarchy("task");
gs.info(table.getAllExtensions());

Output: Line breaks added for clarity.

task, sc_task, problem_task, change_phase, sc_req_item, kb_submission, release_phase, problem, ticket, sm_task, hr_task, change_task, change_request, change_request_imac, incident, release_task, vtb_task, sm_order, hr_case, sysapproval_group, sc_request

**Scoped GlideTableHierarchy - getBase()**

Returns the parent class.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The parent class.</td>
</tr>
</tbody>
</table>

var table = new GlideTableHierarchy("cmdb_ci_server");
gs.info(table.getBase());

Output:

cmdb_ci_computer

**Scoped GlideTableHierarchy - getHierarchy()**

Returns an array of strings containing all classes in the hierarchy of the current table.
**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of strings of the classes in the hierarchy.</td>
</tr>
</tbody>
</table>

```javascript
var table = new GlideTableHierarchy("incident");
gs.info(table.getHierarchy());
```

Output:

```
incident,task
```

**Scoped GlideTableHierarchy - getName()**

Returns the table's name.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The table's name.</td>
</tr>
</tbody>
</table>

```javascript
var table = new GlideTableHierarchy("incident");
gs.info(table.getName());
```

Output:

```
incident
```

**Scoped GlideTableHierarchy - getRoot()**

Returns the top level class in the hierarchy.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Name of the root class.</td>
</tr>
</tbody>
</table>

```javascript
var table = new GlideTableHierarchy("cmdb_ci_server");
gs.info(table.getRoot());
```

Output:

```javascript
cmdb
```

**Scoped GlideTableHierarchy - getTables()**

Returns an array of strings of the table names in the hierarchy.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of strings containing the names of tables in the hierarchy.</td>
</tr>
</tbody>
</table>

```javascript
var table = new GlideTableHierarchy("incident");
gs.info(table.getTables());
```

Output:

```javascript
incident, task
```

**Scoped GlideTableHierarchy - getTableExtensions()**

Returns an array of strings containing all tables that extend the current table.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>An array of strings containing the tables that extend the current table.</td>
</tr>
</tbody>
</table>

```javascript
var table = new GlideTableHierarchy("task");
gs.info(table.getTableExtensions());
```

**Output:** Line breaks added for clarity

```
sc_task,problem_task,change_phase,sc_req_item,kb_submission,release_phase,problem, 
ticket,sm_task,hr_task,change_task,change_request,change_request_imac,incident, 
release_task,vtb_task,sm_order/hr_case/sysapproval_group/sc_request
```

### Scoped GlideTableHierarchy - GlideTableHierarchy(String tableName)

Instantiates a GlideTableHierarchy object.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tableName</td>
<td>String</td>
<td>The name of the table.</td>
</tr>
</tbody>
</table>

```javascript
var table = new GlideTableHierarchy("incident");
gs.info(table.getTables());
```

**Output:**

```
incident,task
```

### Scoped GlideTableHierarchy - isBaseClass()

Returns true if this is a base class.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the current table has no parent and has extensions.</td>
</tr>
</tbody>
</table>

```javascript
var table = new GlideTableHierarchy("incident");
gs.info(table.isBaseClass());
```

Output:

false

Scoped GlideTableHierarchy - isSoloClass()

Returns true if this table is not in a hierarchy.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the current table has no parent and no extensions.</td>
</tr>
</tbody>
</table>

```javascript
var table = new GlideTableHierarchy("sys_user");
gs.info(table.isSoloClass());
```

Output:

true

Scoped GlideTableHierarchy - hasExtensions()

Returns true if this class has been extended.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the current table has extensions.</td>
</tr>
</tbody>
</table>

```javascript
var table = new GlideTableHierarchy("incident");
gs.info(table.hasExtensions());
```

Output:

```
false
```

**GlideTextReader - Scoped**

Provides the ability to read single lines from an input stream. Because an input stream is used, it is not subject to the 5MB attachment size limit.

**Scoped GlideTextReader - getEncoding()**

Returns the character encoding of the input stream.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The character encoding of the input stream.</td>
</tr>
</tbody>
</table>

**Scoped GlideTextReader - GlideTextReader(GlideScriptableInputStream inputStream)**

Creates a scoped GlideTextReader object for the specified input stream.
## GlideScriptableInputStream

The input stream to be read.

### GlideTextReader - readLine()

Returns a single line from the input stream and returns a string. Since this is working off of a stream, it is not subject to the 5MB size limit.

### GlideTime - Scoped

The scoped GlideTime class provides methods for performing operations on GlideTime objects, such as instantiating GlideTime objects or working with GlideTime fields.

### Scoped GlideTime - getByFormat(String format)

Returns the time in the specified format.

For information on the time formats that you can pass into this method, see Global date and time field format. You can pass these values in any order and add separators such as a dash, space, backslash, or colon. In addition, you can also pass the character "a" to return am/pm.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| format | String | String to use to format the time. For example, if the current time is 10:30:20 then:  
- hh:mm:ss = 10:30:20  
- HH = 10  
- HH — ss = 10 — 20  
- hh a = 10 AM  
- s:m:H ss:mm:hh = 20:30:10 20:30:10  
- HH:mm:ss.SSSZ = 10:30:20.000+0000  
- HH/mm/ss = 10/30/20 |

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Time in the specified format.</td>
</tr>
</tbody>
</table>

```javascript
var gt = new GlideTime();
gt.setValue('12:00:00');
gs.info(gt.getByFormat("HH:mm"));
```

Output:

```
12:00
```

Scoped GlideTime - getDisplayValue()

Gets the time in the current user's display format and time zone.

When designing business rules or script includes remember that this method may return values in different formats for different users.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The time in the user's format and time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gt = new GlideTime();
gt.setDisplayValue("12:00:00"); // User Time Zone
gs.info(gt.getDisplayValue()); // User Time Zone
```

Scoped GlideTime - getDisplayValueInternal()

Gets the display value in the current user's time zone and the internal format (HH:mm:ss).

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The time value for the GlideTime object in the current user's time zone and the internal time format of HH:mm:ss.</td>
</tr>
</tbody>
</table>

```javascript
var gt = new GlideTime();
gt.setValue("01:00:00"); //Internal Time Zone , UTC
gs.info(gt.getDisplayValueInternal()); //User Time Zone
```

Scoped GlideTime - getHourLocalTime()

Returns the hours part of the time using the local time zone.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Returns</td>
<td></td>
<td></td>
</tr>
<tr>
<td>---------</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
<td></td>
</tr>
<tr>
<td>Number</td>
<td>The hours using the local time zone.</td>
<td></td>
</tr>
</tbody>
</table>

**Scoped GlideTime - getHourOfDayLocalTime()**

Returns the hours part of the time using the local time zone. The number of hours is based on a 24 hour clock.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The hours using the local time zone. The number of hours is based on a 24 hour clock.</td>
</tr>
</tbody>
</table>

**Scoped GlideTime - getHourOfDayUTC()**

Returns the hours part of the time using the UTC time zone. The number of hours is based on a 24 hour clock.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The hours using the UTC time zone. The number of hours is based on a 24 hour clock.</td>
</tr>
</tbody>
</table>
**Scoped GlideTime - getHourUTC()**

Returns the hours part of the time using the UTC time zone. The number of hours is based on a 12 hour clock. Noon and midnight are represented by 0, not 12.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Number</td>
</tr>
</tbody>
</table>

**Scoped GlideTime - getMinutesLocalTime()**

Returns the number of minutes using the local time zone.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Number</td>
</tr>
</tbody>
</table>

**Scoped GlideTime - getMinutesUTC()**

Returns the number of minutes in the hour based on the UTC time zone.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>Number</td>
</tr>
</tbody>
</table>
## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of minutes in the hour using the UTC time zone.</td>
</tr>
</tbody>
</table>

### Scoped GlideTime - getSeconds()

Returns the number of seconds in the current minute.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of seconds in the minute.</td>
</tr>
</tbody>
</table>

### Scoped GlideTime - getValue()

Gets the time value stored in the database by the GlideTime object in the internal format, HH:mm:ss, and the system time zone.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The time value in the internal format and system time zone.</td>
</tr>
</tbody>
</table>

```javascript
var gt = new GlideTime();
gs.info(gt.getValue()); // Internal Time Zone, UTC
```
**Scoped GlideTime - GlideTime()**

Instantiates a GlideTime object with the current time.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var gt = new GlideTime();
gs.info(gt.getDisplayValue());
```

**Scoped GlideTime - GlideTime(Number milliseconds)**

Instantiates a GlideTime object with its time starting at midnight UTC plus the passed in value.

The value is adjusted for the timezone in which the instance resides. For example, if the user's instance is in a time zone that is -8 hours from the UTC, and 1000 is passed in, the time in the GlideTime object is 16:00:10 (00:00:00 - 8 hours +10 seconds.)

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>milliseconds</td>
<td>Number</td>
<td>Time to add to midnight UTC. Unit: Milliseconds</td>
</tr>
</tbody>
</table>

This example shows adding 10 seconds to midnight (UTC), which is then adjusted for the time zone in which the instance resides. In this case, -8 hours from UTC.

```javascript
var gt = new GlideTime(10000);
gs.info(gt.getDisplayValue());
```

**Output**

```
16:00:10
```

**Scoped GlideTime - setDisplayValue(String asDisplayed)**

Sets a time value using the current user's display format and time zone.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asDisplayed</td>
<td>String</td>
