Gets an encoded query string for the specified field.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>field</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

The following example shows results for a field with an encoded query of `number=INC0001^active=true`.

```javascript
var result = v_query.getCondition("number");
gs.info(result);
```

Output:

```
number=INC0001
```

**v_query - getEncodedQuery()**

Returns the query against a remote table as an encoded query string

For details, see [Encoded query strings](#).

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

The following example is a snippet from [Retrieving specific records from a third-party source](#).
gs.info(v_query.getEncodedQuery());

Output:
active=true^priority=1

**v_query - getParameter(String field)**

Gets the value of a field in an equality query condition.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>field</td>
<td>String</td>
<td>Name of the field to be queried.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Value of the field in the query condition. For example, if name=John is the encoded query, then getParameter(&quot;name&quot;) returns &quot;John&quot;.</td>
</tr>
</tbody>
</table>

The following example is a snippet from *Retrieving specific records from a third-party source*.

v_query.getParameter("caller_id")

Output:
1234512345123451234512345123451234501

**v_query - getSysId()**

Returns the sys_id value in a get query.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Sys_id value in the get query, for example, if sys_id=123, this method returns 123.</td>
</tr>
</tbody>
</table>

The following example is a snippet from Retrieving specific records from a third-party source.

v_query.getSysId();

Output:

a3a7ffb6dba41010db2051735e4619b7

**v_query - getTextSearch()**

Gets a text search query parameter.

See also:
- Encoded query strings
- Querying tables in script

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Text search query parameter, for example email.</td>
</tr>
</tbody>
</table>

In the following example, the method returns true if the query contains a text query parameter, such as GOTO123TEXTQUERY321=email.

// for query value GOTO123TEXTQUERY321=email
v_query.getTextSearch();

Output:

email
**v_query - isGet()**

Determines if the query is a get query, that is, a query that retrieves a record by sys_id.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Boolean  | Flag indicates that query for a specific record has sys_id= as the query format. Valid values:  
|          | • true: Query contains equality query condition on the sys_id field.        |
|          | • false: Query does not include equality query condition on the sys_id field. |

The following example is a snippet from *Retrieving specific records from a third-party source*. If the encoded query is `sys_id=12345123`, the `v_query.isGet()` method returns true. If the encoded query is anything else, such as `Number=INC1234`, the `v_query.isGet()` method returns false.

```java
if (v_query.isGet()) {
    bySysId(v_table, v_query, v_query.getSysId());
} else if (v_query.getParameter("caller_id")) {
    byCallerId(v_table, v_query, v_query.getParameter("caller_id"));
} else {
    fetchAllIncidents(v_table, v_query);
}
```

**v_query - isTextSearch()**

Indicates if the query contains a text query parameter.

See also:
- Encoded query strings
- Querying tables in script

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the query contains a text query parameter.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Query contains a text query parameter.</td>
</tr>
<tr>
<td></td>
<td>• false: Query does not contain a text query parameter.</td>
</tr>
</tbody>
</table>

In the following example, the method returns true if the query contains a text query parameter, such as GOTO123TEXTQUERY321=email.

```java
v_query.isTextSearch();
```

**v_query** - **setLastErrorMessage(String message)**

Sets the last error message in the GlideRecord.

See also **Scoped GlideRecord - getLastErrorMessage()**.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>Error message.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

The following example is a snippet from **Retrieving specific records from a third-party source**.
function fetchAllIncidents(v_table, v_query) {
  // Uses RestMessage with name 'Remote Instance Incidents' and function 'All Incidents'
  // Create a RestMessage first which calls an external REST service
  try {
    var restMessage = new sn_ws.RESTMessageV2('Remote Instance Incidents', 'All Incidents');
    var response = restMessage.execute();
    var responseBody = response.getBody();

    // if REST call ends up in an error, set the last error message which shows up
    // at the bottom of the list view
    if (response.haveError()) {
      v_query.setLastErrorMessage(response.getErrorMessage());
      // can use gs.error() or gs.addErrorMessage() while debugging
      // gs.debug() messages visible in session debugger
      // gs.debug(response.getErrorMessage());
      return;
    }
  } catch (ex) {
    v_query.setLastErrorMessage(ex.message);
    // gs.debug(ex.message);
    return;
  }
}

v_table – Scoped, Global
Scriptable object that enables you to add rows to a remote table.
This API requires the Remote Tables plugin (com.glide.script.vtable) to be activated. Retrieving external data using remote tables and scripts.
Use the v_query scriptable object to query remote tables.

v_table - addRow(Object row)
Adds rows to the remote table.

See also Create a script definition for a remote table.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| row    | Object   | JavaScript object containing field name and value map in which the key is the field name, for example, `{number: "INC0001", sys_id: "a34"}.

Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row.&lt;field value&gt;</td>
<td>String</td>
<td>Represents the value of the selected field. Although no fields are mandatory, ServiceNow recommends sys_id. Example listing only sys_id field and value:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{ sys_id: &quot;&lt;uniqueID&gt;&quot; }</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the row was added to the remote table. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Success.</td>
</tr>
<tr>
<td></td>
<td>• false: Row was not added.</td>
</tr>
</tbody>
</table>

The following example is a snippet from Retrieving specific records from a third-party source.

```javascript
/**
 * Adds rows to `v_table` using `restMessage`
 */
function loadData(v_table, v_query, restMessage) {
    try {
        var response = restMessage.execute();
        var responseBody = response.getBody();

        // if REST call ends up in an error, set the last error message which shows up
        // at the bottom of the list view
        if (response.haveError()) {
            v_query.setLastErrorMessage(response.getErrorMessage());
            // can use gs.error() or gs.addErrorMessage() while debugging
            // gs.debug() messages visible in session debugger
            // gs.debug(response.getErrorMessage());
            return;
        }
    } catch (ex) {
    }
}
v_query.setLastErrorMessage(ex.message);
// gs.debug(ex.message);
return;
}

var transformerDefinition = getTransformerDefinition();
var transformer = new sn_tfrm.Transformer(transformerDefinition, responseBody);
// transformer parses the responseBody and extracts rows
while (transformer.transform()) {
  // row is field-value map e.g. { active:"true", number: "INC00000001"}
  var row = transformer.getRow();
  // you may do any additional transformations to the row like GlideDuration, GlideDataTime etc. For example,
  // row.duration = new GlideDuration(row.duration);

  // finally add the row to the remote table
  v_table.addRow(row);
}

---

**VMUtils - Global**

Provides utility functions for discovery and provisioning of virtual machines.

The `VMUtils` class is available in server-side scripts to convert between UUID and Correlation ID formats.

**VMUtils - turnCorrelationIdToUuid(String correlationId)**

Converts a correlation ID into a UUID for a virtual machine in the ServiceNow system.

---

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>correlationId</td>
<td>String</td>
<td>The correlation ID to convert</td>
</tr>
</tbody>
</table>

---

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The UUID, or an empty string if invalid.</td>
</tr>
</tbody>
</table>
var vmu = new VMUtils();
gs.print(vmu.turnCorrelationIdToUuid('42 10 82 62 35 ca 68-b5 1c 1e f8 5c 0a 0d 5b'));

VMUtils - turnUuidToCorrelationId(String uuid)
Converts a VMware universal unique identifier (UUID) to a format that matches the original format in the ServiceNow system.

vCenter works with UUIDs where the ESXi Linux console worked with this format.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uuid</td>
<td>String</td>
<td>The UUID to convert.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The identifier converted to the ServiceNow format.</td>
</tr>
</tbody>
</table>

var vmu = new VMUtils();
vmu.turnUuidToCorrelationId('13eb78d0-d504-11e1-9b23-0800200c9a66');

WalkWorkflow - Global
Walks the workflow and gets the list of successors for each activity along with a shortest path order that indicates the activity depth in the workflow.

Walkworkflow - computeFullSequences()
Computes the full sequence for every path.

Does not combine paths at Join activities. After calling this method, call getSequences() to yield the computed sequences.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Walkworkflow - computeSequences()**

Computes the sequences of activities.

All sequences leading up to a join end at the join and then a single sequence from the join is computed. This ensures that all sequences can be walked up to a join, and then the sequence can be walked from the join. After calling this method a call to `getSequences()` will yield the computed sequences.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Walkworkflow - dump()**

Outputs the internal state of this class to `gs.print()`.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
**Walkworkflow - dumpSequences()**

Outputs the sequences internal to this class to `gs.print()`.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

**Walkworkflow - dumpShortestPathOrders(description)**

Outputs the shortest path orders internal to this object to `gs.print()`.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

**Walkworkflow - getActivitiesAtOrder(Number order)**

Returns all the activities at the specified shortest path order.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>order</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>An array of activity sys_ids at the specified order. If an empty array is</td>
</tr>
<tr>
<td>Array</td>
<td>returned, there are no more activities.</td>
</tr>
</tbody>
</table>

**Walkworkflow - getSequences()**

Returns the activity sequences.

The `walk()` method must have been called prior to calling this method.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

**Walkworkflow - walk(Boolean fullSequences)**

Walks the workflow and sets up the activity shortest path ordering.

After calling this method the client would call the various accessor methods to obtain relevant data about the workflow.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fullSequences</td>
<td>Boolean</td>
<td>(Optional) If <code>true</code>, computes the full sequences. Default is false.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### Walkworkflow - Walkworkflow(GlideRecord workflowVersion)

Constructor for **Walkworkflow** class.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>workflowVersion</td>
<td>GlideRecord</td>
<td>GlideRecord on table wf_workflow_version of the workflow version to analyze.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Workflow</td>
<td>Workflow object just created.</td>
</tr>
</tbody>
</table>

### WFActivityHandler - Global

The base class for all workflow activities.

As the base class for all workflow activities, this code always executes as part of an activity.

When developing your own workflow activities, create your script object by deriving from this class and overriding methods as necessary to get the functionality you want. Client code must override method `onExecute()` to perform meaningful activity processing.

### WFActivityHandler - debug(String msg, String args)

Logs a debug message.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to send to the log.</td>
</tr>
</tbody>
</table>
Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>args</td>
<td>String</td>
<td>String to send to the log</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

`WFActivityHandler - debug(String msg, Array args)`

Logs a debug message.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to send to the log.</td>
</tr>
<tr>
<td>args</td>
<td>Array</td>
<td>Array of values to send to the log</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

`WFActivityHandler - generate(String activityId, String order, GlideDateTime startAtDspValue, Boolean noCreateFlag)`

Generates approvals and tasks before the activity runs for a preview of upcoming work.

Enables generating objects at the start of a workflow in a pending state. For related information, see Generate workflow activity.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>activityId</td>
<td>String</td>
<td>Sys_id of this running activity. Located in the Workflow Activities [wf_activity] table.</td>
</tr>
</tbody>
</table>
### Parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>order</td>
<td>String</td>
<td>The order number associated with the task or approval.</td>
</tr>
<tr>
<td>startAtDspValue</td>
<td>String</td>
<td>The starting time for the task or approval in GlideDateTime format.</td>
</tr>
<tr>
<td>noCreateFlag</td>
<td>Boolean</td>
<td>Flag that indicates whether to skip creating an approval record.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• true: Do not create an approval record.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• false: Create an approval record.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default: True</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Pre-generation object saved in the workflow scratchpad. For example, the object might be an array of approval IDs. When the activity runs the onExecute function, it can request the pre-generation object to determine one of the following conditions:</td>
</tr>
<tr>
<td></td>
<td>• Approvals have already been created in a pending state.</td>
</tr>
<tr>
<td></td>
<td>• The activity must create the approvals using the onExecute function.</td>
</tr>
</tbody>
</table>

**WFActivityHandler - info(String msg, String args)**

Logs an information message.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to send to the log.</td>
</tr>
<tr>
<td>args</td>
<td>String</td>
<td>String to send to the log.</td>
</tr>
</tbody>
</table>
WFActivityHandler - info(String msg, Array args)

Logs an information message.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to send to the log.</td>
</tr>
<tr>
<td>args</td>
<td>Array</td>
<td>Array of values to send to the log</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

WFActivityHandler - js(String str)

Evaluates activity variables in the script.

Used to evaluate strings that contain el such as `${some script}` or strings starting with `javascript:`. See almost any existing activity for example usage.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>str</td>
<td>String</td>
<td>String that possibly contains embeded el.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The evaluated string.</td>
</tr>
</tbody>
</table>
WFActivityHandler - onCancel()

Event handler for cancel event.

The base class for the activity script sets this activity to be cancelled. Derived classes (activities) can override this method if additional processing is required to cancel this activity. Activity Manual Approvals is an example of overriding this method to perform additional processing to cancel this activity.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

WFActivityHandler - onExecute()

Virtual method. Activity subclasses must override this method to perform work appropriate to the activity.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

WFActivityHandler - runScript(String script)

Enables activities to run a script contained in an activity variable of type script.

Example activities that use this method include If, Wait for condition, and Approval - User.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>script</td>
<td>String</td>
<td>String containing valid Javascript.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>variable</td>
<td>If the script set the workflow variable answer then this value is returned. If not, then the result of the script execution is returned.</td>
</tr>
</tbody>
</table>

#### WFActivityHandler - setActivityOutput()

Sets the activity output property.

See activity [SOAP Message](#).

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

#### WFActivityHandler - setResultFailed(String reason)

Sets the activity result as failed with an optional reason string.

See Activity [SOAP Message](#).

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reason</td>
<td>String</td>
<td>(Optional) Description of the reason this activity failed.</td>
</tr>
</tbody>
</table>
**WFActivityHandler - setResultSucceeded()**
Sets the result of this activity as successful.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**WFActivityHandler - warn(String msg, String args)**
Logs a warning message.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to send to the log.</td>
</tr>
<tr>
<td>args</td>
<td>String</td>
<td>String to send to the log</td>
</tr>
</tbody>
</table>

**WFActivityHandler - warn(String msg, Array args)**
Logs a warning message.
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to send to the log.</td>
</tr>
<tr>
<td>args</td>
<td>Array</td>
<td>Array of values to send to the log</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### WindowsOSNameHelper - Global

Handles the formatting of Windows OS names.

Use in any server-side discovery scripts where you need to format OS names.

#### WindowsOSNameHelper - formatWindowsOSName(String name)

Formats the given Windows OS name.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name to format</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The formatted name</td>
</tr>
</tbody>
</table>

### WindowsOSNameHelper - makeOSChoiceValid(String value)

Ensures that the OS choice is valid.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String</td>
<td>The value to validate</td>
</tr>
</tbody>
</table>
WindowsOSNameHelper - osCleanupName(String name)

Cleans up the specified Windows OS name by stripping out incorrect characters, incorrect capitalization, extra spaces, or trailing spaces.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The name to clean up.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The cleaned up name</td>
</tr>
</tbody>
</table>

Workflow - Global

Workflow scripts provide an interface with the workflow engine. Use these methods to manipulate workflows.

Workflow - broadcastEvent(String contextId, String eventName)

Sends the specified event (message) into the workflow context to pass along to the executing activities.

Typical use of this method is to enable activities that wait for some action to occur before proceeding. For additional information on using broadcastEvent, refer to Workflow event-specific functions.

For a list of the available OOB events, refer to Workflow events in the base system.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contextId</td>
<td>String</td>
<td>The context ID.</td>
</tr>
<tr>
<td>eventName</td>
<td>String</td>
<td>The name of the event.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
//where current is a task record with a workflow context
var wf = new Workflow().getRunningFlows(current);
while(wf.next()) {
    new Workflow().broadcastEvent(wf.sys_id, 'resume');
}
```

**Workflow - cancel(GlideRecord record)**

Cancels all running workflows on this record by broadcasting the `cancel` event to activities in all running workflows on this record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>GlideRecord</td>
<td>GlideRecord on any table. All workflows running on this record will be cancelled.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
//get workflow helper
var workflow = new Workflow();
//cancel all the workflows, where current is a task record with a workflow context
workflow.cancel(current);
```
Workflow - cancelContext(GlideRecord context)

Cancels this running context by broadcasting a cancel event to activities in this workflow context.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>context</td>
<td>GlideRecord</td>
<td>GlideRecord of the running context to cancel.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

// If a workflow has started for this item, cancel it, where current is a task record with a workflow context

```java
if ((current.stage == 'Request Cancelled') && current.context && !current.context.nil()) {
    var w = new Workflow();
    var now_GR = new GlideRecord('wf_context');

    if (now_GR.get(current.context))
        w.cancelContext(now_GR);
}
```

Workflow - deleteWorkflow(GlideRecord current)

Deletes all the workflows on the record.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>current</td>
<td>GlideRecord</td>
<td>GlideRecord for which the caller wants to delete all workflows. This can be any record on any table.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
//where current is a task record with a workflow context
var wkfw = new Workflow();
wkfw.deleteWorkflow(current);
```

**Workflow - fireEvent(GlideRecord eventRecord, String eventName)**

Fires the named event on the input record.

Used in Activities **Approval Coordinator, Timer, Lock**, and some others.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>eventRecord</td>
<td>GlideRecord</td>
<td>The event record.</td>
</tr>
<tr>
<td>eventName</td>
<td>String</td>
<td>The name of the event to send to the executing workflow.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
//where current is a task record with a workflow context
var w = new Workflow();
w.fireEvent(current, 'execute');
```

**Workflow - fireEventById(String eventRecordId, String eventName)**

Fires the named event on the record specified by record ID.

Used in Activities **Approval Coordinator, Timer, Lock**, and some others.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>eventRecordId</td>
<td>String</td>
<td>The sys_id of the glide record.</td>
</tr>
<tr>
<td>eventName</td>
<td>String</td>
<td>The name of the event to send to the executing workflow.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var wkfw = new Workflow();
wkwf.fireEventById('f2400ec10b0a3c1c00ca5bb5c6fae427','Timer');
```

### Workflow - getContexts(GlideRecord record)

Returns all workflow contexts for a specified record.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>GlideRecord</td>
<td>GlideRecord for which the caller wants a list of all workflow contexts. This can be any record on any table for which the caller wants the running workflow contexts.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>GlideRecord in the Workflow context [wf_context] table filtered for all workflow contexts for the specified record (in any state, such as running, cancelled, finished).</td>
</tr>
</tbody>
</table>

```javascript
//where current is a task record with a workflow context
var wkfw = new Workflow();
var context = wkfw.getContexts(current);
while (context.next())
  gs.print(context.started);
```
### Workflow - `getEstimatedDeliveryTime(String workflowId)`

 Gets the estimated time for a workflow to complete.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>workflowId</td>
<td>String</td>
<td>Sys_id of the workflow (table wf_workflow) to get the estimated run time.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Display value from a GlideDuration (e.g., 3 days), or blank if unknown.</td>
</tr>
</tbody>
</table>

```java
var wkfw = new Workflow();
gs.print(wkfw.getEstimatedDeliveryTime('b99a866a4a3623120074c033e005418f'));
```

2 Days

### Workflow - `getEstimatedDeliveryTimeFromWFVersion(GlideRecord wfVersion)`

 Get the estimated elapsed execution time for the workflow version.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>wfVersion</td>
<td>GlideRecord</td>
<td>GlideRecord on table wf_workflow_version of a specific workflow version for which the caller wants the estimated duration of executing.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Display value from a GlideDuration (e.g., 3 days), or blank if unknown.</td>
</tr>
</tbody>
</table>

```java
//where current is a task record with a workflow context
var wkfw = new Workflow();
```
Workflow - `getReturnValue(String workflowID, Number amount, Boolean result)`

Gets the appropriate workflow return value for the input workflow ID. This is either the workflow checked out by the current user or the published workflow with the most recent date.

This is either the workflow checked out by the current user or the published workflow with the most recent date. This method is available starting with the Fuji release.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>workflowID</td>
<td>String</td>
<td>The sys_id of the workflow (table wf_workflow)</td>
</tr>
<tr>
<td>amount</td>
<td>Number</td>
<td>amount</td>
</tr>
<tr>
<td>result</td>
<td>Boolean</td>
<td><code>True</code>, if true</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>???</td>
<td>The return value of the workflow as specified by the Return Value activity. Workflows without a Return Value activity return a null value.</td>
</tr>
</tbody>
</table>

```javascript
var wkfw = new Workflow();
wkfw.getReturnValue('context');
```

**Output:**

```javascript
*** Script: b99a866a4a3623120074c033e005418f
```

Workflow - `getRunningFlows(GlideRecord record)`

Gets all the currently running workflow contexts for the input record.

The input record is any record on any table for which the caller wants the running workflow contexts.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>GlideRecord</td>
<td>GlideRecord of the record for which the caller wants a list of all running workflows.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>GlideRecord on table wf_context and filtered for all executing workflow contexts.</td>
</tr>
</tbody>
</table>

```javascript
//where current is a task record with a workflow context
var wf = new Workflow().getRunningFlows(current);
while(wf.next()) {
    new Workflow().broadcastEvent(wf.sys_id, 'pause');
}
```

**Workflow - getVersion(String workflowID)**

Gets the appropriate workflow version for the input workflow ID. This is either the workflow checked out by the current user or the published workflow with the most recent date.

This is either the workflow checked out by the current user or the published workflow with the most recent date.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>workflowID</td>
<td>String</td>
<td>The sys_id of the workflow (table wf_workflow)</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var wkfw = new Workflow();
wkfw.getVersion('b99a866a4a3623120074c033e005418f');
```
Workflow - `getVersionFromName(String workflowName)`

Returns the appropriate workflow version for the input workflow name.

See `getVersion()` for more information.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>workflowName</td>
<td>String</td>
<td>Name of the workflow (table wf_workflow)</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var wkfw = new Workflow();
wkfw.getVersionFromName('Emergency Change');
```

Workflow - `getWorkflowFromName(String workflowName)`

Returns the sys_id of the workflow associated with the specified workflow name.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>workflowName</td>
<td>String</td>
<td>Name of the workflow.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The sys_id of the workflow associated with the passed in name.</td>
</tr>
</tbody>
</table>

```javascript
var wflw = new Workflow();
gs.print(wflw.getWorkflowFromName('Emergency Change'));
```

Workflow - `hasWorkflow(GlideRecord record)`

Determines if a specified record has any workflow contexts associated to it.

This includes running and completed workflow contexts.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>GlideRecord</td>
<td>GlideRecord under scrutiny. This GlideRecord can be from any table.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True, if record has associated workflow; otherwise, returns False.</td>
</tr>
</tbody>
</table>

```javascript
var wkfw = new Workflow();
gs.print(wkfw.hasWorkflow('f2400ec10b0a3c1c00ca5bb5c6fae427'));
```

false

Workflow - `restartWorkflow(GlideRecord current, Boolean maintainStateFlag)`

Recalculates the approvals and tasks for a workflow by adding new approvals and tasks, while not resetting current approvals and tasks.

You can use this method to perform such tasks as adding a company to a change request, without resetting the current approvals for companies already in the workflow.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>current</td>
<td>GlideRecord</td>
<td>GlideRecord of the record this workflow is executing. This can by any record on any table.</td>
</tr>
</tbody>
</table>
| maintainStateFlag | Boolean | Flag that indicates whether to maintain all approvals and tasks in their current state. Valid values:  
  - true: Maintain all approvals and tasks in their current state.  
  - false: Update all approval and task states. |
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

This example shows the workflow being restarted with the approval file changing from Rejected to Requested.

```javascript
(function(){
    var comment = 'Workflow Restarted - the Approval Field changing from Rejected to Requested';
    var gLock = new GlideRecordLock(current);
    gLock.setSpinWait(50);
    if (gLock.get()) {
        new Workflow().restartWorkflow(current, false);
        current.setDisplayValue('approval_history', comment);
    }
})
```

**Workflow - runFlows(GlideRecord record, String operation)**

Runs all workflows for a given record in a given table and its descendant tables.

Sample usage can be seen in the Script Includes "SNC - Run parent workflows", and "SNC - Run parent workflows (Approval)".

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>GlideRecord</td>
<td>GlideRecord to run workflows against.</td>
</tr>
<tr>
<td>operation</td>
<td>String</td>
<td>Database operation. Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• insert</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• update</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• delete</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
```javascript
var now_GR = new GlideRecord('wf_test');
now_GR.addQuery('parent', current.parent);
now_GR.addQuery('sys_id','!=',current.sys_id);
now_GR.query();
while(now_GR.next()) {
    new Workflow().runFlows(now_GR, 'update');
}
```

**Workflow - startFlow(String workflowId, GlideRecord current, String operation, Array vars)**

Starts a specified workflow.

See script include WorkflowScheduler and Business Rule "Start Workflow" on table sc_req_item for examples of use.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>workflowId</td>
<td>String</td>
<td>The sys_id of the workflow to start. This sys_id refers to table wf_workflow.</td>
</tr>
<tr>
<td>current</td>
<td>GlideRecord</td>
<td>The record to use as current in this workflow. This is normally from the Table field of the workflow properties for this workflow.</td>
</tr>
<tr>
<td>operation</td>
<td>String</td>
<td>The operation to perform on current. Possible values: insert, update, delete.</td>
</tr>
<tr>
<td>vars</td>
<td>Array</td>
<td>Collection of variables to add to the workflow</td>
</tr>
</tbody>
</table>

```javascript
///where current is a task record with a workflow context
var w = new Workflow();
var context = w.startFlow(id, current, current.operation(), getVars());
```

**Workflow - startFlowFromContextInsert(GlideRecord context, String operation)**

Helper method for business rule Auto start on context.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>context</td>
<td>GlideRecord</td>
<td>GlideRecord on table wf_context of a new record (the &quot;current&quot; record in the business rule).</td>
</tr>
<tr>
<td>operation</td>
<td>String</td>
<td>Database operation being performed. One of insert, update, delete.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
//where current is a task record with a workflow context
   current.name = current.workflow_version.name;
   current.started_by.setValue(gs.userID());

   if (gs.nil(current.id)) {
      var now_GR = new GlideRecord('wf_workflow_execution');
      now_GR.name = current.name;
      now_GR.insert();

      current.table = 'wf_workflow_execution';
      current.id = now_GR.sys_id;
   }

   var wf = new Workflow();
   wf.startFlowFromContextInsert(current, current.operation())
```

**Workflow - startFlowRetroactive(String workflowId, Number retroactiveMSecs, GlideRecord current, String operation, Array, ???)**

Used by business rule **Start Workflow** on table task_sla. This starts a workflow and the extra arguments to this method are used by activity "Timer" to pause the execution of the workflow for some duration.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>workflowID</td>
<td>String</td>
<td>The sys_id of the workflow to start. This sys_id refers to table wf_workflow.</td>
</tr>
<tr>
<td>retroactiveMSeconds</td>
<td>Number</td>
<td>Delay in milliseconds used by Activity Timer.</td>
</tr>
<tr>
<td>current</td>
<td>GlideRecord</td>
<td>GlideRecord of the record to use as current in this workflow. This is normally from the Table field of the workflow properties for this workflow</td>
</tr>
<tr>
<td>operation</td>
<td>String</td>
<td>Database operation being performed. One of insert, update, delete.</td>
</tr>
<tr>
<td>vars</td>
<td>Array</td>
<td>Collection of variables to add to the workflow.</td>
</tr>
<tr>
<td>withSchedule</td>
<td>???</td>
<td>Schedule used by Activity Timer.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>A GlideRecord on table wf_context on the inserted record for this newly created workflow context.</td>
</tr>
</tbody>
</table>

// is this a retroactive start?

```javascript
// where current is a task record with a workflow context
var msecs = new GlideDateTime().getNumericValue() -
current.start_time.glideObject().getNumericValue();

// treat this as a retroactive workflow start if the SLA started more than 5 seconds ago
var w = new Workflow();
if (msecs <= 5000)
    w.startFlow(id, current, current.operation());
else
    w.startFlowRetroactive(id, msecs, current, current.operation());

// update the record in case the workflow changed some values
current.update();
```
**Workflow - Workflow()**

Constructor for `Workflow` class.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
var w = new Workflow();
```

**Workflow - Scoped**

The scoped Workflow API provides methods that can be used in an activity definition script.

There are no constructors for creating an instance of a scoped workflow object. Instead, use the global `workflow` object available in activity scripts. This workflow object is available in any script location inside a workflow.

**Scoped Workflow - debug(String message, Object args)**

Adds a debug message to the log.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>The message to add to the log.</td>
</tr>
<tr>
<td>args</td>
<td>Object</td>
<td>Arguments to add to the message.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The message added to the log.</td>
</tr>
</tbody>
</table>
var loggedMessage = workflow.debug("All is well");

**Scoped Workflow - error(String message, Object args)**

Adds an error message to the log.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>The message to add to the log.</td>
</tr>
<tr>
<td>args</td>
<td>Object</td>
<td>Arguments to add to the message.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The logged message</td>
</tr>
</tbody>
</table>

var loggedMessage = workflow.error("An error has occurred. ");

**Scoped Workflow - getVariable(String name)**

Returns the specified variable's value.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The variable name</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The variable's value</td>
</tr>
</tbody>
</table>

var value = workflow.getVariable("task");

**Scoped Workflow - info(String message, Object args)**

Adds an informational message to the log.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>The message to add to the log.</td>
</tr>
<tr>
<td>args</td>
<td>Object</td>
<td>Arguments to add to the message.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The message that is logged.</td>
</tr>
</tbody>
</table>

```javascript
var loggedMessage = workflow.info("All is well");
```

## Scoped Workflow - inputs

Object that contains the workflow variables.

This is not a method, but rather a way to reference the variables in a workflow object, such as the user. Workflow variables are defined in the properties of the workflow or by scripted activities.

<table>
<thead>
<tr>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>inputs</td>
</tr>
</tbody>
</table>

```javascript
var user = workflow.inputs.u_user;
```

## Scoped Workflow - name()

Returns the workflow name.

## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The workflow name</td>
</tr>
</tbody>
</table>

```javascript
var name = workflow.name();
```

**Scoped Workflow - removeVariable(String name)**

Removes the specified variable from the workflow.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The variable name</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var value = workflow.removeVariable("task");
```

**Scoped Workflow - result**

Element of the workflow object that contains the workflow results.

This is not a method, but rather the element in the workflow object that contains the results of a workflow.

**Field**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>String</td>
<td>Workflow results.</td>
</tr>
</tbody>
</table>

```javascript
var wfResult = workflow.result;
```
Scoped Workflow - scratchpad()

Returns the workflow's scratchpad object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The scratchpad object.</td>
</tr>
</tbody>
</table>

```javascript
var scratchpad = workflow.scratchpad();
```

Scoped Workflow - setResult(String result)

Sets the workflow's result.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>String</td>
<td>The workflow's result</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
workflow.setResult("Success");
```

Scoped Workflow - setVariable(String name, Object value)

Sets the specified variable to the specified value.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>The variable name</td>
</tr>
<tr>
<td>value</td>
<td>Object</td>
<td>The value to be assigned to the variable.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```java
workflow.setVariable("task", "terrible");
```

### Scoped Workflow - `warn(String message, Object args)`

Adds a warning message to the log.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>String</td>
<td>The message to add to the log.</td>
</tr>
<tr>
<td>args</td>
<td>Object</td>
<td>Arguments to add to the message.</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>

<td>String</td>
<td>The logged message</td>
</tr>
</tbody>
</table>

```java
var loggedMessage = workflow.warn("Check your permissions.");
```

### WorkflowDuration - Global

This class calculates the duration (in seconds) based on the variables of a workflow activity. It is an interface between `Workflow Timer()` and `DurationCalculator()`.
WorkflowDuration - addSeconds(GlideRecord record, Number amount)

Adds the number of seconds to the specified start date/time.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>GlideRecord</td>
<td>description</td>
</tr>
<tr>
<td>amount</td>
<td>Number</td>
<td>amount</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True, if object was successfully created.</td>
</tr>
</tbody>
</table>

WorkflowDuration - calculate(GlideRecord record)

Calculates the number of seconds and the due date.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>GlideRecord</td>
<td>The record that contains the fields with the schedule, timezone, and date/time information. This is almost always activity.vars.<strong>var_record</strong>.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

WorkflowDuration - calculateTimeLeft(GlideRecord record)

Calculates the number of seconds remaining to the specified end date/time.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record</td>
<td>GlideRecord</td>
<td>The record that contains the fields with the schedule, timezone, and date/time information. This is almost always <code>activity.vars.__var_record__</code>.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**WorkflowDuration - getEndDateTime()**

Returns the end date/time set by a call to `calculate(record)`.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideDateTime</td>
<td>The end date/time.</td>
</tr>
</tbody>
</table>

**WorkflowDuration - getSeconds()**

Returns the seconds value that was set by a call to `calculate(record)`.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The number of seconds set by a call to calculate(record).</td>
</tr>
</tbody>
</table>

**WorkflowDuration - getTotalSeconds()**

Returns the totalSeconds value that was set by a call to calculate(record).

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number</td>
<td>The total number of seconds set by a call to calculate(record).</td>
</tr>
</tbody>
</table>

**WorkflowDuration - setEndDateTime(String dt)**

Sets the end date/time to use when calculating the remaining time.

To convert the value into the GlideDateTime internal format, use GlideDateTime.getValue().

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dt</td>
<td>String</td>
<td>The end date/time to use.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**WorkflowDuration - setEndDateTime(GlideDateTime dt)**

Sets the end date/time to use when calculating the remaining time.
To convert the value into the GlideDateTime internal format, use `GlideDateTime.getValue()`.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dt</td>
<td>GlideDateTime</td>
<td>The end date/time to use.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**WorkflowDuration - setStartDateTime(String dt)**

Sets the start date/time to use in the calculations.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dt</td>
<td>String</td>
<td>The start date/time to use, in GMT.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**WorkflowDuration - setStartDateTime(GlideDateTime dt)**

Sets the start date/time to use in the calculations.

To convert the value into the GlideDateTime internal format, use `GlideDateTime.getValue()`.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dt</td>
<td>GlideDateTime</td>
<td>The start date/time to use.</td>
</tr>
</tbody>
</table>
WorkflowDuration - setUsedSecs(Number secs)

Sets the used seconds compensation, where the number of seconds is the number of seconds inside of any schedule.

Can be a -ve number, which extends the duration.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>secs</td>
<td>Number</td>
<td>The number of used seconds to set.</td>
</tr>
</tbody>
</table>

WorkflowDuration - setWorkflow(Object schedule, Object timezone)

Sets the workflow schedule/timezone. Used for schedule_type workflow_schedule and timezone_type workflow_timezone).

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule</td>
<td>Object</td>
<td>The schedule to use. Usually from the workflow context.schedule.</td>
</tr>
<tr>
<td>timezone</td>
<td>Object</td>
<td>The timezone to use. Usually from the workflow context.timezone.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
WorkflowModelManager - Global

The WorkflowModelManager class provides a way to query the workflow model, to step backwards and forwards between specified *wf_history* items, and to query the history for activity and transition-specific information.

The interaction with the WorkflowModelManager class is through the ActivityHistoryRecord data object. The ActivityHistoryRecord is an inner class and is only used while interacting with WorkflowModelManager.

To acquire the executed history of the workflow activities:

```javascript
var model = new WorkflowModelManager('myContextId');
var activities = model.getExecutedHistory();
```

To output the playback of the workflow:

```javascript
var model = new WorkflowModelManager('myContextId');
model.getExecutedHistory();
model.playBack();
```

At this time, the playback is required to load the executed transitions. This will also play a role in walking backwards on a model to rollback to a specific activity.

To see the details of the cached model:

```javascript
var model = new WorkflowModelManager('myContextId');
model.getExecutedHistory();
model.dump();
```

Related information

**WFActivityHandler - Global**

**WorkflowModelManager - getActivityHistoryRecordById(String haRecordSysId)**

Retrieves the history activity that is cached by the *wf_history.sys_id* provided in the argument.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>haRecordSysId</td>
<td>String</td>
<td>The sys_id of the activity history (table wf_history).</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActivityHistoryRecord</td>
<td>The ActivityHistoryRecord JavaScript object requested.</td>
</tr>
</tbody>
</table>

**WorkflowModelManager - getAllTransitionedIntoActivity(Object description)**

Retrieves the history activities that executed and transitioned into the one represented by the `sys_id` in the argument.

The `next` status is based on the `wf_activity.sys_id` associated with the activity represented in the haRecord existing as a TO in a transition associated with any ActivityHistoryRecords that executed in the workflow's history. (This differs from `getPreviousByTransition`, which only returns TO transitions that come before the haRecord in the execution sequence (by time).) The return value is a collection of ActivityHistoryRecords that identify the argument haRecord.wfaId as their TO activity. The return values are based on all transitions in the executed history collection that transition To get the activity that executed prior to this activity in time use `getPreviousByExecutedOrder`.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>Object</td>
<td>ActivityHistoryRecord JavaScript object.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Array</td>
<td>Array of ActivityHistoryRecord JavaScript objects.</td>
</tr>
</tbody>
</table>

**WorkflowModelManager - getAllTransitionedIntoActivityId(String haRecordSysId)**

Retrieves the history activities that executed and transitioned into the one represented by the `sys_id` in the argument. The `next` status is based on the `wf_activity.sys_id` associated with the activity represented in the haRecord existing as a TO in a transition associated with any ActivityHistoryRecords that executed in the workflow's history. (This differs from `getPreviousByTransition`, which returns only TO transitions that come before the haRecord in the execution sequence (by time).) The return value is a collection of ActivityHistoryRecords that identify the argument haRecord.wfaId as their TO activity.
The next status is based on the `wf_activity.sys_id` associated with the activity represented in the `haRecord` existing as a TO in a transition associated with any `ActivityHistoryRecords` that executed in the workflow's history. (This differs from `getPreviousByTransition`, which returns only TO transitions that come before the `haRecord` in the execution sequence (by time).) The return value is a collection of `ActivityHistoryRecords` that identify the argument `haRecord.wfaId` as their TO activity.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>haRecordSysId</code></td>
<td>String</td>
<td>The sys_id of the activity history (table <code>wf_history</code>).</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Array</td>
<td>Array of <code>ActivityHistoryRecord</code> JavaScript objects requested.</td>
</tr>
</tbody>
</table>

```javascript
var model = new WorkflowModelManager('a143585c3b001000dada82c09ccf3d44');
    model.getExecutedHistory();
    var activity = model.begin;
    gs.print('activity: ' + activity.wfaName + ', transitions: ' +
               activity.transitions.length);
    while( activity != null){
        gs.print('activity: ' + activity.wfaName + ', transitions: ' +
               activity.transitions.length);
        var parents = model.getAllTransitionedIntoActivity(activity);
        for( var i = 0; i < parents.length; i++ ){
            gs.print('-------------- parent activity: ' + parents[i].wfaName);
        }
        activity = model.getNextByExecutedOrder( activity );
    }
```

**WorkflowModelManager - getExecutedHistory()**

This is the worker method that must be called to initialize the `WorkflowModelManager` object. In the process of initializing the `WorkflowModelManager` object, `getExecutedHistory()` creates and populates the `activityHistoryRecord` data object array (which is a member of the `WorkflowModelManager` class). Most `WorkflowModelManager` methods return a subset
of the `activityHistoryRecord` array. Your script can then call one or more of the `activityHistoryRecord` methods to accomplish further work.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String Array</td>
<td>An ordered array of sys_ids from table wf_history. It is unlikely client code would use the return value; it is kept internally to this object for use by subsequent method calls.</td>
</tr>
</tbody>
</table>

```javascript
var model = new WorkflowModelManager('myContextId');
var activities = model.getExecutedHistory();
var current = model.getActivityHistoryRecordById('d6681d573b130000dada82c09ccf3d10');
```

**WorkflowModelManager - getFinalExecutedActivityList()**

Queries the wf_history table by context and retrieves all the activities executed in the workflow given by the context set in the construction of this object.

This function produces a list of executed activities in the exact order each activity passed through the server side ActivityManager.java using the new activity_index to force the order coming out of the database. On its this call will not give the full picture; it needs to load and map the transitions.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Array</td>
<td>Array of ActivityHistoryRecord javascript objects.</td>
</tr>
</tbody>
</table>
WorkflowModelManager - getFinalExecutedActivityIdList()

Gets the list of `wf_history.sys_ids` of all activities that successfully executed and were not rolled back or skipped up to the moment the function was called.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String Array</td>
<td>Array of <code>wf_history.sys_id</code> values for executed activities.</td>
</tr>
</tbody>
</table>

```javascript
var model = new WorkflowModelManager('ee3e0a053b101000dada82c09ccf3d7c');
model.getExecutedHistory();
var finals = model.getFinalExecutedActivityIdList();
gs.print(' EXECUTION PATH IDs --------------- : ' + finals.length);

for ( var x = 0; x < finals.length; x++ ) {
    gs.print(finals[x] );
}
```

WorkflowModelManager - getNextByExecutedOrder(Object haRecord)

Retrieves the history activity that executed just after to the one provided in the argument.

The `next` status is based on the activity index reflecting the nearest prior activity in time and not necessarily the nearest next `wf_activity` the provided activity transitioned to. To get the nearest next activity that transitioned to this `haRecord` passed in, use `getNextByTransitionOrder(haRecord)`.

⚠️ **Note:** In the process of assembling the execution order array, blanks are left in the array where history objects have been deleted. This is done to ensure the index in the array and the activity_index of the object remain in sync. For that reason, all objects coming out of the execution order array should be tested for `nil()` and not assumed to be the previous record based on activity_index or array index value alone.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>haRecord</td>
<td>Object</td>
<td>ActivityHistoryRecord JavaScript object.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The ActivityHistoryRecord JavaScript object requested.</td>
</tr>
</tbody>
</table>

**WorkflowModelManager - getNextByExecutedOrderId(String haRecordSysId)**

Retrieves the history activity that is cached by the `wf_history.sys_id` provided in the argument and then calls into `getNextByExecutedOrder()` with the retrieved JavaScript object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>haRecordSysId</td>
<td>String</td>
<td>The sys_id of the activity history (table wf_history).</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The ActivityHistoryRecord JavaScript object requested.</td>
</tr>
</tbody>
</table>

```javascript
var model = new WorkflowModelManager('7b3e01573b130000dada82c09ccf3dcf');
    model.getExecutedHistory();
    var current = model.getActivityHistoryRecordById('d6681d573b130000dada82c09ccf3d10');
    current.debugDump();

    var results = model.getNextByExecutedOrderId(current.sys_id);
    results.debugDump();
```

**WorkflowModelManager - getNextByTransitionId(String haRecordSysId)**

Retrieves the history activity that executed just after to the one identified by the `sys_id` provided in the argument. This function retrieves the cached history record associated with the provided `wf_history.sys_id` and then calls...
getNextByTransition. The return values are based on which transitions came before the haRecord submitted and not necessarily the activities that executed just prior to the haRecord in time. To get the activity that executed prior to this activity in time, use getNextByExecutedOrder.

This function retrieves the cached history record associated with the provided wf_history.sys_id and then calls getNextByTransition. The return values are based on which transitions came before the haRecord submitted and not necessarily the activities that executed just prior to the haRecord in time. To get the activity that executed prior to this activity in time, use getNextByExecutedOrder.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>haRecordSysId</td>
<td>String</td>
<td>sys_id of the activity history (table wf_history).</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Array</td>
<td>Array of ActivityHistoryRecord JavaScript objects.</td>
</tr>
</tbody>
</table>

```javascript
var model = new WorkflowModelManager('7b3e01573b130000dada82c09ccf3dcf');
    model.getExecutedHistory();
    model.playBack();

    var current = model.getActivityHistoryRecordById('d6681d573b130000dada82c09ccf3d10');
    current.debugDump();
    var results = model.getNextByTransitionId(current.sys_id);
    gs.print('COMPLETED NEXT' + results.length);
    for( var i = 0; i < results.length; i++){
        results[i].debugDump();
    }
```

WorkflowModelManager - getPreviousByExecutedOrder(Object haRecord)

Retrieves the history activity that executed just previous to the one provided in the argument.

The previous status is based on the activity index reflecting the nearest prior activity in time and not necessarily the nearest prior activity with a valid transition.
to this activity. To get the nearest prior activity that transitioned to this haRecord passed in use `getPreviousByTransition(haRecord)`.

<i>Note:</i> In the process of assembling the execution order array, blanks are left in the array where history objects have been deleted. This ensures that the index in the array and the activity_index of the object remain in sync. For that reason, all objects coming out of the execution order array should be tested for `nil()` and not assumed to be the previous record based on activity_index or array index value.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>haRecord</td>
<td>Object</td>
<td>ActivityHistoryRecord JavaScript object</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>The ActivityHistoryRecord JavaScript object requested.</td>
</tr>
</tbody>
</table>

**WorkflowModelManager - getPreviousByExecutedOrderId(String haRecordSysId)**

Retrieves the history activity cached by the `wf_history.sys_id` provided in the argument, then calls `getPreviousByExecutedOrder()` with the retrieved JavaScript object.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>haRecordSysId</td>
<td>String</td>
<td>Workflow history system ID (wf_history.sys_id)</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActivityHistoryRecord</td>
<td>The ActivityHistoryRecord JavaScript object requested.</td>
</tr>
</tbody>
</table>

```javascript
var model = new WorkflowModelManager('contextId');
model.getExecutedHistory();
var current = model.getActivityHistoryRecordBySysId('wf_history.sys_id');
```
WorkflowModelManager - getPreviousByTransition(Object haRecord)

Retrieves the history activities that executed just prior to the one provided in the argument.

The **next** status is based on the `wf_activity.sys_id` associated with the activity represented in the `haRecord` existing as a TO in a transition associated with any ActivityHistoryRecords that come before the `haRecord` in the execution sequence. (This differs from `getAllTransitionedIntoActivity`, which returns all TO transitions up to the given `haRecord` in the execution sequence.) The return value is a collection of ActivityHistoryRecords that identify the argument `haRecord.wfaId` as their TO activity. The return values are based on which transitions came before the `haRecord` submitted and not necessarily the activities that executed just prior to the `haRecord` in time. To get the activity that executed prior to this activity in time, use `getPreviousByExecutedOrderId`.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>haRecord</td>
<td>Object</td>
<td>ActivityHistoryRecord JavaScript object.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Array</td>
<td>Array of ActivityHistoryRecord JavaScript objects requested.</td>
</tr>
</tbody>
</table>

WorkflowModelManager - getPreviousByTransitionId(String haRecordSysId)

Retrieves the history activities that executed just prior to the one provided in the argument.

The **next** status is based on the `wf_activity.sys_id` associated with the activity represented in the `haRecord` existing as a TO in a transition associated with any ActivityHistoryRecords that come before the `haRecord` in the execution sequence. The return value is a collection of ActivityHistoryRecords that identify the argument `haRecord.wfaId` as their TO activity. The return values are based on which transitions came before the `haRecord` submitted and not necessarily the activities that executed just prior to the `haRecord` in time. To get the activity that executed prior to this activity in time, use `getPreviousByExecutedOrderId`. 

```javascript
current.debugDump();

var results = model.getPreviousByExecutedOrderId(current.sys_id);
results.debugDump();
```
not necessarily the activities that executed just prior to the haRecord in time. To get the activity that executed prior to this activity in time use getPreviousByExecutedOrder.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>haRecordSysId</td>
<td>String</td>
<td>The sys_id of the activity history (table wf_history).</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Array of ActivityHistoryRecord JavaScript objects requested.</td>
</tr>
</tbody>
</table>

**WorkflowModelManager - WorkflowModelManager(String contextId)**

Creates a new WorkflowModelManager object (constructor) within the specified context.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>contextId</td>
<td>String</td>
<td>The ID for the context in which you want the WorkflowModelManager created.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ActivityHistoryRecord</td>
<td>The ActivityHistoryRecord JavaScript object requested.</td>
</tr>
</tbody>
</table>

var model = new WorkflowModelManager('MyContextId');

**WorkflowModelManagerAjax - Global**

Provides an AjaxProcessor wrapper for the WorkflowModelManager. This class derives from AbstractAjaxProcessor.

Use this class in the Workflow Debug context menus.
WorkflowModelManagerAjax - getExecutedHistory()

Puts the execution history into the return parameter based on the query string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

WorkflowModelManagerAjax - getFinalExecutedActivityIdList()

Puts the final execution activity list into the return parameter based on the query string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

WorkflowModelManagerAjax - getRolledBackActivityIdList()

Puts the rollback activity list into the return parameter based on the query string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
<tr>
<td>Returns</td>
<td></td>
</tr>
<tr>
<td>---</td>
<td></td>
</tr>
<tr>
<td><strong>Type</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**WorkflowScheduler - Global**

This code is executed in business rule *Set workflow scheduler script* on table *wf_workflow_schedule*.

**WorkflowScheduler - run()**

Starts the workflow specified in current, which is a record in table *wf_workflow_schedule*.

This method is called from the Business Rule Set *workflow scheduler script* on table *wf_workflow_schedule*.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>void</td>
</tr>
</tbody>
</table>

**WorkflowTimeline - Global**

Generates a view that shows a workflow context on the timeline.

**WorkflowTimeline-getitems()**

Generates the Ajax response for the timeline.

This method is called by the Prototype JavaScript Framework. See the *AbstractTimelineSchedulePage* script include for more details.
<table>

**XMLDocument2 - Scoped**

XMLDocument2 is a JavaScript Object wrapper for parsing and extracting XML data from an XML string.

Use this JavaScript class to create an object from an XML string, usually a return value from a web-service invocation, or the XML payload of ECC Queue. Using the XMLDocument2 object in a JavaScript business rule lets you query values from the XML elements and attributes directly.

An XML string has a tree structure, and the parts of the structure are called nodes. An XMLDocument2 object deals with two node types, element, and document element. An element node is a node with a name and possibly attributes and child nodes. A document-element node is the root node of the XML tree. It is the only node without a parent node.

**Scoped XMLDocument2 - createElement(String name)**

Creates and adds an element node to the current node. The element name is the string passed in as a parameter. The new element has no text child nodes.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
<td>The new element's name.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>XMLNode</td>
<td>Current XML node.</td>
<td></td>
</tr>
</tbody>
</table>
```javascript
var xmlString = "<test>
  <one>
    <two att="xxx">abcd1234</two>
    <three boo="yah" att="yyy">1234abcd</three>
    <two>another</two>
  </one>
  <number>1234</number>
";

var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
xmlDoc.createElement("new2");

gs.info(xmlDoc);
```

**Output:**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<test>
  <one>
    <two att="xxx">abcd1234</two>
    <three att="yyy" boo="yah">1234abcd</three>
    <two>another</two>
  </one>
  <number>1234</number>
  <new2></new2>
</test>
```

**Scoped XMLDocument2 - createElementWithTextValue(String name, String value)**

Creates and adds an element node with a text child node to the current node.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the element to add.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Element's text value.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLNode</td>
<td>Current XML node.</td>
</tr>
</tbody>
</table>
var xmlString = "<test>" +
  "  <one>" +
  "    <two att="xxx">abcd1234</two>" +
  "    <three boo="yah" att="yyy">1234abcd</three>" +
  "    <two>another</two>" +
  "  </one>" +
  "  <number>1234</number>" +
"</test>";

var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
xmlDoc.createElementWithTextValue("new", "test");
gs.info(xmlDoc);

Output:

<?xml version="1.0" encoding="UTF-8"?><test>
  <one>
    <two att="xxx">abcd1234</two>
    <three att="yyy" boo="yah">1234abcd</three>
    <two>another</two>
  </one>
  <number>1234</number>
  <new>test</new>
</test>

Scoped XMLDocument2 - getDocumentElement()

Gets the document element node of the XMLdocument2 object. The document element node is the root node.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLNode</td>
<td>The document element.</td>
</tr>
</tbody>
</table>

var xmlString = "<test>" +
  "  <one>" +
"    <two att="xxx">abcd1234</two>" +
"    <three boo="yah" att="yyy">1234abcd</three>" +
"    <two>another</two>" +
"    </one>" +
"    <number>1234</number>" +
"    </test>";

var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
//returns the root node of the document tree.
var rootNode = xmlDoc.getDocumentElement();
gs.info(rootNode.getTextContent());

Output:

abcd1234    1234abcd    another    1234

Scoped XMLDocument2 - getFirstNode(String xPath)
Gets the first node in the specified xPath.

This method only supports a subset of predicate xPath expressions. For example, assume the following document:

<store>
  <resources company="ABC Inc">
    <resources type="servers" />
  </resources>
  <resources company="XYZ Inc">
    <resource type="bookstore">
      <book>
        <title>Windows</title>
        <price>10</price>
      </book>
      <book year="2009">
        <title>Harry Potter</title>
        <price>50</price>
      </book>
      <book year="1999">
        <title>Learning XML</title>
        <price>120</price>
      </book>
      <book year="2019">
        <title>Learning Java</title>
        <price>99</price>
      </book>
    </resource>
  </resources>
</store>
This method supports the following xPath expressions with predicates:

```
"/store/resources/resource[@type='bookstore']/book[@year='1999'"]
"/store/resources/resource[@type='bookstore']/book[@year]
"/store/resources/resource[@type='bookstore']/book[price > 100]
```

However, it does not support the following xPath expressions with predicates:

```
"/store/resources/resource[@type='bookstore']/book[2]
"/store/resources/resource[@type='bookstore']/book[last()]
"/store/resources/resource[@type='bookstore']/book[position()>2]
```

To work around this, use xPath without predicates, such as 
`"/store/resources/resource[@type='bookstore']/book"` and then filter the nodes in the script using the `getFirstNode()` and `getNextNode()` methods.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xPath</td>
<td>String</td>
<td>The xPath to obtain the node from.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLNode</td>
<td>The first node.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>
  <one>
    <two att="xxx">abcd1234</two>
    <three boo="yah" att="yyy">1234abcd</three>
    <two>another</two>
  </one>
  <number>1234</number>
</test>";
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
var foo = xmlDoc.getFirstNode('/test/one/two');
gs.info(foo.getTextContent());
```
Scoped XMLDocument2 - getNextNode(Object current)

Gets the node after the specified node.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>current</td>
<td>Object</td>
<td>The current node.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLNode</td>
<td>The next node.</td>
</tr>
</tbody>
</table>

```java
var xmlString = "<test>" +
    "  <one>" +
    "    <two att="xxx">abcd1234</two>" +
    "    <three boo="yah" att="yyy">1234abcd</three>" +
    "    <two>another</two>" +
    "  </one>" +
    "  <number>1234</number>" +
"</test>";
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
var foo = xmlDoc.getFirstNode('/test/one/two');
var foo2 = xmlDoc.getNextNode(foo);
gs.info(foo.getTextContent());
gs.info(foo2.getTextContent());
```

Output:

```
abcd1234
another
```

Scoped XMLDocument2 - getNode(String xPath)

Gets the node specified in the xPath.
Note: This method is intended for use with small documents since it parses the entire document to match the XPath expression. If the document is too large, an out of memory error may occur. For large documents, use the `getFirstNode(String xpath)` and `getNextNode(Object current)` methods, which are designed to stream through the document without parsing the entire document.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xpath</td>
<td>string</td>
<td>XPath of the node to obtain.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLNode</td>
<td>Current XML node.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>
  <one>
    <two att="xxx">abcd1234</two>
    <three boo="yah" att="yyy">1234abcd</three>
    <two>another</two>
  </one>
  <number>1234</number>
</test>";
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
var node = xmlDoc.getNode("/test/one/two");
gs.info(node);
```

Output:

```
<two att="xxx">abcd1234</two>
```

Scoped XMLDocument2 - getNodeText(String xpath)

Gets all the text child nodes from the node referenced in the specified XPath.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xpath</td>
<td>string</td>
<td>XPath of the text to obtain.</td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Text children in the XPath.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>" +
    "  <one>" +
    "    <two att="xxx">abcd1234</two>" +
    "    <three boo="yah" att="yyy">1234abcd</three>" +
    "    <two>another</two>" +
    "  </one>" +
    "  <number>1234</number>" +
"</test>";
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
gs.info(xmlDoc.getNodeText("//two"));
```

Output: abcd1234

**Scoped XMLDocument2 - parseXML(String xmlDoc)**

Parses the XML string and loads it into the XMLDocument2 object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlDoc</td>
<td>String</td>
<td>The document to parse.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>Flag that indicates whether the content was parsed.</td>
</tr>
</tbody>
</table>

This example parses the xmlString and loads it into the xmlDocument2 object.
Scoped XMLDocument2 - setCurrentElement(XMLNode element)

Makes the node passed in as a parameter the current node.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>element</td>
<td>XMLNode</td>
<td>The element node to set as the current node.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>" +
   "  <one>" +
   "    <two att="xxx">abcd1234</two>" +
   "    <three boo="yah" att="yyy">1234abcd</three>" +
   "    <two>another</two>" +
   "  </one>" +
   "  <number>1234</number>" +
"</test>";
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
//returns the root node of the document tree.
var rootNode = xmlDoc.getDocumentElement(); //returns org.w3c.dom.Element
// sets the root node as the current element
xmlDoc.setCurrentElement(rootNode);
```

Scoped XMLDocument2 - setNamespaceAware(Boolean aware)

When set to true, the XMLDocument2 object processes the document with XML namespaces.

If you don't set this, an XML document with namespaces won't be enumerated correctly, and an XPath search would fail.
## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aware</td>
<td>Boolean</td>
<td>When true, the XMLDocument2 object processes the document with XML namespaces.</td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### Scoped XMLDocument2 - toString()

Returns a string containing the XML.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
</tr>
<tr>
<td>String</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>
    <one>
        <two att="xxx">abcd1234</two>
        <three boo="yah" att="yyy">1234abcd</three>
        <two>another</two>
    </one>
    <number>1234</number>
</test>";
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
gs.info(xmlDoc.toString());
```

**Output - Line breaks were added to the output for readability.**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<test>
</test>
```
<one>
<two att="xxx">abcd1234</two>
<three att="yyy" boo="yah">1234abcd</three>
<two>another</two>
</one>
<number>1234</number>
</test>

Scoped XMLDocument2 - XMLDocument2()

Creates an XMLDocument2 object.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td>None</td>
</tr>
</tbody>
</table>

Scoped XMLDocument2 - XMLDocument2( GlideScriptableInputStream inputStream)

Creates an XMLDocument2 object from an attachment stream.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputStream</td>
<td>GlideScriptableInputStream</td>
<td>The input stream the XMLDocument2 object encapsulates.</td>
</tr>
</tbody>
</table>

DOMNode - Scoped

The scoped XMLNode API allows you to query values from XML nodes. XMLNodes are extracted from XMLDocument2 objects, which contain XML strings.

There are no constructors for creating a stand alone instance of an XMLNode object. Instead, use the createElement() method of XMLDocument2, which adds a node to an existing document.

Scoped XMLNode - getAttribute(String attribute)

Gets the value of the attribute.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attribute</td>
<td>String</td>
<td>Name of the attribute.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The attribute’s value.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>" +
    "  <one>" +
    "    <two att="xxx">abcd1234</two>" +
    "    <three boo="yah" att="yyy">1234abcd</three>" +
    "    <two>another</two>" +
    "  </one>" +
    "  <number>1234</number>" +
"</test>";

var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
var node = xmlDoc.getNode('//two');
gs.info(node.getAttribute('att'));
```

Output: xxx

**Scoped XMLNode - getAttributes()**

Returns an object containing the node’s attributes as properties with values.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Object</td>
<td>Contains name-value pairs where the name is the attribute and the value is the attribute’s value.</td>
<td></td>
</tr>
</tbody>
</table>
**Scoped XMLNode - getChildNodeIterator()**  
Gets a XMLNodeIterator object that can be used to walk through the list of child nodes.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLNodeIterator</td>
<td>The node iterator object.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>" +
  "  <one>" +
  "    <two att="xxx">abcd1234</two>" +
  "    <three boo="yah" att="yyy">1234abcd</three>" +
  "    <two>another</two>" +
  "  </one>" +
  "  <number>1234</number>" +
  "</test>";
var xmlDoc = new XMLDocument2();
xmldoc.parseXML(xmlString);
var node = xmlDoc.getNode('//one');
var iter = node.getChildNodeIterator();
gs.info(iter.hasNext());
```

**Scoped XMLNode - getFirstChild()**  
Gets the node's first child node.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLNode</td>
<td>The node's first child node.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>" +
    "<one>" +
    "<two att="xxx">abcd1234</two>" +
    "<three boo="yah" att="yyy">1234abcd</three>" +
    "<two>another</two>" +
    "</one>" +
    "<number>1234</number>" +
    "</test>";
var xmlDoc = new XMLDocument2();
xmDoc.parseXML(xmlString);
var node = xmlDoc.getNode('//one');
gs.info(node.getFirstChild());
```

Output:

```
<two att="xxx">abcd1234</two>
```

Scoped XMLNode - getLastChild()

Gets the node's last child node.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLNode</td>
<td>The node's last child.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>" +
    "<one>" +
    "<two att="xxx">abcd1234</two>" +
    "<three boo="yah" att="yyy">1234abcd</three>" +
    "<two>another</two>" +
    "</one>" +
    "<number>1234</number>" +
    "</test>";
var xmlDoc = new XMLDocument2();
xmDoc.parseXML(xmlString);
var node = xmlDoc.getNode('//one');
gs.info(node.getLastChild());
```
"<number>1234</number>" +
"</test>");
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
var node = xmlDoc.getNode('//one');
gs.info(node.getLastChild());

**Output:**

<two>another</two>

### Scoped XMLNode - getNodeName()

Gets the node's name. A node's name is determined by the node type. A document-element node's name is #document. A text node's name is #text. An element node's name is the element's name.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
<td>Returns</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The node's name.</td>
</tr>
</tbody>
</table>

---

```
var xmlString = "<test>" +
    " <one>" +
    " <two att="xxx">abcd1234</two>" +
    " <three boo="yah" att="yyy">1234abcd</three>" +
    " <two>another</two>" +
  " </one>" +
    " <number>1234</number>" +
"</test>");
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
var node = xmlDoc.getNode('//two');
gs.info(node.getNodeName());
```

**Output:** two
Scoped XMLNode - getNodeValue()

Gets the node's value. A node's value is determined by the node type. Element and document-element nodes return null.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The node's value.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>" +
  "  <one>" +
  "    <two att="xxx">abcd1234</two>" +
  "    <three boo="yah" att="yyy">1234abcd</three>" +
  "    <two>another</two>" +
  "  </one>" +
  "  <number>1234</number>" +
"</test>";
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
var node = xmlDoc.getNode('//two');
gs.info(node.getNodeValue());
```

Output: null

Scoped XMLNode - getTextContent()

Gets the text content of the current node. The text content of a node consists of all the node's child text nodes

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The text content of the current node.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>" +
  "  <one>" +
  "    <two att="xxx">abcd1234</two>" +
  "    <three boo="yah" att="yyy">1234abcd</three>" +
  "    <two>another</two>" +
  "  </one>" +
  "  <number>1234</number>" +
"</test>";
var xmldoc = new XMLDocument2();
xmldoc.parseXML(xmlString);
var node = xmldoc.getNode('//one/two');
gs.info(node.getTextContent());
```

Output: abcd1234

**Scoped XMLNode - hasAttribute(String attribute)**

Determines if the node has the specified attribute.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attribute</td>
<td>String</td>
<td>The name of the attribute to check.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the node has the attribute.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>" +
  "  <one>" +
  "    <two att="xxx">abcd1234</two>" +
  "    <three boo="yah" att="yyy">1234abcd</three>" +
  "    <two>another</two>" +
  "  </one>" +
  "  <number>1234</number>" +
"</test>";
```
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
var node = xmlDoc.getNode('//two');
gs.info(node.hasAttribute('att'));

Output: true

Scoped XMLNode - toString()
Returns the string value of the current node.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The string value of the current node.</td>
</tr>
</tbody>
</table>

var xmlString = "<test>
  <one>
    <two att="xxx">abcd1234</two>
    <three att="yyy">1234abcd</three>
    <two>another</two>
  </one>
  <number>1234</number>
</test>";
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
var node = xmlDoc.getNode('//one');
gs.info(node.toString());

Output: Line breaks were added to the output.

<one>
  <two att="xxx">abcd1234</two>
  <three att="yyy" boo="yah">1234abcd</three>
  <two>another</two>
</one>
XMLNodeIterator - Scoped

The scoped XMLNodeIterator class allows you to iterate through a node of a XML document.

There are no constructors for creating a stand alone instance of a XMLNodeIterator object. To create a XMLNodeIterator object use the getChildNodeIterator() method of the XMLNode object.

Scoped XMLNodeIterator - hasNext()

Returns true if the iteration has more elements.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>True if the iteration has more elements.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>" +
  "  <one>" +
    "    <two att="xxx">abcd1234</two>" +
    "    <three boo="yah" att="yyy">1234abcd</three>" +
    "    <two>another</two>" +
  "  </one>" +
  "  <number>1234</number>" +
"</test>";
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
var node = xmlDoc.getNode('//one');
var iter = node.getChildNodeIterator();
gs.info(iter.hasNext());
```

Scoped XMLNodeIterator - next()

Gets the next element in the iteration. The returned element may be a #text node for the spaces/tabs if XML is "pretty formatted". 
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLNode</td>
<td>The next element in the iteration.</td>
</tr>
</tbody>
</table>

```javascript
var xmlString = "<test>" +
  "  <one>" +
  "    <two att="xxx">abcd1234</two>" +
  "    <three boo="yah" att="yyy">1234abcd</three>" +
  "    <two>another</two>" +
  "  </one>" +
  "  <number>1234</number>" +
  "</test>";
var xmlDoc = new XMLDocument2();
xmlDoc.parseXML(xmlString);
var node = xmlDoc.getNode('//one');
var iter= node.getChildNodeIterator();
while(iter.hasNext()) {
  var n = iter.next();
  gs.info('Node name: ' +  n.getNodeName());
  gs.info('Node value: ' +  n.getNodeValue());
}
```

### Output:

```
Node name: #text
Node value:
Node name: two
Node value: null
Node name: #text
Node value:
Node name: three
Node value: null
Node name: #text
Node value:
Node name: two
Node value: null
```
**XMLStreamingAPI - Scoped**

Build a large streaming XML payload for use in a REST or SOAP request to send bulk data to a third-party API. You can also create the payload as an XML string for a non-streaming option.

Use these methods in a Flow Designer Script step with the `sn_ih` namespace identifier. For example, you can use this API to create an XML payload in the Flow Designer Script step and pass the returned value to the REST step to send the request to a third-party service. For more information, see the Flow Designer Script step.

ℹ️ **Note**: You can only use this API within the Flow Designer environment.

There is no constructor for this class. Instead, you must call the `build()` method in the `XMLStreamingBuilder` class to return an `XMLStreamingAPI` object. For more information, see `XMLStreamingBuilder`.

**API call order**

Generate XML payloads by first instantiating a builder object with `XMLStreamingBuilder` and then calling the methods in the `XMLStreamingAPI` class:

1. **XMLStreamingBuilder**: Creates a builder object

   Use these method in the following order to create a builder object:

   1. `XMLStreamingBuilder()`: Instantiates the `XMLStreamingBuilder` object.
   2. `withAttachment()`: Optional. Creates an XML document as an attachment and stores it in the Streaming Attachments `[streaming_attachment]` table. If you don’t call this method, the API builds the payload as an XML string.
   3. `expiresAt()`: Optional. Sets a time when the attachment expires. False is the default. Must also call the `withAttachment()` method.
   4. `build()`: Returns an `XMLStreamingAPI` object.

2. **XMLStreamingAPI**: Builds the XML payload

   Use these methods in the following order to create the XML payload:
1. `startDocument()`: Creates the top-level parent element in the XML document.

2. Methods to generate child elements in the XML document, such as `writeTextElement()`, `startElement()`, and `writeArray()`.

3. Methods to generate attributes for an element, such as `writeAttribute()`, `writeNamespace()`, and `writeDtd()`.

4. `endElement()`: Closes an XML element.

5. `endDocument`: Closes the top-level parent element.

6. `getXMLString()` or `getAttachmentId()`: Returns the XML string or attachment ID that you created.

7. `close()`: Closes the XMLStreamingAPI object.

**Size limits**

Payloads generated through this API cannot exceed these size limits:

- Attachments: 200 MB
- Strings: 5 MB

The following example shows how to create an XML document and store it in the Streaming Attachments [streaming_attachment] table with a defined expiration date.

```javascript
try {
    var ttl = new GlideDateTime("2011-01-01 12:00:00");
    var builder = new sn_ih.XMLStreamingBuilder()
    .withAttachment() // Creates the XML document in streaming mode within an attachment.
    .expiresAt(ttl) // Sets an expiration date for the attachment.
    .build(); // Creates the XMLStreamingAPI object.

    builder.startDocument() // Begins generating the XML document.
    .writeTextElement("firstName","John") // Writes a "firstName" element and value.
    .writeTextElement("lastName","Smith")
    .writeTextElement("age","25")
    .startElement("address") // Adds an "address" parent element.
    .writeTextElement("streetAddress", "21 2nd Street") // Writes a child element and value.
    .writeTextElement("city", "Santa Clara")
    .writeTextElement("state", "CA")
    .writeTextElement("postalCode", "11111")
    .endElement() // Adds a closing tag for the "address" element.
}
```
Alternatively, this example shows how to use the API in the Script step and create the payload as an XML string. You can use this option to create payloads under 5 MB.

```javascript
(function execute(inputs, outputs) {

  var builder = new sn_ih.XMLStreamingBuilder().build();

  builder.startDocument()
    .enablePrettyPrint()
    .writeTextElement("firstName","John")
    .writeTextElement("lastName","Smith")
    .writeTextElement("age","25")
    .startElement("address")
      .writeTextElement("streetAddress", "21 2nd Street")
      .writeTextElement("city", "Santa Clara")
      .writeTextElement("state", "CA")
      .writeTextElement("postalCode", "11111")
    .endElement()
    .startElement("phoneNumber")
      .writeTextElement("type","home")
      .writeTextElement("number","212 555-1234")
      .writeTextElement("type","fax")
      .writeTextElement("number","646 555-4567")
    .endElement()
  .endDocument()

  outputs.payload = builder.getXMLString();
}
```
Output:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<firstName>John</firstName>
<lastName>Smith</lastName>
<age>25</age>
<address>
  <streetAddress>21 2nd Street</streetAddress>
  <city>Santa Clara</city>
  <state>CA</state>
  <postalCode>11111</postalCode>
</address>
<phoneNumber>
  <type>home</type>
  <number>212 555-1234</number>
  <type>fax</type>
  <number>646 555-4567</number>
</phoneNumber>
```

**XMLStreamingAPI - close()**

Closes the XMLStreamingAPI object. You must call this method to close the stream after building your XML document.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

The following example shows how to create an XML document and store it in the Streaming Attachments [streaming_attachment] table with a defined expiration date.

```java
try {
```
```javascript
var ttl = new GlideDateTime("2011-01-01 12:00:00");
var builder = new sn_ih.XMLStreamingBuilder()
    .withAttachment() // Creates the XML document in streaming mode within an attachment.
    .expiresAt(ttl) // Sets an expiration date for the attachment.
    .build(); // Creates the XMLStreamingAPI object.

builder.startDocument() // Begins generating the XML document.
    .writeTextElement("firstName","John") // Writes a "firstName" element and value.
    .writeTextElement("lastName","Smith")
    .writeTextElement("age","25")
    .startElement("address") // Adds an "address" parent element.
        .writeTextElement("streetAddress", "21 2nd Street") // Writes a child element and
        value.
        .writeTextElement("city", "Santa Clara")
        .writeTextElement("state", "CA")
        .writeTextElement("postalCode", "11111")
    .endElement() // Adds a closing tag for the "address" element.
    .startElement("phoneNumber")
        .writeTextElement("type","home")
        .writeTextElement("number","212 555-1234")
        .writeTextElement("type","fax")
        .writeTextElement("number","646 555-4567")
    .endElement()
.endDocument() // Stops generating the XML document.

gs.log(builder.getAttachmentId()); // Returns the sys_id of the attachment.
} catch (err) {
    gs.log(err);
} finally {
    builder.close();
}
```

**XMLStreamingAPI - disablePrettyPrint()**

Ends pretty print XML formatting.

Before calling this method, you must first call `enablePrettyPrint()` to add XML formatting to a section.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

The following example shows how to add pretty print formatting to the address element.

```javascript
try {
  var ttl = new GlideDateTime("2011-01-01 12:00:00");
  var builder = new sn_ih.XMLStreamingBuilder()
    .withAttachment()
    .expiresAt(ttl)
    .build();

  builder.startDocument()
    .writeTextElement("firstName", "John")
    .writeTextElement("lastName", "Smith")
    .writeTextElement("age", "25")
    .enablePrettyPrint()
    .startElement("address")
      .writeTextElement("streetAddress", "21 2nd Street")
      .writeTextElement("city", "Santa Clara")
      .writeTextElement("state", "CA")
      .writeTextElement("postalCode", "11111")
    .endElement()
    .disablePrettyPrint()
    .startElement("phoneNumber")
      .writeTextElement("type", "home")
      .writeTextElement("number", "212 555-1234")
      .writeTextElement("type", "fax")
      .writeTextElement("number", "646 555-4567")
    .endElement()
  .endDocument()

  gs.log(builder.getAttachmentId());
} catch (err) {
  gs.log(err);
} finally {
  builder.close();
}
```
XMLStreamingAPI - enablePrettyPrint()

Adds pretty print formatting to an XML element or tree of elements.

Use the disablePrettyPrint() method to end the formatting.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

The following example shows how to add pretty print formatting to the address element.

```javascript
try {
    var ttl = new GlideDateTime("2011-01-01 12:00:00");
    var builder = new sn_ih.XMLStreamingBuilder()
        .withAttachment()
        .expiresAt(ttl)
        .build();

    builder.startDocument()
        .writeTextElement("firstName","John")
        .writeTextElement("lastName","Smith")
        .writeTextElement("age","25")
        .enablePrettyPrint()
        .startElement("address")
            .writeTextElement("streetAddress", "21 2nd Street")
            .writeTextElement("city", "Santa Clara")
            .writeTextElement("state", "CA")
            .writeTextElement("postalCode", "11111")
        .endElement()
        .disablePrettyPrint()
        .startElement("phoneNumber")
            .writeTextElement("type","home")
            .writeTextElement("number","212 555-1234")
            .writeTextElement("type","fax")
            .writeTextElement("number","646 555-4567")
} catch (err) {
    console.err(err);}
```
XMLStreamingAPI - endDocument()

Ends the structure of your XML document.

After calling the `startDocument()` method and organizing your streaming XML document, call the `endDocument()` method at the end of your document's structure. You must use these two methods together to successfully build your streaming XML document's structure.

## Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

## Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

The following example shows how to create an XML document containing elements about a user.

```javascript
try {
  var ttl = new GlideDateTime('2011-01-01 12:00:00');
  var builder = new sn_ih.XMLStreamingBuilder().withAttachment().expiresAt(ttl);
  var streamingDocument = builder.build();

  streamingDocument.startDocument('Employee')
    .writeTextElement('firstName', 'John')
    .writeTextElement('lastName', 'Smith')
    .writeTextElement('age', '25')
    .endDocument();
  gs.log(streamingDocument.getAttachmentId());
}
```
XMLStreamingAPI - endElement()

Adds a closing tag to an XML element.

Use the following methods in this sequence to create a valid XML element:

1. Use the startElement() method to add a starting tag.
2. Use the endElement() method to add the closing tag.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

The following example shows how to build a parent element named address and then write four child elements.

```javascript
try {
  var ttl = new GlideDateTime("2011-01-01 12:00:00");
  var builder = new sn_ih.XMLStreamingBuilder()
    .withAttachment()
    .expiresAt(ttl)
    .build();

  builder.startDocument()
    .startElement("address")
    .writeTextElement("streetAddress", "21 2nd Street")
    .writeTextElement("city", "Santa Clara")
    .writeTextElement("state", "CA")
    .writeTextElement("postalCode", "11111")
    .endElement()
  .endDocument();
}
```
XMLStreamingAPI - getXMLString()

Returns the XML document as a string.

To return the XML document as a string, don't call the getAttachmentId() method in the XMLStreamingBuilder class. For more information, see XMLStreamingBuilder - Scoped.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>XML document created using the XMLStreamingAPI methods, as a string.</td>
</tr>
</tbody>
</table>

The following example shows how to create an XML document and then return it as a string.

```javascript
(function execute(inputs, outputs) {

  var builder = new sn_ih.XMLStreamingBuilder().build();

  builder.startDocument()
    .enablePrettyPrint()
    .writeTextElement("firstName", "John")
    .writeTextElement("lastName", "Smith")
    .writeTextElement("age", "25")
    .startElement("address")
      .writeTextElement("streetAddress", "21 2nd Street")
      .writeTextElement("city", "Santa Clara")
      .writeTextElement("state", "CA")
      .writeTextElement("postalCode", "11111")
}
```
Output:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<firstName>John</firstName>
<lastName>Smith</lastName>
<age>25</age>
<address>
    <streetAddress>21 2nd Street</streetAddress>
    <city>Santa Clara</city>
    <state>CA</state>
    <postalCode>11111</postalCode>
</address>
<phoneNumber>
    <type>home</type>
    <number>212 555-1234</number>
    <type>fax</type>
    <number>646 555-4567</number>
</phoneNumber>
```

**XMLStreamingAPI - startDocument(String rootElement, Object namespaceDefinitionMap)**

Begins building an XML document.

After calling the `build()` method, call the `startDocument()` method to start organizing your XML document. You must also call the `endDocument` method at the end of your document's structure.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rootElement</td>
<td>String</td>
<td>Optional. Root element, or top-level parent element, for your XML document.</td>
</tr>
<tr>
<td>namespaceDefinitionMap</td>
<td>Object</td>
<td>Optional. Map of keys and values for the namespaces and their associated values in a subsequent list of elements. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{ 'namespaceOne':'namespaceValue', 'namespaceTwo':'namespaceValue' }</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

The following example shows how to create an XML document containing elements with information about an employee.

```javascript
try {
    var ttl = new GlideDateTime('2011-01-01 12:00:00');
    var builder = new sn_ih/XMLStreamingBuilder().withAttachment().expiresAt(ttl);
    var streamingDocument = builder.build();

    streamingDocument.startDocument('Employee')
        .writeTextElement('firstName', 'John')
        .writeTextElement('lastName', 'Smith')
        .writeTextElement('age', '25')
        .endDocument();
    gs.log(streamingDocument.getAttachmentId());
} catch (err) {
    gs.log(err);
} finally {
    streamingDocument.close();
}
```
XMLStreamingAPI - startElement(String name, Object namespaceMap, Object attributeMap, String prefix)

Adds a starting tag for an XML element.

Use the following methods in this sequence to create a valid XML element:

1. Use the `startElement()` method to add a starting tag.
2. Use the `endElement()` method to add the closing tag.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the XML element.</td>
</tr>
<tr>
<td>namespaceMap</td>
<td>Object</td>
<td>Optional. Map of keys and values for the namespaces and their associated values in a subsequent list of elements. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'namespaceOne':'namespaceValue',</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'namespaceTwo':'namespaceValue'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td>attributeMap</td>
<td>Object</td>
<td>Optional. Map of keys and values for the attributes and their associated values in a subsequent list of elements.</td>
</tr>
<tr>
<td>prefix</td>
<td>String</td>
<td>Optional. Prefix for the XML element.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

The following example shows how to build a parent element named `address` and then write four child elements.

```java
try {
    var ttl = new GlideDateTime("2011-01-01 12:00:00");
    var builder = new sn_ih.XMLStreamingBuilder()
        .withAttachment()
        .expiresAt(ttl)
        .build();
```
XMLStreamingAPI - `writeArray(String elementName, Array data, String wrappingElement)`

Adds a list of nested elements with predefined text to your streaming XML document.

After calling the `startDocument()` method, you can call the `writeArray()` method to add a block of nested elements to your streaming XML document.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>elementName</code></td>
<td>String</td>
<td>Name of the XML element associated with each string listed in the <code>data</code> array.</td>
</tr>
<tr>
<td><code>data</code></td>
<td>Array</td>
<td>List of values to assign to each element nested inside <code>wrappingElement</code>.</td>
</tr>
<tr>
<td><code>wrappingElement</code></td>
<td>String</td>
<td>Parent element containing each <code>elementName</code>.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

The following example shows how to build a parent element named `officeLocations`, and then nest an array of five `city` elements.
try {
    var ttl = new GlideDateTime("2011-01-01 12:00:00");
    var builder = new sn_ih.XMLStreamingBuilder()
        .withAttachment()
        .expiresAt(ttl)
        .build();

    builder.startDocument()
        .writeArray('city', ['Santa Clara','San Diego','Chicago','Sydney','London'],
        'officeLocations')
        .endDocument()

    gs.log(builder.getAttachmentId());
} catch (err) {
    gs.log(err);
} finally {
    builder.close();
}

**XMLStreamingAPI - writeAttribute(String name, String value)**

Adds an attribute to an element in your XML document.

After calling the `startDocument()`, `startElement()`, or `writeTextElement()` method, you can call the `writeAttribute()` method to add an attribute to the associated XML element.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the XML element’s attribute.</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
<td>Value for the XML element’s attribute.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

This example adds an attribute named `idNumber` to the `employee` element.

```javascript
try {
    var ttl = new GlideDateTime('2011-01-01 12:00:00');
    var builder = new sn_ih.XMLStreamingBuilder().withAttachment().expiresAt(ttl);
    builder.startDocument()
        .writeArray('city', ['Santa Clara','San Diego','Chicago','Sydney','London'],
        'officeLocations')
        .endDocument()
    gs.log(builder.getAttachmentId());
} catch (err) {
    gs.log(err);
} finally {
    builder.close();
}
```
var streamingDocument = builder.build();

streamingDocument.startDocument('Employee')
  .writeAttribute('idNumber', '12345')
  .writeTextElement('firstName', 'John')
  .writeTextElement('lastName', 'Smith')
  .writeTextElement('age', '25')
  .endDocument();

gs.log(streamingDocument.getAttachmentId());
} catch (err) {
  gs.log(err);
} finally {
  streamingDocument.close();
}

**XMLStreamingAPI - writeAttributes(Object attributeMap)**

Adds attributes to an element in your XML document.

After calling the `startDocument()`, `startElement()`, or `writeTextElement()` method, you can call the `writeAttributes()` method to add attributes to the associated XML element.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributeMap</td>
<td>Object</td>
<td>Map of keys and values containing attribute names and values to associate with the XML element. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

This example adds attributes named `idNumber`, `officeLocation`, and `department` to the `employee` element.
try {
    var ttl = new GlideDateTime('2011-01-01 12:00:00');
    var builder = new sn_ih.XMLStreamingBuilder().withAttachment().expiresAt(ttl);
    var streamingDocument = builder.build();
    streamingDocument.startDocument('Employee')
        .writeAttributes({'idNumber':'12345', 'officeLocation':'San Diego',
                         'department':'Sales'})
        .writeTextElement('firstName', 'John')
        .writeTextElement('lastName', 'Smith')
        .writeTextElement('age', '25')
        .endDocument();
    gs.log(streamingDocument.getAttachmentId());
} catch (err) {
    gs.log(err);
} finally {
    streamingDocument.close();
}

XMLStreamingAPI - writeCData(String data)

Adds CDATA to your XML document.

After calling the writeCDataElement() method, you can call the writeCData() method to add CDATA within the element.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data</td>
<td>String</td>
<td>Value to include after the CDATA keyword in your CDATA element.</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

This example adds CDATA to the CDATA element timeWorked.

try {
    var ttl = new GlideDateTime('2011-01-01 12:00:00');
    var builder = new sn_ih.XMLStreamingBuilder().withAttachment().expiresAt(ttl);
    var streamingDocument = builder.build();
}
streamingDocument.startDocument('Employee')
    .writeTextElement('firstName', 'John')
    .writeTextElement('lastName', 'Smith')
    .writeTextElement('age', '25')
    .writeCDataElement('timeWorked')
    .writeCData('< 2 years')
    .endDocument();
gs.log(streamingDocument.getAttachmentId());
} catch (err) {
    gs.log(err);
} finally {
    streamingDocument.close();
}

XMLStreamingAPI - writeCDataElement(String name, String data, Object prefix)
Adds a CDATA element to your XML document.

After calling the startDocument() method, you can call the writeCDataElement() method to add a CDATA element to your XML document.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the CDATA element.</td>
</tr>
<tr>
<td>data</td>
<td>String</td>
<td>Optional. Type of data to parse the CDATA element as.</td>
</tr>
<tr>
<td>prefix</td>
<td>Object</td>
<td>Optional. Map of child elements and values that the CDATA element includes. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'prefixOne':'prefixValue',</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'prefixTwo':'prefixValue'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You must associate an XML element's prefix with a namespace using writeNamespace().</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>
This example uses a document type definition named `address` to define an internal document type definition for the XML document.

```javascript
try {
  var ttl = new GlideDateTime("2011-01-01 12:00:00");
  var builder = new sn_ih.XMLStreamingBuilder()
    .withAttachment()
    .expiresAt(ttl)
    .build();

  builder.startDocument()
    .writeDtd('address')
    .writeCDataElement('home', '#PCDATA', {'streetAddress', 'city', 'state', 'postalCode'})
      .writeTextElement("streetAddress", "21 2nd Street")
      .writeTextElement("city", "Santa Clara")
      .writeTextElement("state", "CA")
      .writeTextElement("postalCode", "11111")
    .endDocument()

  gs.log(builder.getAttachmentId());
} catch (err) {
  gs.log(err);
} finally {
  builder.close();
}
```

**XMLStreamingAPI - writeCharacters(String text)**

Adds text to your XML document.

Use the `writeCharacters()` method to insert string data to a section in your XML document.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>String</td>
<td>Text to add to a section of your XML document.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>
The following example shows how to add text values to elements in your XML document.

```javascript
try {
    var ttl = new GlideDateTime('2011-01-01 12:00:00');
    var builder = new sn_ih.XMLStreamingBuilder().withAttachment().expiresAt(ttl);
    var streamingDocument = builder.build();

    streamingDocument.startDocument('Employee')
       .startElement('firstName')
       .writeCharacters('John')
       .EndElement()
       .startElement('lastName')
       .writeCharacters('Smith')
       .EndElement()
       .endDocument();
    gs.log(streamingDocument.getAttachmentId());
} catch (err) {
    gs.log(err);
} finally {
    streamingDocument.close();
}
```

**XMLStreamingAPI - writeComment(String comment)**

Adds a comment to your XML document.

After calling the `startDocument()` method, you can call the `writeComment()` method to add a comment to your XML document.

<table>
<thead>
<tr>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>comment</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>XMLStreamingAPI</td>
</tr>
</tbody>
</table>

The following example shows how to add a comment to an XML document.

```javascript
try {
    var ttl = new GlideDateTime('2011-01-01 12:00:00');
```
var builder = new sn_ih.XMLStreamingBuilder().withAttachment().expiresAt(ttl);
var streamingDocument = builder.build();

streamingDocument.startDocument('Employee')
    .writeComment('Element for information related to active employees.')
    .writeTextElement('firstName', 'John')
    .writeTextElement('lastName', 'Smith')
    .writeTextElement('age', '25')
    .endDocument();
gs.log(streamingDocument.getAttachmentId());
} catch (err) {
    gs.log(err);
} finally {
    streamingDocument.close();
}

**XMLStreamingAPI - writeDtd(String dtd)**

Adds a document type definition to your XML document.

After calling the `startDocument()` method, you can call the `writeDtd()` method to add a valid XML document type definition to your XML document.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dtd</td>
<td>String</td>
<td>Name of a valid XML document type definition.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

This example uses a document type definition named *address* to define an internal document type definition for the XML document.

```javascript
try {
    var ttl = new GlideDateTime("2011-01-01 12:00:00");
    var builder = new sn_ih.XMLStreamingBuilder()
        .withAttachment()
        .expiresAt(ttl)
        .build();
```
XMLStreamingAPI - writeNamespace(String prefix, String namespaceURI)

Adds a namespace to an element in your XML document.

After calling the startDocument(), startElement(), or writeTextElement() method, you can call the writeNamespace() method to add a namespace to the associated XML element.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>prefix</td>
<td>String</td>
<td>Prefix for the XML namespace.</td>
</tr>
<tr>
<td>namespaceURI</td>
<td>String</td>
<td>Optional. URI for the namespace.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

The following example shows how to add a namespace and URI to the company root element, and then assign the prefix to the nested companyName element.

```javascript
try {
  var ttl = new GlideDateTime('2011-01-01 12:00:00');
  var builder = new sn_ih.XMLStreamingBuilder().withAttachment().expiresAt(ttl);
  var streamingDocument = builder.build();
...
```javascript
streamingDocument.startDocument('company')
   .writeNamespace('x','https://www.servicenow.com')
   .writeTextElement('companyName', 'ServiceNow')
   .writeNamespace('x')
   .endDocument();
gs.log(streamingDocument.getAttachmentId());
}
```

**XMLStreamingAPI - writeNamespaces(Object namespaceMap)**

Adds namespaces to the root element in your XML document.

After calling the `startDocument()` or `startElement()` method, you can call the `writeNamespaces()` method to declare namespaces for the associated XML element.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>namespaceMap</td>
<td>Object</td>
<td>Map of keys and values containing namespace prefixes and URIs to associate with the root element of the XML document. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>{ 'namespaceOne': 'namespaceValue', 'namespaceTwo': 'namespaceValue' }</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>

This example adds two namespaces and URIs to the `company` root element, and then assigns the appropriate prefixes to the nested elements.

```javascript
try {
    var ttl = new GlideDateTime('2011-01-01 12:00:00');
    var builder = new sn_ih.XMLStreamingBuilder().withAttachment().expiresAt(ttl);  
    var streamingDocument = builder.build();
}
```
XMLStreamingAPI - writeTextElement(String name, String text, Object prefix)

Adds a single XML element to your XML document.

After calling the `startDocument()` method, you can call the `writeTextElement()` method to add a single XML element to your XML document’s structure.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>String</td>
<td>Name of the XML element.</td>
</tr>
<tr>
<td>text</td>
<td>String</td>
<td>Value for the XML element.</td>
</tr>
<tr>
<td>prefix</td>
<td>Object</td>
<td>Optional. Map of prefixes and values associated with the XML element. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>`{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'prefixOne': 'prefixValue',</td>
</tr>
<tr>
<td></td>
<td></td>
<td>'prefixTwo': 'prefixValue'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>

You must associate an XML element's prefix with a namespace using `writeNamespace()`.

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingAPI</td>
<td>Streaming XML object for constructing the payload.</td>
</tr>
</tbody>
</table>
The following example shows how to create an XML document containing three elements with information about an employee.

```javascript
try {
    var ttl = new GlideDateTime('2011-01-01 12:00:00');
    var builder = new sn_ih.XMLStreamingBuilder().withAttachment().expiresAt(ttl);
    var streamingDocument = builder.build();

    streamingDocument.startDocument('Employee')
        .writeTextElement('firstName', 'John')
        .writeTextElement('lastName', 'Smith')
        .writeTextElement('age', '25')
        .endDocument();
    gs.log(streamingDocument.getAttachmentId());
} catch (err) {
    gs.log(err);
} finally {
    streamingDocument.close();
}
```

**XMLStreamingBuilder - Scoped**

Create a builder object to build a large XML payload for use in a REST or SOAP request to send bulk data to a third-party API. You can also create the payload as an XML string for a non-streaming option.

Use these methods in a Flow Designer Script step with the `sn_ih` namespace identifier. For example, you can use this API to create an XML payload in the Flow Designer Script step and pass the returned value to the REST step to send the request to a third-party service. For more information, see the Flow Designer Script step.

⚠️ **Note:** You can only use this API within the Flow Designer environment.

**API call order**

Generate XML payloads by first instantiating a builder object with `XMLStreamingBuilder` and then calling the methods in the `XMLStreamingAPI` class:

1. `XMLStreamingBuilder`: Creates a builder object

   Use these method in the following order to create a builder object:
1. XMLStreamingBuilder(): Instantiates the XMLStreamingBuilder object.

2. withAttachment(): Optional. Creates an XML document as an attachment and stores it in the Streaming Attachments [streaming_attachment] table. If you don't call this method, the API builds the payload as an XML string.

3. expiresAt(): Optional. Sets a time when the attachment expires. False is the default. Must also call the withAttachment() method.

4. build(): Returns an XMLStreamingAPI object.

2. XMLStreamingAPI: Builds the XML payload

Use these methods in the following order to create the XML payload:

1. startDocument(): Creates the top-level parent element in the XML document.

2. Methods to generate child elements in the XML document, such as writeTextElement(), startElement(), and writeArray().

3. Methods to generate attributes for an element, such as writeAttribute(), writeNamespace(), and writeDtd().

4. endElement(): Closes an XML element.

5. endDocument(): Closes the top-level parent element.

6. getXMLString() or getAttachmentId(): Returns the XML string or attachment ID that you created.

7. close(): Closes the XMLStreamingAPI object.

Size limits

Payloads generated through this API cannot exceed these size limits:

- Attachments: 200 MB
- Strings: 5 MB

The following example shows how to create an XML document and store it in the Streaming Attachments [streaming_attachment] table with a defined expiration date.

```java
try {
    var ttl = new GlideDateTime("2011-01-01 12:00:00");
    var builder = new sn_ih.XMLStreamingBuilder()
```
builder.startDocument() // Begins generating the XML document.
.builder.writeHeadVersion()
.builder.writeStartElement("firstName","John") // Writes a "firstName" element and value.
.builder.writeTextElement("lastName","Smith")
.builder.writeTextElement("age","25")
.builder.writeStartElement("address") // Adds an "address" parent element.
.builder.writeTextElement("streetAddress", "21 2nd Street") // Writes a child element and value.
.builder.writeTextElement("city", "Santa Clara")
.builder.writeTextElement("state", "CA")
.builder.writeTextElement("postalCode", "11111")
.builder.endElement() // Adds a closing tag for the "address" element.
.builder.startElement("phoneNumber")
.builder.writeTextElement("type","home")
.builder.writeTextElement("number","212 555-1234")
.builder.writeTextElement("type","fax")
.builder.writeTextElement("number","646 555-4567")
.builder.endElement()
.builder.endDocument() // Stops generating the XML document.

gs.log(builder.getAttachmentId()); // Returns the sys_id of the attachment.
})
} catch (err) {
    gs.log(err);
} finally {
    builder.close();
}
Outputs.payload = builder.getXMLString();

Output:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<firstName>John</firstName>
<lastName>Smith</lastName>
<age>25</age>
<address>
  <streetAddress>21 2nd Street</streetAddress>
  <city>Santa Clara</city>
  <state>CA</state>
  <postalCode>11111</postalCode>
</address>
<phoneNumber>
  <type>home</type>
  <number>212 555-1234</number>
  <type>fax</type>
  <number>646 555-4567</number>
</phoneNumber>
```

**XMLStreamingBuilder - build()**

Returns an XMLStreamingAPI object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The following example shows how to create an XML document and store it in the Streaming Attachments [streaming_attachment] table with a defined expiration date.

```java
try {
    var ttl = new GlideDateTime("2011-01-01 12:00:00");
    var builder = new sn_ih.XMLStreamingBuilder()
        .withAttachment() // Creates the XML document in streaming mode within an attachment.
        .expiresAt(ttl) // Sets an expiration date for the attachment.
        .build(); // Creates the XMLStreamingAPI object.

    builder.startDocument() // Begins generating the XML document.
        .writeTextElement("firstName","John") // Writes a "firstName" element and value.
        .writeTextElement("lastName","Smith")
        .writeTextElement("age","25")
        .startElement("address") // Adds an "address" parent element.
            .writeTextElement("streetAddress","21 2nd Street") // Writes a child element and value.
                .writeTextElement("city","Santa Clara")
                .writeTextElement("state","CA")
                .writeTextElement("postalCode","11111")
            .endElement() // Adds a closing tag for the "address" element.
        .startElement("phoneNumber")
            .writeTextElement("type","home")
            .writeTextElement("number","212 555-1234")
            .writeTextElement("type","fax")
            .writeTextElement("number","646 555-4567")
        .endElement()
    .endDocument() // Stops generating the XML document.

    gs.log(builder.getAttachmentId()); // Returns the sys_id of the attachment.
} catch (err) {
    gs.log(err);
} finally {
    builder.close();
}
```
(XML: Streaming: Builder - expiresAt(Object expiresAt)

Sets a time when the attachment expires. Must also call the `withAttachment()` method.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expiresAt</td>
<td>GlideDateTime</td>
<td>Object that is set when the attachment expires.</td>
</tr>
</tbody>
</table>

- Minimum value: 7200 seconds, or two hours, from the time the attachment is created. This is the default value if you don’t call the `expiresAt()` method.
- Maximum value: 172800 seconds, or 48 hours, from the time the attachment is created.

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingBuilder</td>
<td>Builder object used to initiate the XML payload.</td>
</tr>
</tbody>
</table>

The following example shows how to create an XML document and store it in the Streaming Attachments [streaming_attachment] table with a defined expiration date.

```java
try {
    var ttl = new GlideDateTime("2011-01-01 12:00:00");
    var builder = new sn_ih.XMLStreamingBuilder()
        .withAttachment() // Creates the XML document in streaming mode within an attachment.
        .expiresAt(ttl) // Sets an expiration date for the attachment.
        .build(); // Creates the XMLStreamingAPI object.

    builder.startDocument() // Begins generating the XML document.
        .writeTextElement("firstName","John") // Writes a "firstName" element and value.
        .writeTextElement("lastName","Smith")
        .writeTextElement("age","25")
        .startElement("address") // Adds an "address" parent element.
        .writeTextElement("streetAddress", "21 2nd Street") // Writes a child element and value.
        .writeTextElement("city", "Santa Clara")
        .writeTextElement("state", "CA")
```
XMLStreamingBuilder - withAttachment()

Creates an XML document as an attachment and stores it in the Streaming Attachments [streaming_attachment] table. If you don’t call this method, the API creates the XML document as a string.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLStreamingBuilder</td>
<td>Builder object used to initiate the XML payload.</td>
</tr>
</tbody>
</table>

The following example shows how to create an XML document and store it in the Streaming Attachments [streaming_attachment] table with a defined expiration date.

```javascript
try {
    var ttl = new GlideDateTime("2011-01-01 12:00:00");
    var builder = new sn_ih.XMLStreamingBuilder()
        .withAttachment() // Creates the XML document in streaming mode within an attachment.
        .expiresAt(ttl) // Sets an expiration date for the attachment.
    gs.log(builder.getAttachmentId()); // Returns the sys_id of the attachment.
} catch (err) {
    gs.log(err);
} finally {
    builder.close();
}
```
This example shows how to build the XML payload and save it as a string.

```javascript
(function execute(inputs, outputs) {

  var builder = new sn_ih.XMLStreamingBuilder().build();

  builder.startDocument();
  .enablePrettyPrint()
  .writeTextElement("firstName","John")
  .writeTextElement("lastName","Smith")
  .writeTextElement("age","25")
  .startElement("address")
  .writeTextElement("streetAddress", "21 2nd Street")
  .writeTextElement("city", "Santa Clara")
  .writeTextElement("state", "CA")
  .writeTextElement("postalCode", "11111")
  .endElement() // Adds a closing tag for the "address" element.
  .startElement("phoneNumber")
  .writeTextElement("type","home")
  .writeTextElement("number", "212 555-1234")
  .writeTextElement("type","fax")
  .writeTextElement("number", "646 555-4567")
  .endElement()
  .endDocument() // Stops generating the XML document.

  gs.log(builder.getAttachmentId()); // Returns the sys_id of the attachment.
} catch (err) {
    gs.log(err);
} finally {
    builder.close();
}
```

Output:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<firstName>John</firstName>
<lastName>Smith</lastName>
<age>25</age>
<address>
  <streetAddress>21 2nd Street</streetAddress>
  <city>Santa Clara</city>
  <state>CA</state>
  <postalCode>11111</postalCode>
</address>
<phoneNumber>
  <type>home</type>
  <number>212 555-1234</number>
  <type>fax</type>
  <number>646 555-4567</number>
</phoneNumber>
```

**XMLStreamingBuilder - XMLStreamingBuilder()**

Instantiates the XMLStreamingBuilder object.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This example shows how to instantiate a `builder` object.

```javascript
var builder = new sn_ih.XMLStreamingBuilder()
```
XMLUtilJS - Global

Provides XML utilities for JavaScript to be used with Discovery scripts.

Use this script include in any server-side discovery script where you need XML utilities.

Access these methods using the static variable XMLUtilJS.

XMLUtilJS - escapeForXMLText(String text)

Provides escape text for a given string.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>String</td>
<td>The text to format.</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The formatted text.</td>
</tr>
</tbody>
</table>

XMLUtilJS - stringToValue(String str)

Converts a string to an XML value.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>str</td>
<td>String</td>
<td>The string to convert</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The specified string converted to XML.</td>
</tr>
</tbody>
</table>

XMLUtilJS - unescapeForXMLText(String text)

Provides un-escaped text for a given string.
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>String</td>
<td>The text to clean up.</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The cleaned up string.</td>
</tr>
</tbody>
</table>

**XMLUtilJS - valueToString(String XMLvalue)**

Converts an XML value to a string.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLvalue</td>
<td>String</td>
<td>The XML to convert</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The XML value converted to a string.</td>
</tr>
</tbody>
</table>

### Scripts

Use scripts to extend your instance beyond standard configurations. With scripts, you may automate processes, add functionality, integrate your instance with an outside application and more.

APIs (Application Programming Interfaces) provide classes and methods that you can use in scripts to define functionality. ServiceNow provides APIs as JavaScript classes, web services, and other points of connection for integrations. Note that you cannot access commonly used JavaScript objects (such as DOM or Window). Jelly scripts are also used in some modules. Jelly is used to turn XML into HTML and may include both client-side and server-side scripts.

Scripts may be server-side (run on the server or database), client-side (run in the user's browser), or run on the MID server.

⚠️ **Note:** When you are writing scripts, you cannot use reserved words.
Understand JavaScript before you begin customizing your instance, and with Jelly if you intend to deploy Jelly scripts.

Server-side scripts

Perform database operations. For example, use a server-side script to update a record. Create a script in a scoped application or in the global scope. Each execution context includes a set of available APIs.

Scoped environment

Use scoped APIs when scripting in a scoped application.Scoped Glide APIs do not include all the methods included in the global Glide APIs, and you cannot call a global Glide API in a scoped application.

Global environment

The global scope is a special application scope that identifies applications developed prior to application scoping, or applications intended to be accessible to all other global applications. Use global APIs when scripting in the global scope.

To learn more about server-side scripting, see Server-side scripting. To learn more about application scope, see Application scope.

Client-side scripts

Make changes to the appearance of forms, display different fields based on values that are entered, or change other custom display options.

- **onLoad** client scripts run when the form or page is loaded
- **onChange** client scripts run when something specific gets changed AND also when the form or page loads
- **onSubmit** client scripts run when the form is submitted

Client Scripts can also be called by other scripts or modules, including UI policies. To learn more about client-side scripting, see Client-side scripting.

Available script types

Scripts can be used in many places. The most important detail is whether the script runs on the client or the server.
### Script types and where they run

<table>
<thead>
<tr>
<th>Script</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access Control</strong></td>
<td>Determines whether access will be granted for a specified operation to a specific entity.</td>
</tr>
<tr>
<td></td>
<td>• type of entity being secured</td>
</tr>
<tr>
<td></td>
<td>• operation being secured</td>
</tr>
<tr>
<td></td>
<td>• unique identifier describing the object</td>
</tr>
<tr>
<td></td>
<td>Can be defined by roles, conditional expressions or scripts.</td>
</tr>
<tr>
<td><strong>Ajax Scripts</strong></td>
<td>Enables the client to get data from the server to dynamically incorporate into a page without reloading the whole page.</td>
</tr>
<tr>
<td></td>
<td>• Ajax Client Scripts request that information be returned, or that action be taken, or sometimes both</td>
</tr>
<tr>
<td></td>
<td>• Ajax Server Scripts fulfill Ajax Client Script requests</td>
</tr>
<tr>
<td><strong>Business Rules</strong></td>
<td>Customizes system behavior</td>
</tr>
<tr>
<td></td>
<td>• runs when a database action occurs (query, insert, update or delete)</td>
</tr>
<tr>
<td></td>
<td>• the script may run</td>
</tr>
<tr>
<td></td>
<td>◦ before or after the database action is performed (runs as part of the database operation)</td>
</tr>
<tr>
<td></td>
<td>◦ asynchronously (at some point after the database operation)</td>
</tr>
<tr>
<td></td>
<td>◦ on display (when displaying the data in a form)</td>
</tr>
<tr>
<td><strong>Service Catalog UI policies</strong></td>
<td>Defines the display of a variable set or a catalog item (from the service catalog)</td>
</tr>
</tbody>
</table>
### Script types and where they run (continued)

<table>
<thead>
<tr>
<th>Script</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Client Scripts**| Used for making changes to the appearance of forms, displaying different fields based on values that are entered or other custom display options.  
• onLoad means the Client Script runs when the form or page is loaded  
• onChange means the Client Script runs when something specific gets changed AND also when the form or page loads  
• onSubmit means the Client Script runs when the form is submitted  
Client Scripts can also be called by other scripts or modules, including UI policies. |
| **Script actions**| Contains scripts which run when an event occurs, for example  
• approval is cancelled  
• change is approved  
• problem is assigned  
Can have a condition which must be true for the script to run. Commonly used to call a Script Include. |
| **Script Includes**| Contains scripts which can be functions or classes. These scripts run only when called by other scripts (often Business Rules).  
Any server script which is complicated or reusable should be a Script Include (especially complicated Business Rules). |
| **Transform Maps**| Used for importing data.  
• defines mapping relationships between tables  
• can use Business Rules, other scripts and/or other options to import that data  
Do not always include scripts. |
| **UI Actions**    | Creates the ability to choose a specific action such as clicking a button or a link.  
UI Actions put these items on forms and lists:  
• buttons  
• links |

</tr>
</thead>
<tbody>
<tr>
<td><strong>client</strong> - action</td>
<td>Scripts run on the client.</td>
</tr>
<tr>
<td><strong>server</strong> - dynamic</td>
<td>Dynamic action scripts run on the server.</td>
</tr>
<tr>
<td><strong>server</strong> - all</td>
<td>All conditions run on the server.</td>
</tr>
</tbody>
</table>

**Note:** If you use a left-handed mouse configuration, right-click means “click the other button.”

#### UI Macros

Contains modular, reusable components that can contain Jelly and are called by UI pages. They also contain different types of scripts and may be called multiple times on the same page.

**Note:** Jelly turns XML into HTML.
### Script types and where they run (continued)

<table>
<thead>
<tr>
<th>Script</th>
<th>Description</th>
</tr>
</thead>
</table>
| UI Pages | Used to create and display pages, forms, dialogs, lists and other UI components. Can be displayed on a standalone basis, or called as a usable component, as part of a larger page. Can contain:  
- Client Scripts,  
- processing scripts (which are server scripts),  
- HTML,  
- Jelly,  
- UI Macros,  
- and also can call other scripts. |

<tr>
<td>Validation</td>
<td>Validates that values are in a specified format.</td>
</tr>
<tr>
<td>Scripts</td>
<td>For example, a validation script can verify that the only value allowed in a specified field is an integer.</td>
</tr>
<tr>
<td>Workflow editor</td>
<td>Used to create or change a workflow. Scripts can be run at any point in a workflow or different scripts can be run at different points. Scripts also can be found inside every workflow activity and can be modified (although do so with extreme caution).</td>
</tr>
</tbody>
</table>
Glide class overview

The ServiceNow Glide classes expose JavaScript APIs that enable you to conveniently work with tables using scripts.

Using the Glide APIs, you can perform database operations without writing SQL queries, display UI pages, and define UI actions. The following tables provide brief descriptions of the Glide classes and links to detailed information.

Server-side Glide classes

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord</td>
<td>Use this class for database operations instead of writing SQL queries. GlideRecord is a special Java class that can be used in JavaScript exactly as if it were a native JavaScript class. A GlideRecord is an object that contains records from a single table. See GlideRecord.</td>
</tr>
<tr>
<td>GlideElement</td>
<td>Use this class to operate on the fields of the current GlideRecord. See GlideElement.</td>
</tr>
<tr>
<td>GlideSystem</td>
<td>Use this class to get information about the system. See GlideSystem.</td>
</tr>
<tr>
<td>GlideAggregate</td>
<td>Use this class to perform database aggregation queries, such as COUNT, SUM, MIN, MAX, and AVG, for creating customized reports or calculations in calculated fields. See GlideAggregate.</td>
</tr>
<tr>
<td>GlideDateTime</td>
<td>Use this class to perform date-time operations, such as date-time calculations, formatting a date-time, or converting between date-time formats. See GlideDateTime.</td>
</tr>
</tbody>
</table>

Client-side Glide Classes

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideAjax</td>
<td>Use this class to execute server-side code from the client. See GlideAjax.</td>
</tr>
<tr>
<td>GlideDialogWindow</td>
<td>Use this class to display a dialog window. See GlideDialogWindow.</td>
</tr>
<tr>
<td>GlideForm</td>
<td>Use this class to customize forms. See GlideForm.</td>
</tr>
<tr>
<td>GlideList2</td>
<td>Use this class to customize (v2) lists, including normal lists and related lists. See GlideList2.</td>
</tr>
</tbody>
</table>
Client-side Glide Classes (continued)

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideMenu</td>
<td>Use this class to customize UI Context Menu items. See GlideMenu.</td>
</tr>
<tr>
<td>GlideUser</td>
<td>Use this class to get session information about the current user and current user roles. See GlideUser.</td>
</tr>
</tbody>
</table>

Glide stack

Glide is an extensible Web 2.0 development platform written in Java that facilitates rapid development of forms-based workflow applications (work orders, trouble ticketing, and project management, for example).

User interface stack technology map

<table>
<thead>
<tr>

</tr>
<tr>
<td>Persistence</td>
<td></td>
<td>• Persistence means any store&lt;br&gt;◦ RDBMS&lt;br&gt;◦ LDAP&lt;br&gt;◦ File system&lt;br&gt;• Uniform access regardless of store type&lt;br&gt;• Provides QUID and meta-data capabilities&lt;br&gt;• Interfaces presented to callers&lt;br&gt;◦ RecordSet&lt;br&gt;◦ TableDescriptor&lt;br&gt;◦ ElementDescriptor</td>
</tr>
</tbody>
</table>
Execution order of scripts and engines

Scripts, assignment rules, business rules, workflows, escalations, and engines all take effect in relation to a database operation, such as insert or update. In many cases, the order of these events is important.

⚠️ Note: Client-based code that executes in the browser, using Ajax or running as JavaScript, will always execute before the form submission to the server.

The order of execution is as follows:

1. **Before business rules**: Scripts configured to execute before the database operation with an order less than 1000.

2. **Before engines**: The following are not executed in any specific order:
   - Approval engine (for task and sys_approval_approver tables)
   - Assignment rules engine (for task tables)
   - Data policy engine
• Escalation engine
• Field normalization engine
• Role engine - keeps role changes in sync with sys_user_has_role table (for sys_user, sys_user_group, sys_user_grmember, and sys_user_role tables)
• Execution plan engine (for task tables)
• Update version engine - creates version entry when sys_update_xml entry is written (for sys_update_xml table)
• Workflow engine (for default workflows)

3. Before business rules: Scripts configured to execute before the database operation with an order greater than or equal to 1000.

4. The database operation (insert, update, delete).

5. After business rules: Scripts configured to execute after the database operation with an order less than 1000.

6. After engines. The following are not executed in any specific order:
   • Label engine
   • Listener engine
   • Table notifications engine
   • Role engine - keeps role changes in sync with sys_user_has_role table (for sys_user, sys_user_group, sys_user_grmember and sys_user_role tables)
   • Text indexing engine
   • Update sync engine
   • Data lookup engine inserts or updates
   • Workflow engine (for deferred workflows)
   • Trigger engine (for all Flow Designer flows)

7. Email notifications. The following are executed based on the weight of the notification record:
   • Notifications sent on an insert, update, or delete
   • Event-based notifications

8. After business rules. Scripts configured to execute after the database operation with an order greater than or equal to 1000.

**Script evaluation of fields by data type**

Script fields evaluate data based on the field type of the input.
### Evaluation of fields by data types

<table>
<thead>
<tr>
<th>Type</th>
<th>Evaluates to in script</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>The string</td>
<td>&quot;dog&quot; &gt; &quot;dog&quot;</td>
</tr>
<tr>
<td>Decimal</td>
<td>A number with up to two decimal points</td>
<td>12.34 &gt; 12.34</td>
</tr>
<tr>
<td>Integer</td>
<td>A number with zero decimal points</td>
<td>12 &gt; 12</td>
</tr>
<tr>
<td>True / False</td>
<td>true or false</td>
<td>☑️ &gt; true</td>
</tr>
<tr>
<td>Date</td>
<td>A date formatted as yyyy-mm-dd</td>
<td>2008-11-04</td>
</tr>
<tr>
<td>Date-time</td>
<td>A day and time formatted as yyyy-mm-dd hh:mm:ss</td>
<td>2008-11-04 06:46:20</td>
</tr>
</tbody>
</table>
| Duration     | A date that is equal to January 1st 1970 00:00:00 + the amount of time of the duration being stored | Days 00 Hours 00:00:00 > "1970-01-01 00:00:00"  
Days 1 Hours 02:03:04 > "1970-01-02 02:03:04" |
### Evaluation of fields by data types (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Evaluates to in script</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Choice</td>
<td>Returns the contents of the value field for the <code>sys_choice</code> record associated with that choice. See: Choice List for more information on returning the value associated with a particular item in a choice list.</td>
<td><code>Incident state: New</code> &gt; &quot;2&quot; (Note that this value is a string)</td>
</tr>
<tr>
<td>Journal</td>
<td>Returns a string of all entries made to that journal field. See Journal Fields for scripting of journal type fields</td>
<td>The web server is down &gt; The web server is down</td>
</tr>
</tbody>
</table>

**Note:** This date corresponds to the system time zone. If a different user time zone has been specified, the date and time value may appear different for that user.
## Evaluation of fields by data types (continued)

<table>
<thead>
<tr>
<th>Type</th>
<th>Evaluates to in script</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reference</td>
<td>Returns the sys_id of the record that is referenced</td>
<td><img src="http://www.service-now.com" alt="Database" /> &gt; &quot;287ee6fe9fe198100ada7950db1b73&quot;</td>
</tr>
<tr>
<td>Image</td>
<td>Returns the path to the image</td>
<td><img src="http://images/icons/image_name.gif" alt="Image" /> &gt; images/icons/image_name.gif</td>
</tr>
<tr>
<td>URL</td>
<td>Returns a string</td>
<td><img src="http://www.service-now.com" alt="URL" /> &gt; &quot;<a href="http://www.service-now.com">http://www.service-now.com</a>&quot;</td>
</tr>
<tr>
<td>Glide Lists</td>
<td>Returns a string of comma-separated Sys IDs</td>
<td><img src="http://example.com" alt="Watch list" /> &gt; 5137153cc611227c000bd1bd8cd2007d14f049a9fe19810</td>
</tr>
</tbody>
</table>

## Scripting alert, info, and error messages

You can send messages to customers as alerts, informative messages, or error messages.

### Business rule and other general use scripts

<table>
<thead>
<tr>
<th>Script</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>current.field_name.setError(&quot;Hello World&quot;);</code></td>
<td>Will put &quot;Hello World&quot; below the specified field.</td>
</tr>
<tr>
<td><code>gs.addInfoMessage(&quot;Hello World&quot;);</code></td>
<td>Will put &quot;Hello World&quot; on the top of the screen.</td>
</tr>
<tr>
<td><code>gs.print(&quot;Hello World&quot;);</code></td>
<td>Will write to the text log on the file system but not to the sys_log table in the database.</td>
</tr>
<tr>
<td><code>gs.log(&quot;Hello World&quot;);</code></td>
<td>Will write to the database and the log file.</td>
</tr>
</tbody>
</table>

**Note:** Too much of this can adversely affect performance.

### Important: The methods in this table are only for use in client scripts.
Client side scripts

<table>
<thead>
<tr>
<th>Script</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>alert(&quot;Hello World&quot;);</code></td>
<td>Will pop up a window with &quot;Hello World&quot; and an 'OK' button.</td>
</tr>
<tr>
<td><code>confirm(&quot;Hello World&quot;);</code></td>
<td>Will pop up a window with &quot;Hello World?&quot; and a 'Ok' and 'Cancel' buttons.</td>
</tr>
<tr>
<td><code>g_form.showFieldMsg(&quot;field_name&quot;, &quot;Hello World&quot;, &quot;error&quot;);</code></td>
<td>Puts &quot;Hello World&quot; in an error message below the specified field.</td>
</tr>
<tr>
<td><code>g_form.hideFieldMsg(&quot;field_name&quot;);</code></td>
<td>Hides an error message that is visible under the specified field.</td>
</tr>
</tbody>
</table>

It is also possible to add other custom messages to your forms if necessary using client scripting.

The text size of info and error messages at the top of the screen is customizable. Two properties control this. If you configured your forms, you may need to add these properties.

Error and alert text size properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>css.outputmsg.info.text.font-size</code></td>
<td>Sets the size for info messages. Default is 11pt.</td>
</tr>
<tr>
<td><code>css.outputmsg.error.text.font-size</code></td>
<td>Sets the size for error messages. Default is 11pt.</td>
</tr>
</tbody>
</table>

Using regular expressions in scripts

JavaScript regular expressions automatically use an enhanced regex engine, which provides improved performance and supports all behaviors of standard regular expressions as defined by Mozilla JavaScript. The enhanced regex engine supports using Java syntax in regular expressions.

The `SNC.Regex` API is not available for scoped applications. For scoped applications, remove the `SNC.Regex` API and use standard JavaScript regular expressions.

For more information on JavaScript regular expressions, see the Mozilla JavaScript documentation on regular expressions and `RegExp`. 
Using Java syntax in JavaScript regular expressions

The enhanced regex engine includes an additional flag to allow Java syntax to be used in JavaScript regular expressions.

Regular expressions with the additional flag work in all places that expect a regular expression, such as `String.prototype.split` and `String.prototype.replace`. To use Java syntax in a regular expression, use the Java inline flag `j`, for example:

```
/(?ims)ex(am)ple/j
```

### Extended regular expression flags

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>j</td>
<td>Defines a regular expression that executes using the Java regular expression engine. It can be used to access Java-only features of regular expressions (such as look behind, negative look behind) or to use Java regular expressions without translating them into JavaScript regular expressions. For example: <code>var regex = /ex(am)ple/j;</code></td>
</tr>
</tbody>
</table>

Convert SNC Regex expressions to enhanced regex expressions

When you upgrade to Eureka Patch 5 or later releases, you should convert scripts that use the `SNC.Regex` API to use regular JavaScript expressions.

**Procedure**

1. From the original expression, such as: `SNC.Regex("/expr/is")`, create a new regular expression object using the pattern with the slashes stripped.

   **Example**
   ```
   new RegExp('expr');
   ```

2. Move the `SNC.Regex` flags to the start of the expression using Java’s inline flag special construct.

   **Example**
   ```
   new RegExp('(?is)expr');
   ```

3. Add the `j` flag to the `RegExp` to tell the engine to treat the expression as a Java expression.

   **Note:** If you know that the script being converted does not use Java syntax, it is not necessary to use the `j` flag.
Example

```
new RegExp('(?is)expr', 'j');
```

4. Add the `g` flag to handle multiple matches or a global replace.

Example

```
new RegExp('(?is)expr', 'jg');
```

Example:
Using SNC.Regex

```
var r = new SNC.Regex('/world/');
var str = 'helloworld';
var replaced = r.replaceAll(str, 'there');
// replaced == 'hellothere'
```

Using a JavaScript regular expression

```
var r = new RegExp('world', 'jg');
var str = 'helloworld';
var replaced = str.replace(r, 'there');
// replaced == 'hellothere'
```

**JavaScript syntax editor**

The syntax editor provides support for editing JavaScript scripts.

The syntax editor has these features.

- JavaScript syntax coloring, indentation, line numbers, and automatic creation of closing braces and quotes
- JavaScript support
- Linting using the ESLint utility

ℹ️ Note: Modify or view default linting configurations by accessing the `glide.ui.syntax_editor.linter.eslint_config` property in the System Property [sys_properties] table. See Available system properties for more information.

- Context menu for script includes, API, and tables
- Script macros for common code shortcuts

This feature requires the Syntax Editor (com.glide.syntax_editor) plugin.
Script macro maintenance

Administrators can define new script macros or modify existing script macros.

Before you begin
Role required: admin

About this task
Script macros provide shortcuts for typing commonly used code. Several script macros are available by default. Administrators can define new or modify existing script macros.

Procedure
1. Navigate to **System Definition > Syntax Editor Macros**.
2. Click **New** or select the macro to edit.
3. Define the macro details with the fields listed in the table below.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Macro keyword text users type to insert macro text.</td>
</tr>
<tr>
<td>Comments</td>
<td>Description of the macro. This text appears when the user types help.</td>
</tr>
<tr>
<td>Text</td>
<td>Full macro text that replaces the name in the editor.</td>
</tr>
</tbody>
</table>
Syntax editor plugin

Enable the syntax editor plugin to use the syntax editor. The syntax editor enables the following features for all script fields:

- JavaScript syntax coloring, indentation, line numbers, and automatic creation of closing braces and quotes
- Code editing functions
- Code syntax checking
- Script macros for common code shortcuts

JavaScript syntax editor

The syntax editor can be disabled or enabled by modifying the `glide.ui.javascript_editor` property in the `sys_properties.list`. In addition, administrators can configure the syntax editor to show error and warning indicators next to a line of code that contains an error by modifying the `glide.ui.syntax_editor.show_warnings_errors` property. For information on the `sys_properties.list`, refer to Available system properties.

**Note:** Administrators can disable or enable the syntax editor for all users, regardless of user preference.

Searching for errors by line

To locate the exact position of the error in a large script, click the Go to line icon. This feature is particularly useful when you are encounter a syntax error in a log file rather than in the ServiceNow record itself. In this case, you can navigate to the record and search for errors by line number. In the dialog box that appears, enter the line number of an error, and then click OK. Your view moves to the site of the error, and the cursor marks the correct line and column.
Note: For this feature to function, you must disable the Syntax Editor.

Navigate to a line number
When the syntax editor is disabled, users can navigate to a specific line in the code using the Go to line icon (î).

Procedure
1. Click the Go to line icon (î).

   Note: This icon is not available when the editor is enabled.

2. Enter a number in the field and then press Enter.

Syntax editor JavaScript support
The syntax editor provides editing functions to support editing JavaScript scripts.

JavaScript editing functions

<table>

**JavaScript editing tips**

- To fold a code block, click the minus sign beside the first line of the block. The minus sign only appears beside blocks that can be folded. To unfold the code block, click the plus sign.
- To insert a fixed space anywhere in your code, press Tab.
- To indent a single line of code, click in the leading white space of the line and then press Tab.
- To indent one or more lines of code, select the code and then press Tab. To decrease the indentation, press Shift + Tab.
- To remove one tab from the start of a line of code, click in the line and press Shift + Tab.

**JavaScript resources**

Scripts use ECMA 262 standard JavaScript. Helpful resources include:

- Mozilla: [http://developer.mozilla.org/en/docs/Core_JavaScript_1.5_Reference](http://developer.mozilla.org/en/docs/Core_JavaScript_1.5_Reference)
- History and overview: [http://javascript.crockford.com/survey.html](http://javascript.crockford.com/survey.html)

**Context menu**

Enable the context menu for script includes, Glide APIs, and tables in the JavaScript editor.
With the context menu options, your users can navigate to:

- Script include definitions
- Glide API documentation
- System and custom table definitions and data

In the syntax editor, bold font is used for tokens that have a context menu. Right-click the token to view context menu options. If you use a Mac, you can use the Command-click shortcut.

### Context menu options

<table>
<thead>
<tr>
<th>Token type</th>
<th>Context menu option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Script include</td>
<td>Open Definition</td>
<td>Definition of the script include in a new window.</td>
</tr>
<tr>
<td></td>
<td>Find References</td>
<td>List of files referencing the script include.</td>
</tr>
<tr>
<td>Glide API</td>
<td>Show Documentation</td>
<td>Documentation page of the Glide API.</td>
</tr>
<tr>
<td>Table</td>
<td>Show Definition</td>
<td>Definition of the system or custom table in a new window.</td>
</tr>
</tbody>
</table>

**Note:**
- To view the preview of the file, click the preview script icon 🔄.
  - To open the file in a new window, click **Open File**.
- To view all files that reference the script include, click **Show All Files**.
Context menu options (continued)

<table>
<thead>
<tr>
<th>Token type</th>
<th>Context menu option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Show Data</td>
<td>Records in the table that are based on the role of the current user.</td>
</tr>
</tbody>
</table>

Enable or disable the context menu in the script editor using the `glide.ui.syntax_editor.context_menu` property in the System Property [sys_properties] table. See Available system properties for more information.

⚠️ Note: Context menu options can be accessed only if the browser supports SharedWorker. For example, Google Chrome and Mozilla Firefox.

Syntax editor macros

Script macros provide shortcuts for typing commonly used code. To insert macro text into a script field, enter the macro keyword followed by the Tab.

**vargr**

- **Description**: Inserts a standard `GlideRecord` query for a single value.
- **Output**:

```javascript
var now_GR = new GlideRecord('');
gr.addQuery("name", "value");
gr.query();
if (gr.next()) {
}
```

**vargror**

- **Description**: Inserts a `GlideRecord` query for two values with an OR condition.
- **Output**:

```javascript
var now_GR = new GlideRecord('');

var qc = gr.addQuery('field', 'value1');
qc.addOrCondition('field', 'value2');
```
gr.query();
while (gr.next()) {
}

for

- **Description**: Inserts a standard recursive loop with an array.
- **Output**:

```javascript
for (var i=0; i< myArray.length; i++) {
    //myArray[i];
}
```

info

- **Description**: Inserts a GlideSystem information message.
- **Output**:

```javascript
gs.addInfoMessage('"');
```

method

- **Description**: Inserts a blank JavaScript function template.
- **Output**:

```javascript
/*_________________________________________________________________
 * Description:
 * Parameters:
 * Returns:
 *________________________________________________________________*/
 : function() {
 },
```

doc

- **Description**: Inserts a comment block for describing a function or parameters.
- **Output**:
Script syntax error checking

All script fields provide controls for checking the syntax for errors and for locating the error easily when one occurs. The script editor places the cursor at the site of a syntax error and lets you search for errors in scripts by line number.

The script editor notifies you of syntax errors in your scripts in the following situations.

- Save a new record or update an existing record. A banner appears at the bottom of the editor showing the location of the first error (line number and column number), and the cursor appears at the site of the error. Warnings presented at Save or Update show only one error at a time.
Click the syntax checking icon before saving or updating a record. A banner appears at the bottom of the editor showing the location of all errors in the script, and the cursor appears at the site of the first error.

**Script syntax error**

```
Error:
Problem at line 23 character 15: Missing `}` before `continue`.
continue;
Problem at line 25 character 52: Expected `)` and instead saw `:`
item.setAttribute(name, gr.getValue(name));
Problem at line 25 character 53: Missing `:`
item.setAttribute(name, gr.getValue(name));
```

**Syntax editor keyboard shortcuts and actions**

The syntax editor offers keyboard shortcuts and actions to assist in writing code.

<table>
<thead>
<tr>
<th>Keyboard shortcut or action</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Write code</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Scripting assistance</td>

<td>Format code</td>
<td>Formats the selected lines to improve readability.</td>
<td></td>
</tr>
</tbody>
</table>
| • **Windows**: Control+Shift+B  
  • **Mac**: Command+Shift+B |             |         |
| Toggle comment             | Adds or removes the comment characters // from the selected lines. | |
| • **Windows**: Control+/  
  • **Mac**: Command+/ |             |         |
| Insert macro text          | Inserts macro text at the current position. | |
  1. In the **Script** field, type the macro keyword text. For example `help`.  
  2. Press Tab. |
| Search                     |             |         |
| Start search               | Highlights all occurrences of a search term in the script field and locates the first occurrence. | |
| • **Windows**: Control+F  
  • **Mac**: Command+F | You can create regular expressions by enclosing the search terms between slash characters / . For example, the search term `/a(3)/` locates the string `aaa`. | |
| Find next                  | Locates the next occurrence of the current search term in the script field. Use **Start Searching** to change the current search term. | |
| • **Windows**: Control+G  
  • **Mac**: Command+G |             |         |
| Find previous              | Locates the previous occurrence of the current search term in the script field. Use | |
### Syntax editor keyboard shortcuts and actions for writing code (continued)

<table>
<thead>
<tr>
<th>Keyboard shortcut or action</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
</table>
| • **Windows**: Control + Shift + G  
  • **Mac**: Command + Shift + G | **Start Searching** to change the current search term. |        |

Replace

| • **Windows**: Control+E  
  • **Mac**: Command+E | | |
|-----------------------|----------------------------------------------------------------|---------|
| Replace all
  • **Windows**: Control++;  
  • **Mac**: Command++; | Replaces all occurrences of a text string in the script field. |        |

Help

| • **Windows**: Control+H  
  • **Mac**: Command+H | | |
|-----------------------|----------------------------------------------------------------|---------|
| Show description
  • **Windows**: Control+J  
  • **Mac**: Command+J | Displays API documentation for the scripting element at the cursor’s current location. |        |

**Show macros**

1. In the **Script** field, type `help.`
2. Press Tab.

Displays the list of available syntax editor macros as text within the script field.

---

**HTML syntax editor**

The HTML syntax editor provides support for editing HTML and Jelly scripts and defines what's rendered when the page is displayed. The HTML syntax editor can contain either static XHTML or dynamically generated content defined as Jelly, and can call script includes and UI Macros.

The syntax editor has these features.
• HTML and Jelly script support
• HTML and Jelly syntax coloring, indentation, line numbers, and automatic creation of closing braces and quotes
• Auto-suggestions for HTML and Jelly tags

⚠️ Note: The keyboard shortcut is Ctrl+Space.
• Script macros for common code shortcuts

### HTML syntax editor

```xml
<%=jelly trim="true" xmlns=":jellycore" xmlns=":glide" xmlns:i=":null" xmlns:m=":null">
  <input type="hidden" name="selection_result" id="selection_result" value=""/>
  <input type="hidden" name="my_sys_id" id="my_sys_id" value="${cmp.getProperty('sys_id')}"/>
  <div style="text-align:center;">
    <div>${cmp.getMessage('Are you sure you want to close this interaction?')}</div>
  </div>

<%=/*
  comments the selected code.
*/%>

<%=//
  replaces the next occurrence of a text string in the script field.
  1. Click the Replace icon ( ), then enter the string to replace, and press Enter. You can use regular expressions enclosed in slashes to define the string to replace. For example, the term /a{3}/ locates aaa.
  2. Enter the replacement string and press Enter.

<%=/jelly%>
```

### HTML and Jelly editing functions

<table>
<thead>
<tr>
<th>Icon</th>
<th>Keyboard shortcut</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

### Editing tips

- To insert a fixed space anywhere in your code, press Tab.
- To indent a single line of code, click in the leading white space of the line and then press Tab.
• To indent one or more lines of code, select the code and then press Tab. To decrease the indentation, press Shift+Tab.

• To remove one tab from the start of a line of code, click in the line and press Shift+Tab.

**Code editor**

The code editor provides support to use programming language services in a text editor and is used in scripts.

The code editor has these features for the supported language services and scripts:

• Syntax coloring, indentation, line numbers, and automatic creation of closing braces and quotes

• Auto-suggestions and auto-completions

**Editing tips**

• To insert a fixed space anywhere in your code, press Tab.

• To indent a single line of code, click in the leading white space of the line and then press Tab.

• To indent one or more lines of code, select the code and then press Tab. To decrease the indentation, press Shift+Tab.

• To remove one tab from the start of a line of code, click in the line and press Shift+Tab.

• To declare variables, use the `var` keyword so that they remain within the proper JavaScript scope.

**Server-side scripting**

Server scripts run on the server or database. They can change the appearance or behavior of ServiceNow or run as business rules when records and tables are accessed or modified.
Server-side Glide APIs (Application Programming Interfaces) provide classes and methods that you can use in scripts to perform server-side tasks.

**Immediately invoked function expressions**

The system uses immediately invoked function expressions when a script runs in a single context, such as in a transform map script. Functions that run from multiple contexts use Script includes instead.

By enclosing a script in an immediately invoked function expression, you can:

- Ensure that the script does not impact other areas of the product, such as by overwriting global variables.
- Pass useful variables or objects as parameters.
- Identify function names in stack traces.
- Eliminate having to make separate function calls.

An immediately invoked function expression follows this format:

```javascript
(function functionName(parameter){
    //The script you want to run
})('value');//Note the parenthesis indicating this function should run.
```

You can declare functions within the immediately invoked function expression. These inner functions are accessible only from within the immediately invoked function expression.

```javascript
(function functionName(parameter){
    function helperFunction(parameter){//return some value}
    var value = helperFunction(parameter);//Valid function call.
    //perform any other script actions
})('value');

var value2 = helperFunction(parameter);//Invalid. This function is not accessible from outside the self-executing function.
```

**Glide Server APIs**

ServiceNow provides APIs for the Glide Server.
GlideAggregate

The GlideAggregate class is an extension of GlideRecord and allows database aggregation (COUNT, SUM, MIN, MAX, AVG) queries to be done. This can be helpful in creating customized reports or in calculations for calculated fields.

ℹ️ Note: This functionality requires a knowledge of JavaScript.

For additional information, refer to GlideAggregate API.

GlideAggregate examples

GlideAggregate is an extension of GlideRecord and its use is probably best shown through a series of examples.

ℹ️ Note: This functionality requires a knowledge of JavaScript.

Here is an example that simply gets a count of the number of records in a table:

```javascript
var count = new GlideAggregate('incident');
count.addAggregate('COUNT');
count.query();
var incidents = 0;
if(count.next())
    incidents = count.getAggregate('COUNT');
```

There is no query associated with the preceding example. If you want to get a count of the incidents that were open, simply add a query as is done with GlideRecord. Here is an example to get a count of the number of active incidents.

```javascript
var count = new GlideAggregate('incident');
count.addQuery('active','true');
count.addAggregate('COUNT');
count.query();
var incidents = 0;
if(count.next())
    incidents = count.getAggregate('COUNT');
```

To get a count of all the open incidents by category the code is:

```javascript
var count = new GlideAggregate('incident');
count.addQuery('active','true');
count.addAggregate('COUNT','category');
count.query();
while(count.next())
    var category = count.category;
```
```javascript
var categoryCount = count.getAggregate('COUNT','category');
gs.log("The are currently "+ categoryCount +" incidents with a category of "+ category);
```

The output is:

```javascript
*** Script: The are currently 1.0 incidents with a category of Data
*** Script: The are currently 11.0 incidents with a category of Enhancement
*** Script: The are currently 1.0 incidents with a category of Implementation
*** Script: The are currently 197.0 incidents with a category of inquiry
*** Script: The are currently 13.0 incidents with a category of Issue
*** Script: The are currently 47.0 incidents with a category of request
```

The following is an example that uses multiple aggregations to see how many times records have been modified using the MIN, MAX, and AVG values.

```javascript
var count = new GlideAggregate('incident');
count.addAggregate('MIN','sys_mod_count');
count.addAggregate('MAX','sys_mod_count');
count.addAggregate('AVG','sys_mod_count');
count.groupBy('category');
count.query();
while(count.next()){
  var min = count.getAggregate('MIN','sys_mod_count');
  var max = count.getAggregate('MAX','sys_mod_count');
  var avg = count.getAggregate('AVG','sys_mod_count');
  var category = count.category.getDisplayValue();
  gs.log(category +" Update counts: MIN = "+ min +" MAX = "+ max +" AVG = "+ avg);
}
```

The output is:

```javascript
*** Script: Data Import Update counts: MIN = 4.0 MAX = 21.0 AVG = 9.3333
*** Script: Enhancement Update counts: MIN = 1.0 MAX = 44.0 AVG = 9.6711
*** Script: Implementation Update counts: MIN = 4.0 MAX = 8.0 AVG = 6.0
*** Script: inquiry Update counts: MIN = 0.0 MAX = 60.0 AVG = 5.9715
*** Script: Inquiry / Help Update counts: MIN = 1.0 MAX = 3.0 AVG = 2.0
*** Script: Issue Update counts: MIN = 0.0 MAX = 63.0 AVG = 14.9459
*** Script: Monitor Update counts: MIN = 0.0 MAX = 63.0 AVG = 3.6561
*** Script: request Update counts: MIN = 0.0 MAX = 53.0 AVG = 5.0987
```

The following is a more complex example that shows how to compare activity from one month to the next.

```javascript
var agg = new GlideAggregate('incident');
agg.addAggregate('count','category');
agg.orderByAggregate('count','category');
agg.orderBy('category');
```
agg.addQuery('opened_at','>=','javascript:gs.monthsAgoStart(2)');
agg.addQuery('opened_at','<=','javascript:gs.monthsAgoEnd(2)');
agg.query();
while(agg.next()){  
    var category = agg.category;
    var count = agg.getAggregate('count','category');
    var query = agg.getQuery();
    var agg2 = new GlideAggregate('incident');
    agg2.addAggregate('count','category');
    agg2.orderByAggregate('count','category');
    agg2.orderBy('category');
    agg2.addQuery('opened_at','>=','javascript:gs.monthsAgoStart(3)');
    agg2.addQuery('opened_at','<=','javascript:gs.monthsAgoEnd(3)');
    agg2.addEncodedQuery(query);
    agg2.query();
    var last ="";
    while(agg2.next()){  
        last = agg2.getAggregate('count','category');
    }
    gs.log(category +": Last month:"+ count +" Previous Month:"+ last);
}

The output is:

*** Script: Monitor: Last month:6866.0 Previous Month:4468.0
*** Script: inquiry: Last month:142.0 Previous Month:177.0
*** Script: request: Last month:105.0 Previous Month:26.0
*** Script: Issue: Last month:8.0 Previous Month:7.0
*** Script: Enhancement: Last month:5.0 Previous Month:5.0
*** Script: Implementation: Last month:1.0 Previous Month:0

The following is an example to obtain distinct count of a field on a group query.

var agg = new GlideAggregate('incident');
agg.addAggregate('count');
agg.addAggregate('count(distinct','category');
agg.addQuery('opened_at', '>=', 'javascript:gs.monthsAgoStart(2)');
agg.addQuery('opened_at', '<=', 'javascript:gs.monthsAgoEnd(2)');
//
agg.groupBy('priority');
agg.query();
while (agg.next()) {  
    // Expected count of incidents and count of categories within each priority value (group)
    gs.info('Incidents in priority ' + agg.priority + ' - ' + agg.getAggregate('count') +

You can implement the SUM aggregate with or without the use of the `groupBy()` method. If you do not use the `groupBy()` method, the result of the SUM is the cumulative value for each different value of the field for which you request the SUM. For example, if you SUM the `total_cost` field in the Fixed Asset table, and the Fixed Asset table contains 12 total records:

- Three records with a `total_cost` of $12
- Four records with a `total_cost` of $10
- Five records with a `total_cost` of $5

When you SUM the record set, the `getAggregate()` method returns three different sums: $36, $40, and $25.

The following code illustrates implementing the SUM aggregate without using the `groupBy()` method:

```javascript
var totalCostSum = new GlideAggregate('fixed_asset');
totalCostSum.addAggregate('SUM', 'total_cost');
totalCostSum.query();

while (totalCostSum.next()) {
    var allTotalCost = 0;
    allTotalCost = totalCostSum.getAggregate('SUM', 'total_cost');
    aTotalCost = totalCostSum.getValue('total_cost');
    gs.print('Unique field value: ' + aTotalCost + ', SUM = ' + allTotalCost + ', ' + allTotalCost/aTotalCost + ' records');
}
```

The output for this example is:

- **Script**: Unique field value: 12, SUM = 36, 3 records
- **Script**: Unique field value: 10, SUM = 40, 4 records
- **Script**: Unique field value: 5, SUM = 25, 5 records

Using the same data points as the prior example, if you use the `groupBy()` method, the SUM aggregate returns the sum of all values for the specified field.
The following example illustrates implementing the SUM aggregate using the `groupBy()` method:

```javascript
var totalCostSum = new GlideAggregate('fixed_asset');
totalCostSum.addAggregate('SUM', 'total_cost');
totalCostSum.groupBy('total_cost');
totalCostSum.query();
if(totalCostSum.next()){ // in case there is no result
    var allTotalCost = 0;
    allTotalCost = totalCostSum.getAggregate('SUM', 'total_cost');
    gs.print('SUM of total_cost: = ' + allTotalCost);
}
```

The output for this example is:

```plaintext
*** Script: SUM of total_cost: 101
```

**GlideRecord**

`GlideRecord` is a special Java class (`GlideRecord.java`) that can be used in JavaScript exactly as if it was a native JavaScript class.

**GlideRecord:**
- is used for database operations instead of writing SQL queries.
- is an object that contains zero or more records from one table. Another way to say this is that a GlideRecord is an ordered list.

A GlideRecord contains both records (rows) and fields (columns). The field names are the same as the underlying database column names. For additional information, refer to [GlideRecord - Scoped](#).

ℹ️ **Note:** Use of `gs.sql()` scripting syntax was discontinued in Geneva. Use standard GlideRecord syntax in its place.

**Using GlideRecordSecure**

`GlideRecordSecure` is a class inherited from `GlideRecord` that performs the same functions as `GlideRecord`, and also enforces ACLs.

**Non-writable fields**

Be aware that, when using `GlideRecordSecure`, non-writable fields are set to NULL when trying to write to the database. By default, `canCreate()` on the column is replaced with `canWrite()` on the column. If that returns false, the column value is set to NULL.
Checking for NULL values
If an element cannot be read because an ACL restricts access, a NULL value is created in memory for that record. With GlideRecord, you must explicitly check for any ACLs that might restrict read access to the record. To do so, an if statement such as the following is required to check if the record can be read:

if ( !grs.canRead() ) continue;

With GlideRecordSecure, you do not need to explicitly check for read access using canRead(). Instead, you can use next() by itself to move to the next record. The following example provides a comparison between GlideRecord and GlideRecordSecure.

```javascript
var count  = 0;
var now_GR  = new GlideRecord('mytable');
now_GR. query();
while (now_GR. next()) {
    if (!now_GR. canRead()) continue;
    if (!now_GR. canWrite()) continue;
    if (!now_GR. val. canRead() || !now_GR. val. canWrite())
        now_GR. val = null;
    else
        now_GR. val = "val-" + now_GR. id;
    if (now_GR. update())
        count ++;
}

var count  = 0;
var grs  = new GlideRecordSecure('mytable');
grs. query();
while (grs. next()) {
    grs. val = "val-" + grs. id;
    if (grs. update())
        count ++;
}
```

Examples
These are two simple examples using GlideRecordSecure.

```javascript
var att  = new GlideRecordSecure ('sys_attachment');
att. get('$[sys_attachment.sys_id]');
var sm  = GlideSecurityManager.get();
var checkMe  = 'record/sys_attachment/delete';
var canDelete  = sm.hasRightsTo(checkMe,att);
```
gs.log('canDelete: ' + canDelete);
canDelete;

var grs = new GlideRecordSecure('task_ci');
grs.addQuery();
grs.query();
var count = grs.getRowCount();
if (count > 0) {
    var allocation = parseInt(10000/count) / 100;
    while (grs.next()) {
        grs.u_allocation = allocation;
        grs.update();
    }
}

GlideSystem

The GlideSystem API provides methods for retrieving information.
The GlideSystem (referred to by the variable name 'gs' in business rules) provides a number of convenient methods to get information about the system, the current logged in user, etc. For example, the method addInfoMessage() permits communication with the user.

    gs.addInfoMessage('Email address added for notification');

Many of the GlideSystem methods facilitate the easy inclusion of dates in query ranges and are most often used in filters and reporting.

For additional information, see GlideSystem.

GlideDateTime

The GlideDateTime class provides methods for performing operations on GlideDateTime objects, such as instantiating GlideDateTime objects or working with glide_date_time fields.

In addition to the instantiation methods described below, a GlideDateTime object can be instantiated from a glide_date_time field using the getGlideObject() method (for example, var gdt =
    gr.my_datetime_field.getGlideObject();).

Some methods use the Java Virtual Machine time zone when retrieving or modifying a date and time value. Using these methods may result in unexpected behavior. Use equivalent local time and UTC methods whenever possible.

For additional information, refer to GlideDateTime.
GlideDate and GlideDateTime examples

The GlideDate and GlideDateTime APIs are used to manipulate date and time values.

Note: This functionality requires a knowledge of JavaScript.

For additional information, refer to GlideDate API and GlideDateTime API.

You can create a GlideDateTime object from a GlideDate object by passing in the GlideDate object as a parameter to the GlideDateTime constructor. By default, the GlideDateTime object is expressed in the internal format, yyyy-MM-dd HH:mm:ss and the system time zone UTC.

```javascript
var gDate = new GlideDate();
gDate.setValue('2015-01-01');
gs.info(gDate);

var gDT = new GlideDateTime(gDate);
gs.info(gDT);
```

Output:

```
2015-01-01
2015-01-01 00:00:00
```

Set a duration field value in script

Examples of JavaScript that can be used to set the value of a duration field.

Note: Negative duration values are not supported.

Using the GlideDateTime.subtract() method

The `subtract(GlideDateTime start, GlideDateTime end)` method in GlideDateTime enables you to set the duration value using a given start date/time and end date/time. An example on how to set the duration for the time a task was opened is:

```javascript
var duration = GlideDateTime.subtract(start, end);
```

If you want to work with the value returned as a number to use in date or duration arithmetic, convert the return to milliseconds:

```javascript
var time = GlideDateTime.subtract(start,end).getNumericValue();
```

If you want to set a duration to the amount of time between some event and the current date/time:
The time values presented to `GlideDateTime.subtract` are expected to be in the user's time zone and in the user's format.

### Setting a default value of a duration field

Setting the default value for a duration field is similar to the method used in the previous topic.

### Setting the duration field value in a client script

This script sets a `duration_field` value in a client script. Replace `duration_field` with the field name from your instance.

```javascript
g_form.setValue('<duration_field>','11 01:02:03');
```

### Calculating and setting a duration using a client script

Here is an example of how to return a value and populate it using a client script.

Create an `onChange` client script that includes the following code. You can modify this script if you need the calculation to happen in an `onLoad` script or some other way.

```javascript
function onChange(control, oldValue, newValue, isLoading){
    var strt = g_form.getValue('<start_field>');
    var end = g_form.getValue('<end_field>');
    var ajax = new GlideAjax('AjaxDurCalc');
    ajax.addParam('sysparm_name','durCalc');
    ajax.addParam('sysparm_strt',strt);
    ajax.addParam('sysparm_end',end);
    ajax/XMLWait();
    var answer = ajax.getAnswer();
    g_form.setValue('<duration_field>', answer);
}
```

Create a system script include file called `AjaxDurCalc` that handles the request. It may be reused for other functions as well.

```javascript
var AjaxDurCalc = Class.create();
AjaxDurCalc.prototype = Object.extendsObject(AbstractAjaxProcessor,{
    durCalc:function(){return
        GlideDuration.subtract(this.getParameter('sysparm_strt'),this.getParameter('sysparm_end'));
    };
});
```

### Changing the duration field value

If you manipulate a duration value with addition/subtraction of some amount of time, use the functions that allow you to get and set the numeric value of ...
the duration. A unit of measure for a duration numeric value is milliseconds. The following is an example that adds 11 seconds to the duration field in the current record.

```javascript
var timems = current.duration.dateNumericValue();
timems = timems + 11*1000;
current.duration.setDateNumericValue(timems);
```

**Formatting the Resolve Time**

To format the **Resolve Time** or the **Business Resolve Time** fields as durations, which displays them as a duration instead of a large integer, add the following attribute to those fields:

```
format=glide_duration
```

Modify the dictionary entry for the field and add the attribute. If there is an existing attribute, separate multiple attributes with commas.

**Setting the maximum unit of measurement**

The `max_unit` dictionary attribute defines the maximum unit of time used in a duration. For example, if `max_unit=minutes`, a duration of 3 hours 5 minutes 15 seconds appears as 185 minutes 15 seconds. To set the maximum unit of duration measurement, add the following dictionary attribute to the `duration` field:

```
max_unit=<unit>
```

**Business rules**

A business rule is a server-side script that runs when a record is displayed, inserted, updated, or deleted, or when a table is queried.

Use business rules to accomplish tasks like automatically changing values in form fields when certain conditions are met, or to create events for email notifications and script actions.

**Note:** Business rules can make use of scripts to take actions on records in the database. However, there are several other scripting options available on the platform, such as client scripts and UI actions.

**How business rules work**

To configure business rules, you first need to determine when the business rule should run and what action it should take.
When business rules run

Business rules run based on two sets of criteria:

- The time that the business rule is configured to run relative to a record being modified or accessed.
- The database operation that the system takes on the record.

The following options are provided to determine the time the business rule should run:

<table>
<thead>
<tr>
<th>Time the business rule should run</th>
<th>Option</th>
<th>When the rule runs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Before</td>
<td>Before</td>
<td>After the user submits the form but before any action is taken on the record in the database.</td>
</tr>
<tr>
<td>After</td>
<td>After</td>
<td>After the user submits the form and after any action is taken on the record in the database.</td>
</tr>
<tr>
<td>Async</td>
<td>Async</td>
<td>When the scheduler runs the scheduled job created from the business rule. The system creates a scheduled job from the business rule after the user submits the form and after any action is taken on the record in the database.</td>
</tr>
</tbody>
</table>

**Note:** Newly created business rules will run during upgrades.

<table>
<thead>
<tr>
<th>Database operation that the system takes on the record</th>
<th>Option</th>
<th>When the rule runs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Insert</td>
<td>Insert</td>
<td>When the user creates a new record and the system inserts it into the database.</td>
</tr>
</tbody>
</table>

**Note:** Asynchronous business rules do not have access to the previous version of a record. Therefore, the changes(), changesTo(), and changesFrom() GlideElement methods do not work with async rule script. However, the condition builder and condition field (advanced view) both support the changes(), changesTo(), and changesFrom() methods.
### Database operation that the system takes on the record (continued)

<table>
<thead>
<tr>
<th>Option</th>
<th>When the rule runs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update</td>
<td>When the user modifies an existing record.</td>
</tr>
<tr>
<td>Query</td>
<td>Before a query for a record or list of records is sent to the database. Typically you should use query for before business rules.</td>
</tr>
<tr>
<td>Delete</td>
<td>When the user deletes a record.</td>
</tr>
</tbody>
</table>

This image shows when different types of business rules run:

#### Business rule processing flow

- **User or system query**
- **Query rules**
- **Display Rules**
- **Before Rules**
- **After Rules**
- **Database query**
- **Database update**

#### Note:
Business rules apply consistently to records regardless of whether they are accessed through forms, lists, or web services. This is one major difference between business rules and client scripts, which apply only when the form is edited.

#### Business rule actions
Business rules can perform a variety of actions. Common types of actions are:

- Changing field values on a form that the user is updating. Field values can be set to specific values available for that field, values copied from other fields, and relative values determined by the user’s role.
- Displaying information messages to the user.
• Changing values of child tasks based on changes to parent tasks.
• Preventing users from accessing or modifying certain fields on a form.
• Aborting the current database transaction. For example, if certain conditions are met, prevent the user from saving the record in the database.

Administrators can set field values, create information messages, and abort transactions without writing a script.

**Prevent recursive business rules**

Avoid using `current.update()` in a business rule script. The `update()` method triggers business rules to run on the same table for insert and update operations, leading to a business rule calling itself over and over. Changes made in before business rules are automatically saved when all before business rules are complete, and after business rules are best used for updating related, not current, objects. When a recursive business rule is detected, the system stops it and logs the error in the system log. However, `current.update()` causes system performance issues and is never necessary.

You can prevent recursive business rules by using the `setWorkflow()` method with the false parameter. The combination of the `update()` and `setWorkflow()` methods is only recommended in special circumstances where the normal before and after guidelines mentioned above do not meet your requirements.

**Related information**

Precedence between data lookup, assignment, and business rules

Business rules in scoped applications

Every business rule is assigned to either a private application scope or to the global scope.

The types of business rules you can create and how you can access those rules varies depending on the scope of the business rule and the scope of the table it runs on.

**Note:** The term *global* can refer to two different aspects of a business rule: the table it runs on and the scope it runs in. Business rules can either run on specific tables or be global. In addition, they can be in the global scope or in a private application scope.
Business rules on specific tables

Most business rules run on a specific table, which is defined in the Table field. You can create business rules on tables in the same scope and on tables that allow configuration records from another application scope. For tables that are in a different scope than the business rule record, the types of rules are limited.

- You can create a rule where When is async with any of the following options:
  - Insert, Update, and Delete database operations. You cannot select Query.
  - Set field values actions and scripts (the Script field).
- You can create a rule where When is before with any of the following options:
  - Insert, Update, and Delete database operations. You cannot select Query.
  - Set field values actions only. You cannot write scripts and you cannot abort the database transaction.
- You cannot create any other types of business rules on tables in a different scope.

Business rules on specific tables cannot be accessed by other business rules or scripts.

Global business rules

⚠️ Warning: Consider using script includes instead of global business rules. Script includes load only on request while global business rules load on every page in the system.

Global business rules are business rules where the Table field is set to Global. Global business rules may be accessible on multiple tables and from other scripts, depending on their scope protection. For a global business rule, define the scope protection by setting the Accessible from field:

- This application scope only: prevents applications in a different scope than the business rule from calling this business rule.
- All application scopes: allows any application to call this business rule.

⚠️ Note: Global business rules do not support domain separation.

Scripts in scoped business rules

When you write a script in a business rule, you can access:
• Any script includes and global business rules in the same scope as the business rule.
• Script includes and global business rules that allow applications in a different scope to call them. To call functions from another scope, you must specify the scope of the function.
• For business rules in a unique scope, you can access the scoped system APIs only.

Create a business rule
You can create any type of business rule to run when a record is displayed, inserted, updated, or deleted, or when a table is queried.

Procedure
1. Navigate to System Definition > Business Rules.
2. Click New.
3. Fill in the fields, as appropriate.

⚠️ Note: You might need to configure the form to see all fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a name for the business rule.</td>
</tr>
<tr>
<td>Table</td>
<td>Select the table that the business rule runs on.</td>
</tr>
<tr>
<td></td>
<td>⚠️ Note: The list shows only tables and database views that meet the scope protections for business rules. Business rules defined for a database view can run only on Query. A business rule for a database view cannot run on insert, update, or delete.</td>
</tr>
<tr>
<td>Application</td>
<td>Application that contains this business rule.</td>
</tr>
<tr>
<td>Accessible from</td>
<td>Scope protection for a global business rule.</td>
</tr>
<tr>
<td></td>
<td>⚠️ Note: This field is visible only when the Table field is set to Global. It does not apply to rules that run on specific tables.</td>
</tr>
<tr>
<td>Active</td>
<td>Select this check box to enable the business rule.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Advanced</td>
<td>Select this check box to see the advanced version of the form.</td>
</tr>
<tr>
<td>When to run</td>
<td></td>
</tr>
<tr>
<td>When</td>
<td>[Advanced] Select when this business rule should execute: display, before, async, or after the database operation is complete.</td>
</tr>
<tr>
<td></td>
<td>Note: Consider setting the Priority for async business rules as the system uses this value when creating the associated scheduled job.</td>
</tr>
<tr>
<td></td>
<td>Note: Newly created async business rules run automatically on upgrade.</td>
</tr>
<tr>
<td>Order</td>
<td>[Advanced] Enter a number indicating the sequence in which this business rule should run. If there are multiple rules on a particular activity, the rules run in the order specified here, from lowest to highest.</td>
</tr>
<tr>
<td>Insert</td>
<td>Select this check box to execute the business rule when a record is inserted into the database.</td>
</tr>
<tr>
<td>Update</td>
<td>Select this check box to execute the business rule when a record is update.</td>
</tr>
<tr>
<td>Delete</td>
<td>[Advanced] Select this check box to execute the business rule when a record is deleted from the database.</td>
</tr>
<tr>
<td>Query</td>
<td>[Advanced] Select this check box to execute the business rule when a table is queried.</td>
</tr>
<tr>
<td>Filter Conditions</td>
<td>Use the condition builder to determine when the business rule should run based on the field values in the selected Table. You can also use the Condition field to build a condition with a script.</td>
</tr>
<tr>
<td></td>
<td>Note: Filters based on string compares are case-sensitive.</td>
</tr>
<tr>
<td>Role Conditions</td>
<td>Select the roles that users who are modifying records in the table must have for this business rule to run.</td>
</tr>
<tr>
<td>Actions</td>
<td></td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Set field values   | Set values for fields in the selected Table using the choice lists:  
• The field  
• The assignment operator:  
  ◦ *To*: An exact value  
  ◦ *Same as*: The value of another field  
  ◦ *To (dynamic)*: A value relative to the user configuring the business rule or a user with a specific role  
• The value |
| Add message        | Select this check box and enter a message that appears when this business rule is run                                                        |
| Abort action       | Select this check box to abort the current database transaction. For example, on a before insert business rule, if the conditions are met, do not insert the record into the database.  
If you select this option, you cannot perform additional actions on the record, such as setting field values and running scripts. You can still display a message to users by selecting the Add message check box and composing the message. |
| Advanced           |                                                                                                                                            |
| Condition          | Create a JavaScript conditional statement to specify when the business rule should run. By adding the condition statement to this field, you tell the system to evaluate the condition separately and run the business rule only if the condition is true.  
If you decide to include the condition statement in the Script field or if you use the condition builder, leave this field blank. To have the instance reevaluate the condition statement a second time before running an async business rule, add the system property `glide.businessrule.async_condition_check` and set the value to true. |
| Script             | [Advanced] Create a script that runs when the defined condition is true. The system automatically populates this field with a function name that matches the *When* value.  
• onAfter  
• onAsync  
• onBefore  
• onDisplay |
Field | Description
---|---
| | **Note:** The function name must match the **When** value. For more information and examples, see Scripting in Business Rules.

4. Click **Submit**.

**Global variables in business rules**

Predefined global variables are available for use in business rules.

Use the following predefined global variables to reference the system in a business rule script.

<table>
<thead>
<tr>
<th>Global variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>current</strong></td>
<td>The current state of the record being referenced. Check for null before using this variable.</td>
</tr>
<tr>
<td><strong>previous</strong></td>
<td>The state of the referenced record prior to any updates made during the execution context, where the execution context begins with the first update or delete operation and ends after the script and any referenced business rules are executed. If multiple updates are made to the record within one execution context, previous will continue to hold the state of the record before the first update or delete operation. Available on update and delete operations only. Not available on asynch operations. Check for null before using this variable.</td>
</tr>
<tr>
<td><strong>g_scratchpad</strong></td>
<td>The scratchpad object is available on display rules, and is used to pass information to the client to be accessed from client scripts.</td>
</tr>
<tr>
<td><strong>gs</strong></td>
<td>References to GlideSystem functions.</td>
</tr>
</tbody>
</table>

The variables **current**, **previous**, and **g_scratchpad** are global across all business rules that run for a transaction.
Prevent null pointer exceptions
In some cases, there may not be a current or previous state for the record when a business rule runs, which means that the variables will be null. To check for null before using a variable, add the following code to your business rule:

```java
if (current == null) // to prevent null pointer exceptions.
    return;
```

Define variables
User-defined variables are globally scoped by default. If a new variable is declared in an order 100 business rule, the business rule that runs next at order 200 also has access to the variable. This may introduce unexpected behavior.

To prevent such unexpected behavior, always wrap your code in a function. This protects your variables from conflicting with system variables or global variables in other business rules that are not wrapped in a function. Additionally, variables such as current must be available when a function is invoked in order to be used.

The following script is vulnerable to conflicts with other code. If the variable gr is used in other rules, the value of the variable may unexpectedly change.

```java
var now_GR = new GlideRecord('incident');
gr.query();
while(gr.next()) {
    //do something
}
```

When this script is wrapped in a function, the variable is available only within the function and does not conflict with other functions using a variable named gr.

```javascript
myFunction();

function myFunction() {
    var now_GR = new GlideRecord('incident');
gr.query();
while(gr.next()) {
    //do something
}
}
```
Use business rules and client scripts to control field values

Implement both business rules and client scripts for a field to enable users to set record values properly using both forms and lists, and to see immediate changes to the values in forms as edits are made.

The problem with using only a client script or a business rule to control updates to a field is that fields can be changed on either a form or a list. Client scripts and UI policies run on forms only (client-side) and do not apply to list editing. Allowing list editing with client scripts running on fields in a form can result in incorrect data being saved to the record. For systems in which client scripts or UI policies apply to forms, either disable list editing or create appropriate business rules or access control to control the setting of values in the list editor. A side effect of this is that security measures implemented in client scripts are easy to circumvent. The user only needs to edit the field in a list.

Business rules on a form are not dynamic, the user must update the record for the change to be seen. This makes using client scripts the preferred method for controlling field values on forms.

When using both a business rule and client script to control field values, the update behavior is the same across the system. This means that updated values are not different depending on whether a list of form is used to make the change. This means that the same functionality must be implemented twice, once in a client script and once in a business rule or access control.

Example: Use a business rule to create email addresses during user record import

An organization has a client script that sets the email address for a user to first.last@company.com. The administrator likes this because he can see the email address immediately when he enters the user's information. The administrator then performs a bulk import of users from a spreadsheet containing the users' first and last names. His expectation is that each user's email address will be set automatically, as they are when he edits the form. Since the client script runs only on the form (the interface to the record), it has no effect on data imported into the record from outside that interface, and no email addresses are created. To solve this problem, the administrator implements a business rule that runs when the import occurs and creates the email addresses.

Example: Prevent list edit for a field that is not editable in the form

An organization wants to hide the Priority field on an incident form if the assignment group is Development. They create a UI policy on the incident form to do this, but their users can still see and edit the Priority field using the list editor. To rectify this, apply an access control to prevent read access to the Priority field when the assignment group is Development.
Using NULL as a field value

The string NULL has a particular role in scripts and is a reserved word. The reserved word is NULL in all capital letters. A field with the value Null or null, for example, is acceptable. Only use NULL to clear out a particular field.

Any NULL field values obtained from an import set data source are inserted into the staging table as empty field values. You should not use the term NULL as a field value in import set transform maps or anywhere in the First name or Last name fields. Also, do not use NULL in reference fields as the system interprets the value as a string containing the word NULL, not as a reserved word.

Display business-rules

Display rules are processed when a user requests a record form.

The data is read from the database, display rules are executed, and the form is presented to the user. The current object is available and represents the record retrieved from the database. Any field changes are temporary since they are not yet submitted to the database. To the client, the form values appear to be the values from the database; there is no indication that the values were modified from a display rule. This is a similar concept to calculated fields.

The primary objective of display rules is to use a shared scratchpad object, g_scratchpad, which is also sent to the client as part of the form. This can be useful when you need to build client scripts that require server data that is not typically part of the record being displayed. In most cases, this would require a client script making a call back to the server. If the data can be determined prior to the form being displayed, it is more efficient to provide the data to the client on the initial load. The form scratchpad object is an empty object by default, and used only to store name:value pairs of data.

To populate the form scratchpad with data from a display rule:

```javascript
// From display business rule
g_scratchpad.someName = "someValue";
g_scratchpad.anotherName = "anotherValue";

// If you want the client to have access to record fields not being displayed on the form
g_scratchpad.created_by = current.sys_created_by;

// These are simple examples, in most cases you'll probably perform some other
// queries to test or get data
```

To access the form scratchpad data from a client script:
Task Active State Management business rule

This business rule determines whether the active field value needs to change based on changes to the State field.

The Task Active State Management business rule is executed when the State is changed for a task record. Its execution order is 50, and it runs before most other task business rules.

If the current task table has the close_states attribute defined on its table, or if it is inherited from a higher-level table, then the rule determines whether the active field needs to change. This is done by comparing the previous and current state values.

- If the state changes from an active state to an inactive state, the Active field is set to false.
- If the state changes from an inactive state to an active state, the Active field is set to true, effectively re-activating or re-opening the task.

It is recommended that you leverage the (current.active.changesTo([true/false])) action in your business rule, as opposed to creating rules on each task table that mark tasks as inactive or active.

Example business rule scripts

Find an example business rule script that helps you with a requirement of your organization.

Compare date fields in a business rule

It is possible to compare two date fields or two date and time fields in a business rule, and abort a record insert or update if they are not correct.

For example, you may want a start date to be before an end date. The following is an example script:

```javascript
if (!current.u_date1.nil() && !current.u_date2.nil()) {
    var start = current.u_date1.getGlideObject().getNumericValue();
    var end = current.u_date2.getGlideObject().getNumericValue();
    if (start > end) {
        gs.addInfoMessage('start must be before end');
        current.u_date1.setError('start must be before end');
    }
}
```
This example has been tested in global scripts, and may need changes to work in scoped scripts. In addition to possibly needing API changes, security is more strict in scoped scripts.

As a good practice, make the business rule a before rule for insert and update actions. In the example script:

• `u_date1` and `u_date2` are the names of the two date fields. Replace these names with your own field names.

• The first line checks that both fields actually have a value.

• The next two lines create variables that have the dates' numerical values.

• The next two lines create different alert messages for the end user: one at the top of the form and one by the `u_date1` field in the form.

• The last line aborts the insert or update if the date fields are not correct.

Here is a more complex example of the above comparison. If you have more than one pair of start and end dates, you can use arrays as shown. Additionally, this script requires the input dates to be within a certain range, in this case, no fewer than 30 days in the past and no more than 365 days in the future.

```javascript
// Enter all start and end date fields you wish to check, as well as the previous values // Make sure that you keep the placement in the sequence the same for all pairs
var startDate = new Array(current.start_date, current.work_start);
var prevStartDate = new Array(previous.start_date, previous.work_start);
var endDate = new Array(current.end_date, current.work_end);
var prevEndDate = new Array(previous.end_date, previous.work_end);

// The text string below is added to the front of 'start must be before end'
var userAlert = new Array('Planned', 'Work');

// Set the number of Previous Days you want to check
var pd = 30;
// Set the number of Future Days you want to check
var fd = 365;

// You shouldn't have to modify anything below this line

var nowdt = new GlideDateTime();
nowdt.setDisplayValue(gs.nowDateTime());
var nowMs = nowdt.getNumericValue();
var pdMs = nowMs;
```
// Subtract the product of previous days to get value in milliseconds
pdms -= pd * 24 * 60 * 60 * 1000;
var fdms = nowMs;

// Add the product of future days to get value in milliseconds
fdms += fd * 24 * 60 * 60 * 1000;
var badDate = false;

// Iterate through all start and end date / time fields
for (x = 0; x < startDate.length; x++) {
    if (((startDate[x].nil()) && (endDate[x].nil()))) {
        var start = startDate[x].getGlideObject().getNumericValue();
        var end = endDate[x].getGlideObject().getNumericValue();
        if (start > end) {
            gs.addInfoMessage(userAlert[x] + ' start must be before end');
            startDate[x].setError(userAlert[x] + ' start must be before end');
            badDate = true;
        } else if (prevStartDate[x] !== startDate[x]) {
            if (start < pdms) {
                gs.addInfoMessage(userAlert[x] + ' start must be fewer than ' + pd + ' days ago');
                startDate[x].setError(userAlert[x] + ' start must be fewer than ' + pd + ' days ago');
                badDate = true;
            }
            else if (prevEndDate[x] !== endDate[x]) {
                if (end > fdms) {
                    gs.addInfoMessage(userAlert[x] + ' end must be fewer than ' + fd + ' days ahead');
                    endDate[x].setError(userAlert[x] + ' end must be fewer than ' + fd + ' days ahead');
                    badDate = true;
                }
            }
        }
    }
}
if (badDate == true) {
    current.setAbortAction(true);
}

Parse XML payloads

Fields in XML format can be parsed with the system's `getXMLText` function.

Fields that get inserted into the database in XML format, such as the payload of an `ecc_event` row, can be parsed with the system’s `getXMLText` function. The `getXMLText` function takes a string and an XPATH expression. For example:

```javascript
var name = gs.getXMLText("<name>joe</name>", "//name");
```

returns the string 'joe'.
Assuming that the field "payload" contains XML, the function call might look like:

```javascript
var name = gs.getXMLText(current.payload, "//name");
```

For information on XPATH, visit w3schools.

**Abort a database action in a before business-rule**

In a before business rule script, you can cancel or abort the current database action using the `setAbortAction()` method.

For example, if the before business rule is executed during an insert action, and you have a condition in the script that calls `current.setAbortAction(true)`, the new record stored in current is not created in the database. The business rule continues to run after calling `setAbortAction()` and all subsequent business rules will execute normally. Calling this method only prevents the database action from occurring.

You can use the `isActionAborted()` method to determine if the current database action (insert, update, delete) is going to be aborted. `isActionAborted()` is initialized for new threads and the `next()` method explicitly sets its value to false.

> Note: `setAbortAction()` can only be executed from the same scope as the record whose action is being aborted. `current.setAbortAction` is not honored if executed in a business rule that is defined in a different scope.

**Determine the operation that triggered the business rule**

You can write a script for a business rule that is triggered on more than one database action.

If you want the business rule script to dynamically branch depending on the action that triggered the event, you can use the `operation()` function. For example:

```javascript
if(current.operation() == "update") {
    current.updates ++;
} else if(current.operation() == "insert") {
    current.updates = 0;
}
```

**Use an OR condition in a business rule**

An **OR** condition can be added to any query part within a business rule.

An **OR** condition can be added to any query part within a business rule with the `addOrCondition()` method. The example below shows a query for finding all the incidents that have either a 1 or a 2 priority. The first `addQuery()` condition is defined as a variable and is used in the **OR** condition.
var inc = new GlideRecord('incident');
var qc = inc.addQuery('priority','1');
qc.addOrCondition('priority','2');
inc.query();
while(inc.next()) {
    // processing for the incident goes here
}

The following script is a more complex example, using two query condition variables doing the equivalent of (priority = 1 OR priority = 2) AND (impact = 2 OR impact = 3). The results of the OR condition are run with two variables, qc1 and qc2. This allows you to manipulate the query condition object later in the script, such as inside an IF condition or WHILE loop.

var inc = new GlideRecord('incident');
var qc1 = inc.addQuery('priority','1');
qc1.addOrCondition('priority','2');
var qc2 = inc.addQuery('impact','2');
qc2.addOrCondition('impact','3');
inc.query();
while(inc.next()) {
    // processing for the incident goes here
}

Reference a Glide list from a business rule

A field defined as a glide list is an array of values stored in a single field.

Here are some examples of how to process a glide_list field when writing business rules. Generally a glide_list field contains a list of reference values to other tables.

Examples

For example, the Watch list field within tasks is a glide_list containing references to user records.

The code below shows how to reference the field.

```javascript
// list will contain a series of reference (sys_id) values separated by a comma
// array will be a javascript array of reference values
var list = current.watch_list.toString();
var array = list.split(",");
for (var i=0; i < array.length; i++) {
    gs.print("Reference value is: " + array[i]);
}
```
You can also get the display values associated with the reference values by using the `getDisplayValue()` method as shown below.

```javascript
// list will contain a series of display values separated by a comma
// array will be a javascript array of display values
var list = current.watch_list.getDisplayValue();
var array = list.split(",");
for (var i=0; i < array.length; i++) {
    gs.print("Display value is: " + array[i]);
}
```

Output:

- Display value is: Abel Tuter
- Display value is: Ashley Leonesio
- Display value is: Charles Beckley
- Display value is: Cherie Fuhri

**Use `indexOf("searchString")` to find a string in a Glide list**

Use `indexOf("searchString")` to return the location of the string passed into the method if the glide list field, such as a Watch list, has at least one value in it.

If the field is empty, it returns `undefined`. To avoid returning an undefined value, do any of the following:

- Force the field to a string, such as:
  ```javascript
  watch_list.toString().indexOf("searchString")
  ```
- Check for an empty Glide list field with a condition before using `indexOf()`, such as: `if (watch_list.nil() || watch_list.indexOf("searchString") == -1)`

**Lock user accounts**

You can lock user accounts if the user is not active.

The following business rule script locks user accounts if the user is not active in the LDAP directory or the user does not have self-service, itil, or admin access to the instance.
/ Lock accounts if bcNetIDStatus != active in LDAP and user does not have self-service, itil or admin role
var rls = current.accumulated_roles.toString();
if(current.u_bcnetidstatus == 'active' && (rls.indexOf(',itil,') > 0 ||
    rls.indexOf(',admin,') > 0 ||
    rls.indexOf(',ess,') > 0 )) {
    current.locked_out = false; }
else {
    current.locked_out = true; }

var now_GR = new GlideRecord("sys_user");
gr.query();
while(gr.next()) {
    gr.update();
    gs.print("updating " + gr.getDisplayValue());
}

Default before-query business rule
You can use a query business rule that executes before a database query is made.
Use this query business rule to prevent users from accessing certain records. Consider the following example from a default business rule that limits access to incident records.
• Name: incident query
• Table: Incident
• When: before, query
• Script:

if(!gs.hasRole("itil") && gs.isInteractive()) {
    var u = gs.getUserId();
    var qc =
current.addQuery("caller_id",u).addOrCondition("opened_by",u).addOrCondition("watch_list", "CONTAINS",u);
    gs.print("query restricted to user: " + u); }

This example prevents users from accessing incident records unless they have the itil role, or are listed in the Caller or Opened by field. So, for example, when self-service users open a list of incidents, they can only see the incidents they submitted.
Note: You can also use access controls to restrict the records that users can see.

Script includes

Script includes are used to store JavaScript that runs on the server.

Create script includes to store JavaScript functions and classes for use by server scripts. Each script include defines either an object class or a function.

Consider using script includes instead of global business rules because script includes are only loaded on request.

Script include form

Script includes have a name, description and script. They also specify whether they are active or not, and whether they can be called from a client script.

Procedure

To access script includes, navigate to System Definitions > Script Includes.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the script include. If you are defining a class, this must match the name of the class, prototype, and type. If you are using a classless (on-demand) script include, the name must match the function name.</td>
</tr>
<tr>
<td>Client callable</td>
<td>Makes the script include available to client scripts, list/report filters, reference qualifiers, or if specified as part of the URL.</td>
</tr>
<tr>
<td>Application</td>
<td>The application where this script include resides.</td>
</tr>
<tr>
<td>Accessible from</td>
<td>Sets which applications can access this script include:</td>
</tr>
<tr>
<td></td>
<td><strong>All application scopes</strong>&lt;br&gt;Can be accessed from any application scope.</td>
</tr>
<tr>
<td></td>
<td><strong>This application scope only</strong>&lt;br&gt;Can be accessed only from the current application scope.</td>
</tr>
<tr>
<td>Active</td>
<td>Enables the script include when selected. Uncheck the active field to disable the script include.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Description</td>
<td>Provides descriptive content regarding the script include.</td>
</tr>
<tr>
<td>Script</td>
<td>Defines the server side script to run when called from other scripts. The script must define a single JavaScript class or a global function. The class or function name must match the Name field.</td>
</tr>
<tr>
<td>Package</td>
<td>The package that contains this script include.</td>
</tr>
<tr>
<td>Created by</td>
<td>The user who created this script include.</td>
</tr>
<tr>
<td>Updated by</td>
<td>The user who most recently updated this script include.</td>
</tr>
<tr>
<td>Protection policy</td>
<td>Sets the level of protection for the script include:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong></td>
</tr>
<tr>
<td></td>
<td>Allows anyone to read and edit this downloaded or installed script include.</td>
</tr>
<tr>
<td></td>
<td><strong>Read-only</strong></td>
</tr>
<tr>
<td></td>
<td>Allows anyone to read values from this downloaded or installed script include. No one can change script values on the instance on which they download or install the script include.</td>
</tr>
<tr>
<td></td>
<td><strong>Protected</strong></td>
</tr>
<tr>
<td></td>
<td>Provides intellectual property protection for application developers. Customers who download the script include cannot see the contents of the script field. The script is encrypted in memory to prevent unauthorized users from seeing it in plain text.</td>
</tr>
</tbody>
</table>

**Related lists on the form view:**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Versions</td>
<td>Shows all versions of the script include. Use this list to compare versions or to revert to a previous version. See Versions.</td>
</tr>
</tbody>
</table>

**Use script includes**

Script includes are found under System Definition or System UI. You can call existing script includes from a script.

To create an entirely new script include, you can follow the format of any of the existing script includes. In the example, the name of your Script Include is 'NewInclude' and there is a single function called 'myFunction.' It is important that the name of the script include match the name of the class, prototype,
and type. When you create a new script include and give it a name, the system provides you a code snippet with the class and prototype set up properly.

```javascript
var NewInclude = Class.create();

NewInclude.prototype = {
  initialize: function() {},

  myFunction: function() { // Put function code here,
  type: 'NewInclude';

You could then use the 'myFunction' line like this:

```javascript
var foo = new NewInclude();
foo.myFunction();
```

**Note:** Try not to modify a ServiceNow supplied script include. If you want a script include that does something similar to an existing one, copy it and make changes to the copy or consider extending the object. This is a common practice when using GlideAjax.

### Privacy settings

The privacy setting for a client-callable script-include can be public or private. Most client-callable script-includes are marked private by default.

The private privacy-setting means that guests who access public pages cannot access the client-callable script-include. A private script cannot be executed by a non-logged-in user.

A public privacy-setting means that the client script can be executed by non-logged-in users that create an appropriate HTTP request. This can create a security problem if the client script provides confidential information.

The following script includes remain public by default because public pages need to access them:

- GlideSystemAjax
- SysMessageAjax
- KnowledgeMessagingAjax
- KnowledgeAjax
- PasswordResetAjax
Change privacy on all client-callable script includes
Change the privacy setting on all client-callable script includes.

To provide further control over all client-callable script includes, administrators can add the `glide.script.ccsi.ispublic` property. This property changes the visibility of client-callable script includes by making them all public or private. Configure the property as follows:

<table>
<thead>
<tr>
<th>Title</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>glide.script.ccsi.ispublic</td>
</tr>
<tr>
<td>Type</td>
<td>true</td>
</tr>
<tr>
<td>Value</td>
<td>false</td>
</tr>
</tbody>
</table>

**Note:** To learn more about this property, see [Privacy on client-callable script includes](#) in Instance Security Hardening Settings.

Change privacy on a single client callable script include
Change the privacy setting for a single client-callable script include by adding the `isPublic()` function.

The `isPublic()` setting takes precedence over the `glide.script.ccsi.ispublic` property. For example, if the property is set to `false`, making all client-callable script-includes private, and a script sets `isPublic()` to `true`, the script is public.

To change the privacy for a single client-callable script include, add the following method to the script include:

```javascript
isPublic:function(){return[true/false];},
```

Make the NewInclude client script private.

```javascript
var NewInclude =Class.create();
NewInclude.prototype={
    initialize:function(){},
    myFunction:function()//Put function code here),
    isPublic:function(){return false;},
    type:'NewInclude'};
```
Using discovery script includes

Discovery script includes define JavaScript classes that you can use to accomplish Discovery tasks.

Using GlideRecordUtil to Work with GlideRecords

GlideRecordUtil is a utility class that provides methods that are useful for working with GlideRecords during Discovery.

Getting a GlideRecord Instance

To get a GlideRecord instance for a given configuration item, and of the correct class and table, use the `getCIGR(sys_id)` method. For example, the following code gets the GlideRecord of a CI with the sys_id of 2dfd7c8437201000deeabfc8bcbe5d56:

```javascript
var now_GR = new GlideRecordUtil().getCIGR("2dfd7c8437201000deeabfc8bcbe5d56");
```

To retrieve any hierarchical table without knowing its class type, use the `getGR(base_table, sys_id)` method. For instance, if you need to get a GlideRecord for a computer class CI, you may not know if it is a computer class or more specifically a Windows server class or Linux server class. Using this method guarantees that you have a GlideRecord with the correct class. This is important because different classes have different attributes—in this case, a Windows server has attributes different from those of a Linux server. You must get a GlideRecord in the correct class or attributes may be missing. The following is a typical example of how to do this:

```javascript
var now_GR = new GlideRecordUtil().getGR("cmdb_ci_computer", "2dfd7c8437201000deeabfc8bcbe5d56");
```

Getting All the Fields In a GlideRecord

The `getFields(now_GR)` method returns a JavaScript object, such as a hash map, of all the fields or attributes that exist in a given GlideRecord.

```javascript
var now_GR = new GlideRecordUtil().getGR("cmdb_ci_computer", "2dfd7c8437201000deeabfc8bcbe5d56");
var fields = new GlideRecordUtil().getFields(now_GR);
gs.log(fields.join(" ")); // List all the fields that are in a computer CI
```

Populating GlideRecord Object Fields

The `populateFromGR(hashmap, gr, ignore)` method allows you to take a GlideRecord object and populate its fields and values into a JavaScript object. The third argument (`ignore`) is an optional JavaScript object that allows you to exclude certain fields. For example, you may not care about `sys_created_by` or `sys_updated_by` fields in a GlideRecord.
The `mergeToGR(hashmap, gr, ignore)` method allows you to populate a GlideRecord with a field/value-paired object. The ignore argument stops specified fields from being updated. The following code example updates a computer record's `name` and `os` fields, but does not update the `sys_created_by` field:

```javascript
var now_GR = new GlideRecordUtil().getGR("cmdb_ci_computer", "2dfd7c843721000deeabfcbcbce5d56");
var obj = {"name": "xyz", "os": "windows 2000", "sys_created_by": "aleck.lin"};
var ignore = {"sys_created_by": true};
new GlideRecordUtil().mergeToGR(obj, gr, ignore);
gr.update();
```

**Getting Table Hierarchies**

The `getTables(table)` method returns a list of table hierarchies, as shown in the following example:

```javascript
var tables = new GlideRecordUtil().getTables("cmdb_ci_linux_server");
gs.log(tables.join(','));
// The result would be "cmdb_ci, cmdb_ci_computer, cmdb_ci_server, cmdb_ci_linux_server".
```

**Using DiscoveryException and AutomationException**

When writing Discovery sensors and sensor-related scripts, you may want to use DiscoveryException or AutomationException to indicate that an exception has come from Discovery.

The `DiscoveryException` script include extends `AutomationException`, which extends the `GenericException` class. The following example uses `DiscoveryException` to throw an exception:

```javascript
function foo() {
    if(//condition matches) throw new DiscoveryException("The message", "The cause");
}
```

The first argument takes the message of the exception and the second argument (optional) takes the cause of the exception. You may also want to catch the exception and log it as shown in the example below:

```javascript
try {
    foo();
}
```
The above example also applies for `AutomationException`. `DiscoveryException` is typically used to provide exception processing specifically for Discovery, while `AutomationException` is used for exception processing that applies to both Orchestration and Discovery.

**UI pages**

UI pages can be used to create and display forms, dialogs, lists and other UI components.

Use UI pages as widgets on dashboards. To find the UI pages, navigate to **System UI > UI Pages**.

This functionality requires a knowledge of HTML or Jelly. You can also create simple AngularJS applications using UI pages. To learn more, see the Building Apps with AngularJS developer training.
The UI page form provides the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name used to invoke the page via a URL (must not contain spaces).</td>
</tr>
<tr>
<td>HTML</td>
<td>Main component of the page, and it defines what will be rendered when the page is shown. It can contain either static XHTML or dynamically generated content defined as Jelly, and it can call script includes and UI Macros.</td>
</tr>
</tbody>
</table>
| Client Script  | Client-side JavaScript that runs in the browser (e.g., functions called by buttons, etc.). It is intended to handle any client-side processing needed, for example setting focus to a field, or other interactive DHTML features after a page is loaded. Ultimately, a UI page's Client Scripts are deployed to the browser within a `<script/>` tag,
UI page (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field</td>
<td>so it could be defined within the page's HTML field to achieve the same effect. Using the Client Script field instead to define these scripts makes things much more tidy and readable though, and it keeps the Jelly and HTML from becoming unmanageable.</td>
</tr>
<tr>
<td>Processing Script</td>
<td>Script that runs on the server when the page is submitted. This is useful if your page has a form (defined with the <code>&lt;g:ui_form/&gt;</code> or <code>&lt;g:form/&gt;</code> tags).</td>
</tr>
<tr>
<td>obsolete-custom-processors</td>
<td>Note: This feature is deprecated. While legacy, custom processors will continue to be supported, creating new custom processors has been deprecated. Instead, please use the Scripted REST APIs. The following information is left in the documentation for existing processors only.</td>
</tr>
</tbody>
</table>

Related lists on the form view:

<table>
<thead>
<tr>
<th>Field</th>
<th>Input Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Versions</td>
<td>Shows all versions of the UI page. Use this list to compare versions or to revert to a previous version.</td>
</tr>
</tbody>
</table>

A UI page can be secured by creating an ACL with the following parameters:

- **Type**: ui_page
- **Operation**: read
- **Name**: name of the UI page to be protected

For details on creating an ACL rule, see Create an ACL rule.

**UI page access**

Each UI page has a URL computed from the application scope, page name, and the .do file extension.

For example, to display the page called glidewindow_example on the demo system, you would navigate to https://<instance name>.service-now.com/glidewindow_example.do. If the page was part of a custom application called example_app, you would instead navigate to https://<instance name>.service-now.com/x_example_app_glidewindow_example.do.

You can also add additional parameters to a URL that can be accessed within a page's HTML section as jelly variables. That is, appending arguments to the URL as follows: /my_test_page.do?sysparm_verbose=true creates jelly variables called *verbose* that can be accessed as follows:
A common practical example of this might be retrieving a database record for display. To build a list of a user's roles, pass in a parameter with the user's sys_id. 

Invoke the following UI page to display a list of roles for that user with Jelly code:

```
role_select.do?sysparm_user=5137153cc611227c000bbd1bd8cd2007
```

```
<j:set var = "jvar_user_id" value = "${sysparm_user}" />

<g:evaluate> var userRoles = new GlideRecord('sys_user_has_role');
    userRoles.addQuery('user','${jvar_user_id}');
    userRoles.query();
</g:evaluate>

<select id='select_role'>
    <j:while test = "${userRoles.next()}">
        <option value = "${userRoles.sys_id}" > ${userRoles.role.name} </option>
    </j:while>
</select>
```

An exception to be careful of, though, is the reserved variable name sys_id. This variable always contains the ID of the UI page itself, regardless of what is specified in the URL. A common substitute variable name is sysparm_id.

Do not use URL parameters to load client scripts in UI pages. The system no longer evaluates scripts that are passed by URL parameter. If your implementation depends on this behavior, you can add the system property [glide.security.disable_ui_pages_sysparm_client_script] and set it to false to temporarily allow the evaluation of URL parameters passing scripts in UI pages.

**UI page process scripts**

If your UI page contains a form (uses the <g:form> tag), you can submit the form and have the process script run.

The processing script can naturally access fields on the form. For example, if your form contained the application_sys_id field:

```
<g:ui_form><p>Click OK to run the processing script.</p> <g:dialog_buttons_ok_cancel
    ok = "return true"/> <input type = "hidden" name = "application_sys_id" value = "499836460a0a0b1700003e7ad950b5da"/>
</g:ui_form>
```

You could then access it using just application_sys_id:

ℹ️ Note:

- GlideSession replaces Packages.com.glide.sys.GlideSession
var application = new GlideRecord('hr_application');
application.get(application_sys_id);
application.status = "Rejected";
application.update();
var urlOnStack = GlideSession.get().getStack().bottom();
response.sendRedirect(urlOnStack);

If you are using the UI page for a dialog, you can also reference the most recent URL on the stack using the code above and then send the response to that location. This is useful if you want to have the dialog's processing script update something and then redisplay the screen that brought up the dialog.

**UI Macros**

UI macros are discrete scripted components administrators can add to the user interface.

UI macros are typically controls that provide inputs or information not provided by existing field types. By default, the system provides UI macros for a variety of user interface elements such as:

- All formatters
- The Service Catalog cart
- The action icons next to fields
- The action icons on forms and lists
- The widgets of a content management system
- The Orchestration activity designer

Administrators can create their own UI macros to provide custom controls or interfaces. Creating UI macros requires knowledge of *Jelly script*. Review the existing UI macros for examples and suggested approaches. Those who want to build custom interfaces with JavaScript technologies should consider Service Portal as an alternative.

**Calling UI macros**

Administrators can call UI macros from certain record types associated with the user interface.
### Calling UI Macros by record type

<table>
<thead>
<tr>
<th>Record type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dictionary attribute</td>
<td>Display an icon for a reference field:</td>
</tr>
<tr>
<td></td>
<td><code>ref_contributions=ui_macro_name</code></td>
</tr>
<tr>
<td>UI page</td>
<td>Display something on a UI page:</td>
</tr>
<tr>
<td></td>
<td><code>&lt;g:macro_invoke macro=&quot;ui_macro_name&quot; /&gt;</code></td>
</tr>
<tr>
<td>UI macro</td>
<td>Call a UI macro from another UI macro:</td>
</tr>
</tbody>
</table>
|                   | `<?xml version= "1.0" encoding= "utf-8"&nbsp;?><j:jelly trim= "false" xmlns:j="jelly:core" xmlns:g="glide"
xmlns:j2="null" xmlns:g2="null">
  <g:ui_macro_name />
  <g:ui_macro_name_2 />
</j:jelly>` |

### UI macro form

Each UI macro record consists of a name and an XML document written in Jelly code.

### UI macro fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>A unique and descriptive name for this macro.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to render the element as defined. Clear the check box to disable the element without deleting the code. For example, the <code>email_reply</code> macro is inactive by default.</td>
</tr>
<tr>
<td>Description</td>
<td>Describe the purpose of the macro and parameters passed to it.</td>
</tr>
<tr>
<td>XML</td>
<td>Jelly script that defines the macro.</td>
</tr>
</tbody>
</table>

### Processors

Processors provide a customizable URL endpoint that can execute arbitrary server-side JavaScript code and produce output such as TEXT, JSON, or HTML. Creating custom processors is deprecated.
Note: This feature is deprecated. While legacy, custom processors will continue to be supported, creating new custom processors has been deprecated. Instead, please use the Scripted REST APIs. The following information is left in the documentation for existing processors only.

Warning: When creating a processor, ensure that you use parameter names that are specific to your processor. For example, if your processor exports a list of legal records, and a necessary parameter is the recipient's email address, don't use “email” as the parameter name. Create a more processor specific parameter name, such as legal_export_recipient_email. Failure to do so, and using instance parameter names, such as id, table, sys_id, service, catalog_id, or view (and others), can cause unexpected results.

When to create processors

Do not create custom processors. This feature is deprecated. Please use the REST APIs instead of creating custom processors. The remaining information is left for existing processors only.

Processor form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Unique name of the processor.</td>
</tr>
<tr>
<td>Type</td>
<td>Programming language of the processor script. Options include:</td>
</tr>
<tr>
<td></td>
<td>• java: do not select this option</td>
</tr>
<tr>
<td></td>
<td>• script</td>
</tr>
<tr>
<td>Application</td>
<td>Application containing this record.</td>
</tr>
<tr>
<td>Active</td>
<td>Flag to enable or disable the record.</td>
</tr>
<tr>
<td>CSRF protect</td>
<td>Option to protect the processor from running unless the instance uses a CSRF token.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of the processor's function or purpose.</td>
</tr>
<tr>
<td>Parameters</td>
<td>List of available input parameters. Specify parameter values in the URL as &lt;parameter name&gt;=&lt;parameter value&gt;.</td>
</tr>
</tbody>
</table>
### Processor API components

Processors have access to dedicated API classes, objects, and methods.

#### Processor API components

<table>
<thead>
<tr>
<th>Class, object, or method</th>
<th>Description</th>
</tr>
</thead>
<tbody>

Secure and protect a processor

You can protect your processor against unauthorized use by using role restrictions, and protect it by requiring a CSRF token.

About this task

⚠️ Note: This feature is deprecated. While legacy, custom processors will continue to be supported, creating new custom processors has been deprecated. Instead, please use the Scripted REST APIs. The following information is left in the documentation for existing processors only.

You can re-use a table’s user role restrictions to protect it from access by your processor. This protection method assumes the processor will access table data.

Procedure

1. Create or select a user role that has access to the table the processor script calls.

2. Navigate to System Definition > Processors.

3. In Script, add the following code block.
4. Update the code block to use other access restrictions as needed.
   Available access functions include:
   • canCreate()
   • canRead()
   • canWrite()
   • canDelete()

5. Click Update.

Protect a processor with a CSRF token
You can protect a processor by requiring a CSRF token.

About this task
Script type processors can require a CSRF token check before the processor runs.

Procedure
1. Navigate to System Definition > Processors.
2. Open a processor record.
3. Select the CSRF protect option.
4. Click Update.

Create a simple processor
Create a simple processor to execute a script from a URL query. This feature is deprecated.
About this task

⚠ **Note:** This feature is deprecated. While legacy, custom processors will continue to be supported, creating new custom processors has been deprecated. Instead, please use the Scripted REST APIs. The following information is left in the documentation for existing processors only.

The following steps assume that you have your own demonstration instance.

**Procedure**

1. Navigate to **System Definition > Processors**.
2. Click **New**.
3. Enter the following information.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Hello</td>
</tr>
<tr>
<td>Type</td>
<td>Script</td>
</tr>
<tr>
<td>Path</td>
<td>Hello</td>
</tr>
</tbody>
</table>
| Script | var name= g_request.getParameter("name"); 
g_processor.writeOutput("text/plain","Hello +name"); |

4. Click **Submit**.
5. Enter a URL query to the instance with the following format: https://instance.service-now.com/processor_name.do?parameter=value. For example: https://instancename.service-now.com/Hello.do?name=world.

**Create a multi-table processor**

Create a multi-table processor that reports the number of rows in any table on your instance. This feature is deprecated.

About this task

⚠ **Note:** This feature is deprecated. While legacy, custom processors will continue to be supported, creating new custom processors has been deprecated. Instead, please use the Scripted REST APIs. The following information is left in the documentation for existing processors only.
The multi-table processor protects itself from performance and security violations by confirming that the user is authorized to read the table. It does not report on certain tables that are too large to query safely.

**Procedure**

1. Navigate to *System Definition > Processors.*
   The list of processors appears.

2. Click **New.**

3. Enter the following information.

<table>
<thead>
<tr>
<th>Name</th>
<th>TableSize</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type</td>
<td>Choose Javascript</td>
</tr>
<tr>
<td>Description</td>
<td>Return number of records in a table</td>
</tr>
<tr>
<td>Parameters</td>
<td>SIZE</td>
</tr>
<tr>
<td>Path</td>
<td>&lt;leave empty&gt;</td>
</tr>
</tbody>
</table>

**Script**

```javascript
G_response.setContentType('text/html;charset=UTF-8');
if(g_target === 'sys_email' || g_target === 'sys_log') {
    g_processor.writeOutput(g_target + ' table is too large to quickly count');
} else {
    var count = new GlideAggregate(g_target);
    if( count.canRead() ) {
        count.addAggregate('COUNT');
        count.query();
        var records = 0;
        if (count.next()) {
            records = count.getAggregate('COUNT');
        }
        g_processor.writeOutput('table ' + g_target + ' has ' + records + ' records');
    } else {
        g_processor.writeOutput('You do not have access to table ' + g_target);
    }
}
```

4. Click **Save.**

5. Test the new processor by entering the following URLs:
   https://<instancename>.service-now.com/incident.do?SIZE
https://<instancename>.service-now.com/sys_user.do?SIZE
Your instance reports the number of records in the table. For example, table incident has 82 records.

Create a custom processor
You can create a custom processor to execute a script from a URL query. This feature is deprecated.

About this task

Note: This feature is deprecated. While legacy, custom processors will continue to be supported, creating new custom processors has been deprecated. Instead, please use the Scripted REST APIs. The following information is left in the documentation for existing processors only.

When complete, you will be able to:

• Create a new processor
• Run a script from a URL query

The following example steps assume you have your own demonstration instance.

Procedure
1. Navigate to System Definition > Processors.
2. Click New.
3. For Name, enter Hello.
4. For Type, select script.
5. For Path, enter Hello.
6. For Script, enter the following code.

```javascript
var name = g_request.getParameter("name");
g_processor.writeOutput("text/plain", "Hello " + name);
```
7. Click Submit.
8. Logout of the instance and open a new browser window.
9. Enter a URL query to the instance with the following format: https://instance.service-now.com/processor_name.do?parameter=value. For example: https://<instance name>.service-now.com/Hello.do?name=world.
10. When prompted, enter credentials for valid user.
**Scripts - Background module**

Administrators can use the Scripts - Background module to run arbitrary JavaScript code from the server.

The Scripts - Background module consists of the following components.

- A text field to enter JavaScript
- A selector to specify the application scope
- A **Run script** button
- A list of available scripts
- A **Record for rollback?** check box. Selected by default, this creates a rollback context for the script execution. After the script is run, click the **Script execution and recovery available here** link to go to the **Script Execution History** form where you can rollback the script.

Administrators can run any valid JavaScript that uses the Glide API. The system displays results, information, and error messages at the top of the screen.

ℹ️ **Note:** Running free-form JavaScript can cause system disruption or data loss. Do not run free-form scripts from a production instance.

By default, administrators can access this module without elevating privileges. If you want to require elevated privileges to access this module, set the system property `glide.script_processor.admin` to `security_admin`.

**Installation settings**

Installation settings are global business rules with calculated names. Installation settings are calculated just before a record is displayed and facilitate dynamic determination of access and roles. Installation Settings permit the programmatic determination of a setting.

Installation settings controlling access to fields and records are:

- `CanRead()`
- `CanWrite()`
- `CanCreate()`
- `CanDelete()`

Functions can return true if access is permitted, false if not. No return value uses the permission calculated using roles. The function has access to the current record through the variable current code.
The name of the function checking the permission on a record is formed by prefixing the setting name with the record name:

```
record_nameCanRead()
```

Similarly, the permission on a field in a record is formed by prefixing the function name with the record name, underscore, and field name:

```
record_name_field_nameCanRead()
```

Naming examples:

```
function incidentCanWrite() {} // can user write to this record?
function incident_numberCanWrite() {} // can user write to the number field?
```

This sample business rule restricts the writing of the name field in the sys_dictionary file when the entry exists:

```
// the element name cannot be written unless this is a new record (not yet in database)
function sys_dictionary_nameCanWrite() {
    if (current.isNewRecord())
        return;

    return false;
}
```

**Using DurationCalculator to calculate a due date**

Using the DurationCalculator script include, you can calculate a due date, using either a simple duration or a relative duration based on schedules.

The following script demonstrates how to use the global API `DurationCalculator` to calculate a due date. The first part of the script illustrates how to set a start datetime using the `setStartDateTime()` method and then use the `calcDuration()` method to determine a due date that is "x" amount of continuous time (seconds) from the specified start datetime. The second half of the script illustrates how to use `DurationCalculator` to calculate a due date based on a schedule. Schedules enable you to apply a "filter" on future time, such as only including the days in a work week within the calculation. For example, if you apply a schedule "weekdays" (which only includes Monday through Friday) to your duration calculation, and the start datetime is Friday at 5:00 pm, when you add a duration of two days, your due date would be Tuesday at 5:00 pm. If you did not use a schedule, your due date would be Sunday at 5:00 pm. For additional information on schedules, see Creating and using schedules.

This script can be cut and pasted into the Scripts Background page and run as is. It can also serve as an example for authoring business rules, UI actions, or used any other place that server-side script can be authored.
/**
 * Demonstrate the use of DurationCalculator to compute a due date.
 *
 * You must have a start date and a duration. Then you can compute a
 * due date using the constraints of a schedule.
 */

gs.include('DurationCalculator');
executeSample();

/**
 * Function to house the sample script.
 */
function executeSample(){

    // First we need a DurationCalculator object.
    var dc = new DurationCalculator();

    // --------------- No schedule examples ------------------

    // Simple computation of a due date without using a schedule. Seconds
    // are added to the start date continuously to get to a due date.
    var gdt = new GlideDateTime("2012-05-01 00:00:00");
dc.setStartDateDateTime(gdt);
if(!dc.calcDuration(2*24*3600)){ // 2 days
    gs.log("*** Error calculating duration");
    return;
}
gs.log("calcDuration no schedule: " + dc.getEndDateDateTime()); // "2012-05-03 00:00:00"

    // Start in the middle of the night (2:00 am) and compute a due date 1 hour in the
    // future
    // Without a schedule this yields 3:00 am.
    var gdt = new GlideDateTime("2012-05-03 02:00:00");
dc.setStartDateDateTime(gdt);
if(!dc.calcDuration(3600)){
    gs.log("*** Error calculating duration");
    return;
}
gs.log("Middle of night + 1 hour (no schedule): " + dc.getEndDateDateTime()); // No
scheduled start date, just add 1 hour
// -------------- Add a schedule to the date calculator ---------------------
addSchedule(dc);

// Start in the middle of the night and compute a due date 1 hour in the future.
// Since we start at 2:00 am the computation adds the 1 hour from the start
// of the day, 8:00am to get to 9:00am
var gdt = new GlideDateTime("2012-05-03 02:00:00");
dc.setStartDateTime(gdt);
if(!dc.calcDuration(3600)){
    gs.log("*** Error calculating duration");
    return;
}

gs.log("Middle of night + 1 hour (with 8-5 schedule): " + dc.getEndDateTime()); // 9:00 am

// Start in the afternoon and add hours beyond quitting time. Our schedule says the work day
// ends at 5:00pm, if the duration extends beyond that, we roll over to the next work day.
// In this example we are adding 4 hours to 3:00pm which gives us 10:00 am the next day.
var gdt = new GlideDateTime("2012-05-03 15:00:00");
dc.setStartDateTime(gdt);
if(!dc.calcDuration(4*3600)){
    gs.log("*** Error calculating duration");
    return;
}

gs.log("Afternoon + 4 hour (with 8-5 schedule): " + dc.getEndDateTime()); // 10:00 am.

// This is a demo of adding 2 hours repeatedly and examine the result. This
// is a good way to visualize the result of a due date calculation.
var gdt = new GlideDateTime("2012-05-03 15:00:00");
dc.setStartDateTime(gdt);
for(var i=2; i<24; i+=1){
    if(!dc.calcDuration(i*3600)){
        gs.log("*** Error calculating duration");
        return;
    }
    gs.log("add " + i +" hours gives due date: " + dc.getEndDateTime());
}

// Setting the timezone causes the schedule to be interpreted in the specified timezone.

Using DurationCalculator to compute a simple duration

A simple duration is the number of seconds between two date times. If no schedule is used then this is a simple time date subtraction. If a schedule is used, then the schedule is consulted to remove non-work hours from the computation. Suppose schedule “8-5 weekdays excluding holidays” is used. In this case, the number of work hours from noon Monday to noon Tuesday is nine hours. To compute a simple duration, initialize the global API DurationCalculator and call the calcScheduleDuration() method.

This script demonstrates how to use DurationCalculator to compute a simple duration.
/**
  * Sample script demonstrating use of DurationCalculator to compute simple durations
  *
  */

gs.include('DurationCalculator');
executeSample();

/**
  * Function to house the sample script.
  */
function executeSample()
{
  // First we need a DurationCalculator object.
  var dc = new DurationCalculator();

  // Compute a simple duration without any schedule. The arguments
  // can also be of type GlideDateTime, such as fields from a GlideRecord.
  var dur = dc.calcScheduleDuration("2012-05-01", "2012-05-02");
gs.log("calcScheduleDuration no schedule: " + dur); // 86400 seconds (24 hours)

  // The above sample is useful in limited cases. We almost always want to
  // use some schedule in a duration computation, let's load a schedule.
  addSchedule(dc);

  // Compute a duration using the schedule. The schedule
  // specifies a nine hour work day. The output of this is 32400 seconds, or
  // a nine hour span.
  dur = dc.calcScheduleDuration("2012-05-23 12:00:00","2012-05-24 12:00:00");
gs.log("calcScheduleDuration with schedule: " + dur); // 32400 seconds (9 hours)

  // Compute a duration that spans a weekend and holiday. Even though this
  // spans three days, it only spans 9 work hours based on the schedule.
  dur = dc.calcScheduleDuration("2012-05-25 12:00:00", "2012-05-29 12:00:00");
gs.log("calcScheduleDuration with schedule spanning holiday: " + dur); // 32400 seconds (9 hours)

  // Use the current date time in a calculation. The output of this is
  // dependent on when you run it.
  var now = new Date();
dur = dc.calcScheduleDuration("2012-05-15", new GlideDateTime());
gs.log("calcScheduleDuration with schedule to now: " + dur); // Different on every run.
}
Using relative duration

Relative duration is very similar to simple duration except a piece of script is used to determine what parts of a day to remove from the difference calculation.

This script is stored in table cmn_relative_duration and can be examined by navigating to System Scheduler > Schedules > Relative Durations. There are some example relative duration scripts in the out-of-the-box instance.

A relative duration sys_id is passed to the method calcRelativeDuration() of the global API DurationCalculator class after initialization. When this method is called, the DurationCalculator object is passed to the relative duration script (stored in table cmn_relative_duration) as the variable calculator. So, the relative duration script you write and store in cmn_relative_duration has access to the executing DurationCalculator through the variable calculator.

The following script demonstrates how to use DurationCalculator to calculate a relative duration.

```javascript
/**
 * Sample use of relative duration calculation.
 *
 */

gs.include('DurationCalculator');
executeSample();
```
function executeSample(){

    // First we need a DurationCalculator object. We will also use
    // the out-of-box relative duration "2 bus days by 4pm"
    var dc = new DurationCalculator();
    var relDur = "3bf802c20a0a0b52008e2859cd8abcf2"; // 2 bus days by 4pm if before 10am
    addSchedule(dc);

    // Since our start date is before 10:00am our result is two days from// now at 4:00pm.
    var gdt = new GlideDateTime("2012-05-01 09:00:00");
    dc.setStartDateTime(gdt);
    if(!dc.calcRelativeDuration(relDur)){
        gs.log("*** calcRelativeDuration failed");
        return;
    }
    gs.log("Two days later 4:00pm: "+ dc.getEndDateTime());

    // Since our start date is after 10:00am our result is three days from
    // now at 4:00pm.
    var gdt = new GlideDateTime("2012-05-01 11:00:00");
    dc.setStartDateTime(gdt);
    if(!dc.calcRelativeDuration(relDur)){
        gs.log("*** calcRelativeDuration failed");
        return;
    }
    gs.log("Three days later 4:00pm: "+ dc.getEndDateTime());}

function addSchedule(durationCalculator){
    // Load the "8-5 weekdays excluding holidays" schedule into our duration calculator.
    var scheduleName ="8-5 weekdays excluding holidays";
    var grSched =new GlideRecord('cmn_schedule');
    grSched.addQuery('name', scheduleName);
    grSched.query();
    if(!grSched.next()){  
        gs.log("*** Could not find schedule "+ scheduleName +"'");
    }
}
Querying tables in script
Using methods in the GlideRecord API, you can return all the records in a table, return records based on specific conditions or keywords, or return records from multiple tables with a single query.

⚠️ Note: Before querying a table or an index group, you must configure text indexing and search attributes for one or more tables you want to search. For more information, see Configure a single table for indexing and searching or Configure multiple tables for indexing and searching.

Query tables using the GlideRecord API. For API reference, see GlideRecord - Scoped.

Return records in a table
To query a table, first create a GlideRecord object. To create a GlideRecord, create the following in script:

```javascript
var target = new GlideRecord('incident');
```

Creating a GlideRecord creates a target variable which is a GlideRecord object for the incident table.

To process all records from the incident table, add the following script:

```javascript
target.query(); // Issue the query to the database to get all records
while (target.next()) {
    // add code here to process the incident record
}
```

This script issues the query() to the database. Each call to next() would load the next record for processing.

Return records in a table based on query conditions
Most of the time, you want to retrieve a specific record or a specific set of records, and you have some criteria (query conditions) that define the records you want to obtain. For example, say that you want to obtain all the incident records that have a priority value of 1. Here is the code that would accomplish that.

```javascript
var target = new GlideRecord('incident');
target.addQuery('priority',1);
target.query(); // Issue the query to the database to get relevant records
while (target.next()) {
    // add code here to process the incident record
}
```
Notice that the example script includes `target.addQuery('priority', 1);`. This line indicates that you only want the records where the `priority` field is equal to 1. In general, most queries that you want to perform are equality queries; queries where you want to find records with a field equal to a value. For this reason, you do not need to provide an equality operator. However, let's say you wanted to find all incidents where the `priority` field is greater than 1. In this case, you would provide the operator that you want to apply to the query.

```javascript
var target = new GlideRecord('incident')
target.addQuery('priority','>',1);
target.query(); // Issue the query to the database to get relevant records
while (target.next()) {
    // add code here to process the incident record
}
```

### Return records in a table based on a keyword

Use the '123TEXTQUERY321' reserved value to query a single table. For example, this script returns records from the Incident table that include the 'email' keyword.

```javascript
var now_GR = new GlideRecord('incident');
gr.addQuery('123TEXTQUERY321', 'email');
gr.query();
```

'123TEXTQUERY321' is a reserved value for the `name` parameter in the `addQuery()` method, or you can use it in an encoded query string. For example, instead of `addQuery()`, you can also use `gr.addEncodedQuery('123TEXTQUERY321=<search-term>')`.

### Return records from multiple tables

Use the '123TEXTINDEXGROUP321' reserved value to search for a string in a text index group. A text index group is a group of tables that the system indexes together and searches across. For more information about text index groups, see Configure multiple tables for indexing and searching.

ℹ️ **Note:** To search across multiple tables, they must all use the V4 indexing format.

For example, this script returns records that include the keyword 'email' in the 'portal' index group.

```javascript
var now_GR = new GlideRecord('kb_knowledge');
gr.addQuery('123TEXTQUERY321', 'email');
```
You would then create a query for each table in the index group and merge the results.

'123TEXTINDEXGROUP321' is a reserved value for the name parameter in the addQuery() method, or you can use it in encoded query string. For example, instead of addQuery(), you can use gr.addEncodedQuery('123TEXTINDEXGROUP321=<index-group>').

**Available JavaScript operators**

Describes the operators that can be used within an addQuery() request.

<table>
<thead>
<tr>
<th>Field</th>
<th>Definition</th>
<th>addQuery</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>Field must be equal to value supplied.</td>
<td>addQuery('priority', '=', 1);</td>
</tr>
<tr>
<td>&gt;</td>
<td>Field must be greater than value supplied.</td>
<td>addQuery('priority', '&gt;', 1);</td>
</tr>
<tr>
<td>&lt;</td>
<td>Field must be less than value supplied.</td>
<td>addQuery('priority', '&lt;', 3);</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Field must be equal or greater than value supplied.</td>
<td>addQuery('priority', '&gt;=', 1);</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Field must be equal or less than value supplied.</td>
<td>addQuery('priority', '&lt;=', 3);</td>
</tr>
<tr>
<td>!=</td>
<td>Field must not equal the value supplied.</td>
<td>addQuery('priority', '!=', 1);</td>
</tr>
<tr>
<td>STARTSWITH</td>
<td>Field must start with the value supplied. The example shown on the right returns all records where the short_description field starts with the text Error.</td>
<td>addQuery('short_description', 'STARTSWITH', 'Error');</td>
</tr>
<tr>
<td>CONTAINS</td>
<td>Field must contain the value supplied somewhere in the text. The example shown on the right returns all records where the short_description field contains the text Error anywhere in the field.</td>
<td>addQuery('short_description', 'CONTAINS', 'Error');</td>
</tr>
<tr>
<td>Field</td>
<td>Definition</td>
<td>addQuery</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IN</td>
<td>Takes a map of values that allows commas, and gathers a collection of records that meet some other requirement. Behaves as: <code>Select * from &lt;table&gt; where short_description IN ('Error', 'Success', 'Failure')</code>, which is identical to <code>Select * from &lt;table&gt; where short_description='Error'</code>. For example, to query all variable values that belong to a specific Activity, use the <code>IN</code> clause, and store their sys_ids in a map, or comma-separated list. Then query the variable value table and supply this list of sys_ids.</td>
<td><code>addQuery('short_description', 'IN', 'Error,Success,Failure');</code></td>
</tr>
<tr>
<td>ENDSWITH</td>
<td>Field must terminate with the value supplied. The example shown on the right returns all records where the <code>short_description</code> field ends with text Error.</td>
<td><code>addQuery('short_description', 'ENDSWITH', 'Error');</code></td>
</tr>
<tr>
<td>DOES NOT CONTAIN</td>
<td>Selects records that do NOT match the pattern in the field. This operator does not retrieve empty fields. For empty values, use the operators &quot;is empty&quot; or &quot;is not empty.&quot; The example shown on the right returns all records where the <code>short_description</code> field does not have the word &quot;Error.&quot;</td>
<td><code>addQuery('short_description', 'DOES NOT CONTAIN', 'Error');</code></td>
</tr>
<tr>
<td>NOT IN</td>
<td>Takes a map of values that allows commas, and gathers a collection of records that meet some other requirement. Behaves as: <code>Select * from &lt;table&gt; where short_description NOT IN ('Error')</code>.</td>
<td><code>addQuery('short_description', 'NOT IN', 'Error,Success,Failure');</code></td>
</tr>
<tr>
<td>INSTANCEOF</td>
<td>Special operator that retrieves only records of a specified &quot;class&quot; for extended tables. The code example on the right, shows how to retrieve all <code>cmdb_ci_computer</code>.</td>
<td><code>addQuery('sys_class_name', 'INSTANCEOF', 'cmdb_ci_computer');</code></td>
</tr>
</tbody>
</table>
Available JavaScript Operators (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Definition</th>
<th>addQuery</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>configuration items that are classified as computers.</td>
<td></td>
</tr>
</tbody>
</table>

For additional information on the operators that are available for filters and queries, see Operators available for filters and queries.

There are also some special methods that you can use to search for data that is NULL or NOT NULL. To search for all incidents where the `short_description` field has not been supplied (is null), use the following query:

```javascript
var target = new GlideRecord('incident');
target.addNullQuery('short_description');
target.query(); // Issue the query to the database to get all records
while (target.next()) {
    // add code here to process the incident record
}
```

To find all incidents in which a `short_description` has been supplied, use the following query:

```javascript
var target = new GlideRecord('incident');
target.addNotNullQuery('short_description');
target.query(); // Issue the query to the database to get all records
while (target.next()) {
    // add code here to process the incident record
}
```

For more information on the GlideRecord API and its available methods, see GlideRecord.

GlideRecord query examples

These examples demonstrate how to perform various GlideRecord queries.

```javascript
query

var rec = new GlideRecord('incident');
rec.query();
while(rec.next()) {
    gs.print(rec.number + ' exists');
}
```
**update**

```javascript
var rec = new GlideRecord('incident');
rec.addQuery('active',true);
rec.query();
while(rec.next()) {
    rec.active = false;
    gs.print('Active incident ' + rec.number + ' closed');
    rec.update();
}
```

**insert**

```javascript
var rec = new GlideRecord('incident');
rec.initialize();
rec.short_description = 'Network problem';
rec.caller_id.setDisplayValue('Joe Employee');
rec.insert();
```

**delete**

```javascript
var rec = new GlideRecord('incident');
rec.addQuery('active',false);
rec.query();
while(rec.next()) {
    gs.print('Inactive incident ' + rec.number + ' deleted');
    rec.deleteRecord();
}
```

**Querying Service Catalog Tables**

You cannot directly query the variables of the Service Catalog Request Item table [sc_req_item]. Instead, query the Variable Ownership table, [sc_item_option_mtom], by adding two queries, one for the variable name and another for the value. The query returns the many-to-many relationship, which you can dot-walk to the requested item. The following example finds the request items that have the variable `item_name` with a value of `item_value` and displays the request item numbers:

```javascript
var now_GR = new GlideRecord('sc_item_option_mtom');
gr.addQuery('sc_item_option.item_option_new.name','item_name');
gr.addQuery('sc_item_option.value','item_value');
gr.query();
while(gr.next()) {
    gs.addInfoMessage(gr.request_item.number); }```

For additional information see GlideRecord.
Running order guides automatically

Service catalog order guides allow customers to make a single service catalog request that can generate several ordered items. Administrators can configure order guides to run automatically, from a workflow or a script to generate a set of ordered items without manually submitting a service catalog request. Administrators can also review and reprocess the order guide failures.

For example, an onboarding workflow for a new employee can run an order guide to automatically order items for that employee.

Running order guides from scripts

Running order guides with a server-side script is more complex than using workflows, but it allows more flexibility and can be used in non-workflow situations.

For example, you can use order guide scripts with UI actions or server-side business rules.

⚠️ Note: When order guides run automatically, order guide UI policies are not enforced. Also, options in the Choose Options screen cannot be selected, so make sure that order guide rules define sensible defaults for these options to avoid processing failures.

Use the `SNC.ScriptableOrderGuide` Java class to run order guides with a script.

Use the `SNC.ScriptableOrderGuide(String orderGuideId)` constructor to create a new `ScriptableOrderGuide` object.

Method summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>process(String json)</code></td>
<td>boolean</td>
<td>Runs the order guide using the JSON encoded string parameter as the input for the order guide. Returns <code>true</code> or <code>false</code> depending on whether processing was successful or not.</td>
</tr>
</tbody>
</table>

⚠️ Note: Both `opened_by` and `requested_for` parameters must be passed to the order guide, and both must have valid user record `sys_id` values.
<table>
<thead>
<tr>
<th>Method</th>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reprocess(GlideRecord failure)</td>
<td>boolean</td>
<td>Runs the order guide again using the JSON encoded string parameter stored in the failure GlideRecord.</td>
</tr>
<tr>
<td>getMessage()</td>
<td>String</td>
<td>Retrieves the message populated after processing or reprocessing.</td>
</tr>
<tr>
<td>getRequest()</td>
<td>GlideRecord</td>
<td>Retrieves the request GlideRecord.</td>
</tr>
<tr>
<td>getFailure()</td>
<td>GlideRecord</td>
<td>Retrieves the failure GlideRecord from the Scriptable Order Guide Failures [sc_script_order_guide_failure] table.</td>
</tr>
</tbody>
</table>

**Script example**

This script processes an order guide called *IT Onboarding SOG*.

```java
// Creating the object to later be JSON encoded
var json = {
    "opened_by": "62826bf03710200044e0bfc8bcbe5df1", "requested_for": "06826bf03710200044e0bfc8bcbe5d8a", "department": "221f3db5c611228409f4becd3039cc9"
};

var now_GR = new GlideRecord("sc_cat_item_guide");
if (gr.get("name","IT Onboarding SOG")) {
    var sog = new SNC.ScriptableOrderGuide(gr.getValue("sys_id"));
    var result = sog.process(new JSON().encode(json));
    if (!result)
        gs.log("Processing the scriptable order guide failed with message: " + sog.getMessage());
    else {
        var request = sog.getRequest();
        gs.log("Request created - " + request.sys_id); 
    }
}
Running order guides from workflows

Running an order guide from a workflow is suitable if you include order guides as part of a broader workflow-based process.

For example, an activity within an onboarding workflow for a new employee can automatically run an order guide to order items for that employee.

Note: When order guides run automatically, order guide UI policies are not enforced. Also, options in the Choose Options screen cannot be selected, so make sure that order guide rules define sensible defaults for these options to avoid processing failures.

To run order guides from a workflow, use the **Scriptable Order Guide** workflow activity.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Order Guide</td>
<td>The name of the order guide that this activity processes. For example, <strong>Example Employee Onboarding IT</strong>.</td>
</tr>
<tr>
<td>Script</td>
<td>A script passing information to the order guide. This information is sent as a JSON encoded string parameter assigned to the answer variable. The script must meet these requirements:</td>
</tr>
<tr>
<td></td>
<td>- The names of the variables in the script must match the names used within the order guide. For example, if the order guide uses a <em>department</em> variable in a rule condition, the script must also pass a <em>department</em> parameter.</td>
</tr>
<tr>
<td></td>
<td>- Both <em>opened_by</em> and <em>requested_for</em> parameters must be passed to the order guide, and both must have valid user record sys_id values.</td>
</tr>
</tbody>
</table>

**Results**

- **Success**: the activity successfully processed the order guide. This does not mean a request was created. If a request was created, the request sys_id is added to the workflow scratchpad under the *sc_request* variable.

- **Failure**: while processing the order guide a failure occurred, creating a failure record. If the processing fails, you can view and edit the failure record.
Workflow example

The Example Employee Onboarding IT Workflow workflow uses this example to generate IT catalog items for a new employee as part of an onboarding process.

The activity uses this script to:

1. Take a JSON string generated previously from the HR change record.
2. Append the mandatory opened_by and requested_for parameters to that string.
3. Submit the new string for processing by the order guide.

```javascript
var parameters = new JSON().decode(current.payload);

// Need to amend the json object to include additional values.
parameters.opened_by = current.opened_by + "";
parameters.requested_for = current.opened_for + "";

answer = new JSON().encode(parameters);
```

View order guide failures

Order guide processing can fail, for example if the order guide being run does not exist. When a failure occurs during the order guide processing, the Scriptable Order Guide Failures submodule allows you to review and reprocess the failures. A record is created for each failure and once you fix the errors that caused the initial failure, you can reprocess the failed order guides.

About this task

If a failure occurs, a failure record is created in the Scriptable Order Guide Failures [sc_script_order_guide_failure] table.

To view details of a failure, navigate to Service Catalog > Catalog Administration > Scriptable Order Guide Failures, then open a failure record.

Reprocessing Failures

If you have fixed the error that caused the initial failure, you can reprocess failed order guides.

Procedure

1. Navigate to Service Catalog > Catalog Administration > Scriptable Order Guide Failures.
2. Open the failure record.
3. Click the Reprocess related link.
To reprocess one or more failures:

a. Navigate to **Service Catalog > Catalog Administration > Scriptable Order Guide Failures**.
b. Select the check box beside one or more records to reprocess.
c. Select **Reprocess** from the **Actions** choice list.

**Scriptable assignment of execution plans**

Each catalog item has an associated execution plan, used whenever an item of that type is ordered; if no plan is specified, the default plan is used. This default is effective for most organizations, but your execution plan may need to vary based on additional criteria.

For example, in the base system service catalog, a request for a new PC always uses the PC Delivery Plan. However, this plan may need to vary for unusual circumstances - such as when a requester is working from home, at a remote location.

To provide this flexibility, you can use a script to override the default execution plan on a specific catalog item.

**Limitations during script execution**

Execution plan scripts have limitations that need to be considered during their implementation.

While the execution plan script runs:

- You cannot interact with any catalog tasks as catalog tasks are only created after the execution plan is selected.
- Some fields such as total delivery time and due date are not yet calculated, although the request itself is available within the script via `current.request()`.
- Approvals have not yet been generated.

**Writing the scripts**

Follow these guidelines when writing execution plan scripts.

Execution plan scripts can access the same global variables and other functions as in any other server side execution plan.

- `current` is the currently-requested catalog item, `sc_req_item`.
- `current.delivery_plan()` is the assigned execution plan for this catalog item.
The evaluated value from the script is used as the sys_id of the execution plan.

Simple example:

```javascript
current.delivery_plan.setDisplayValue('PC Delivery Plan')
```

If an invalid value is returned, such as undefined or not found, then the existing assigned value is used.

More complex example:

```javascript
getexecutionplan();
function getexecutionplan() {
  var location = current.request.requested_for.location.getDisplayValue();
  // if we're in Atlanta
  if (location == 'Atlanta') {
    // use the remote pc delivery plan instead of the normal one
    var remote_plan = new GlideRecord('sc_cat_item_delivery_plan');
    remote_plan.addQuery('name', 'Remote PC Delivery Plan');
    remote_plan.query();
    remote_plan.next();
    current.delivery_plan = remote_plan.sys_id;
    return remote_plan_sys_id;
  }
  return current_delivery_plan;
}
```

In this example, any time a request is for a user in Atlanta, ServiceNow uses the Remote PC Delivery Plan. Otherwise, the execution plan is not overridden and ServiceNow uses the catalog item’s normal execution plan, the PC Delivery Plan.

Add a script to a catalog item

You can add a script to a catalog item so that the script runs each time a user requests that item.

Procedure

1. Navigate to Service Catalog > Maintain Items.
2. Select the relevant catalog item to which you wish to add the script.
3. Configure the catalog item form to add the execution plan script field, often named Delivery Plan Script.
4. Fill in the script details.
5. Update the item form with your changes.

Results
The script runs each time that item is requested, selecting the execution plan to run with that item.

Use a script to approve an execution plan
You can use an approval rule script to approve an execution plan.
**Procedure**

1. Retrieve an approval execution plan task.
2. View the **Approval Script** field.
3. Fill in an approval script using the same syntax and rules you would use on an approval rule.

**Example:**
For example, in the script below, the requester’s manager is the approver.

![Approval Script Example](image)

**Scriptable service catalog variables**

You can use scripting to reference any request item variable from a table in scoped and non-scoped environment.

An example of a variable reference follows.

```javascript
current.variables.<variable_name>
```

Where `current` refers to the current record, and `<variable_name>` is the name of your variable.

**Note:** In order to reference a variable from JavaScript, it must have a name.
When a variable is part of a variable set, you can reference it as `current.variables.<variable_name>` or `current.variables.<variable_set_name>.<variable_name>`.

Variable set is also a first-class citizen in Service Catalog. Like variables, a variable set has read, write, and create roles. If roles are provided for a variable set, the roles are applicable for the variables within the set. Roles of an individual variable are overridden by the roles of the variable set.

**Print a variable**

```javascript
var original = current.variables.original_number;
gs.print(original);
```

**Set a variable**

```javascript
current.variables.name = "Auto-Generated:" + current.variables.asset_tag;
```

**Create an inventory item with fields set from variables**

```javascript
doCreation();

function doCreation ( ) {
  var create = current.variables.create_item;
  if (create == 'true') { // we want to create an asset
    var computer = new GlideRecord('cmdb_ci_computer');
    computer.initialize();
    computer.asset_tag = current.variables.asset_tag;
    computer.serial_number = current.variables.serial_number;
    computer.name = current.variables.name;
    computer.manufacturer = current.variables.company;
    computer.insert();
  }
}
```

**Get GlideElementVariable of variables and variable sets associated with a GlideRecord**

```javascript
now_GR.variables
```

**Get the name value pair of variables associated with a GlideRecord**

```javascript
now_GR.variables.getVariableValue();
```

**Get a list of GlideElementVariable for variables within a task record**

```javascript
now_GR.variables.getElements();
```
Get a list of GlideElementVariable for variables (including multi-row variable set) within a task record

```javascript
now_GR.variables.getElements(true);
```

### APIs for GlideElementVariable

- `now_GR.variables.<var_name>.isMultiRow()`: Get whether the GlideElementVariable is a multi-row variable set or a variable.
- `now_GR.variables.<var_name>.getQuestion()`: Get the Question object for a variable. Applicable only for a variable (isMultiRow() is false) and not for a multi-row variable set.
- `now_GR.variables.<var_name>.getLabel()`: Get the label of the GlideElementVariable. For a variable, the label of the variable is returned. For multi-row variable set, the title of the variable set is returned.
- `now_GR.variables.<var_name>.canRead()`: Get whether the user can view a variable or multi-row variable set.
- `now_GR.variables.<var_name>.canWrite()`: Get whether the user can edit a variable or multi-row variable set.
- `now_GR.variables.<var_name>.getDecryptedValue()`: Get the decrypted value for a masked variable. Applicable only for a masked variable.
- `now_GR.variables.<var_name>.getRows()`: Get the list of row objects for a multi-row variable set. Applicable only for a multi-row variable set (isMultiRow() is true).
- `now_GR.variables.<var_name>.getRowCount()`: Get the number of rows for multi-row variable set. Applicable only for a multi-row variable set (isMultiRow() is true).

### Example to access variables of GlideRecord for the Task table

```javascript
var now_GR = new GlideRecord('sc_req_item');
if (now_GR.get('635a1f5387320300e0ef0cf888cb0b73')) {
    var variables = now_GR.variables.getElements();
    for (var i=0;i<variables.length;i++) {
        var question = variables[i].getQuestion();
        gs.log(question.getLabel() + "":" + question.getValue())
    }
}
```
Example to access a multi-row variable set of GlideRecord for the Task table

```javascript
var now_GR = new GlideRecord('sc_req_item');
now_GR.get('02c38dcd87013300e0ef0cf888cb0bb2');

var vars = now_GR.variables.getElements(true);

for (var i=0; i<vars.length; i++) {
    var now_V = vars[i];
    if (now_V.isMultiRow()) {
        var rows = now_V.getRows();
        for (var j=0; j<now_V.getRowCount(); j++) {
            var row = rows[j];
            var cells = row.getCells();
            for (var k=0; k<cells.length; k++) {
                var cell = cells[k];
                gs.info(cell.getLabel() + ':' + cell.getCellDisplayValue());
            }
        }
    }
}
```

### Multi-row variable set

<table>
<thead>
<tr>
<th>Operation</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table operations</td>
<td></td>
</tr>
<tr>
<td>Return JSON array value as String</td>
<td><code>now_GR.variables.table_var</code></td>
</tr>
<tr>
<td>Set value of a multi-row variable set</td>
<td><code>now_GR.variables.table_var = &lt;val&gt;</code></td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: An array of ordered (key, value) pairs is also applicable as input.</td>
</tr>
<tr>
<td>Get value of column, var1, of a multi-row variable set</td>
<td><code>now_GR.variables.table_var.var1</code></td>
</tr>
<tr>
<td>Set value of a variable set, var1</td>
<td><code>now_GR.variables.table_var.var1 = &lt;val&gt;</code></td>
</tr>
</tbody>
</table>
## Multi-row variable set (continued)

<table>
<thead>
<tr>
<th>Operation</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Operation</strong></td>
<td><strong>Usage</strong></td>
</tr>
<tr>
<td>&lt;note&gt;<strong>Note:</strong> An array of ordered (key, value) pairs is also applicable as input.&lt;/note&gt;</td>
<td></td>
</tr>
<tr>
<td>Row operations</td>
<td></td>
</tr>
<tr>
<td>Get the current row count</td>
<td><code>now_GR.variables.table_var.getRowCount()</code></td>
</tr>
<tr>
<td>Returns the row specified by the variable &quot;i&quot; - <code>getRow(&lt;int&gt; i)</code></td>
<td><code>var row = now_GR.variables.table_var.getRow(&lt;int&gt; i);</code></td>
</tr>
<tr>
<td>Get the cell value for a question column mapped to <code>&lt;var_name&gt;</code></td>
<td><code>row.&lt;var_name&gt;</code></td>
</tr>
<tr>
<td>Set the cell value for a question column mapped to <code>&lt;var_name&gt;</code></td>
<td><code>row.setCellValue('&lt;var_name&gt;', value)</code></td>
</tr>
<tr>
<td>Set the cell value for a question column mapped to <code>&lt;var_name&gt;</code></td>
<td><code>row.&lt;var_name&gt; = value</code></td>
</tr>
<tr>
<td>Add an empty row at the end of the table and return a scriptable object</td>
<td><code>var row = now_GR.variables.table_var.addRow()</code></td>
</tr>
<tr>
<td>Delete a row</td>
<td><code>row.deleteRow()</code></td>
</tr>
</tbody>
</table>

### Notes and limitations

1. You can only set a variable in a before business rule. Variables set in an after rule are not written to the database.

2. There is nothing in place to prevent namespace collision with variables. Creating two variables named computer_speed would result in only one of them showing up; the second one would overwrite the first one.

3. Date/time variables use the same time zone formatting and storage rules as all other dates in the system. They are stored internally in GMT, but translated into the user's local time zone and format for display.
Setting a GlideRecord variable to null

GlideRecord variables (including current) are initially null in the database. Setting these back to an empty string, a space, or the JavaScript null value will not result in a return to this initial state.

⚠️ Note: This functionality requires a knowledge of JavaScript.

⚠️ Note: Functionality described here requires the Admin role.

To set it back to the initial state, simply set the value to "NULL". Note that the update() function does not run on the current object but rather on the record. The object displays the initial value until it is called again from the record.

Example 1

```javascript
var gr1 = new GlideRecord('incident');
gr1.query();
while(gr1.next()) {
    gr1.priority = "NULL";
    gr1.update();
}
```

Example 2 (Business Rule)

```javascript
current.u_affected_value = 'NULL';
current.update();
```

Wizard scripts

You can create scripts to implement advanced custom functionality using wizards.

Use wizard scripts in record generator panels, transitions, and UI policies.

⚠️ Note: The System Wizards application is not active by default.

To reference a wizard variable in a script, use the format `wizard.<name>`, where <name> is the value in the Name field of the variable definition.

Wizard script examples

These examples demonstrate scripts that use wizard variables.

Example 1

```javascript
//Find a user in the sys_user table with the wizard variable 'EmpName'
function getUser(){
    var gu = new GlideRecord('sys_user');
```
gu.addQuery('sys_id', wizard.EmpName);
gu.query();
if(gu.next()){
    gs.addInfoMessage('Found user ' + gu.name)
}

Example 2

//Loop through items in a wizard list collector with variable name astList
function removeAssets() {
    var items = wizard.astList.toString();
    items = items.split(',');
    for (var i = 0; i < items.length; i++) {
        //got the asset id
        var sys_id = items[i];
    }
}

Example 3

//Set the url on wizard completion - user will be redirected to this location
var uri = ('sys_user_list.do?sysparm_query=sys_id=' + wizard.EmpName);
wizard.redirect = uri;

Wizard scripts on record generators

Use wizard scripts in record generator panels to create records in any table, including on more than one table.
Procedure

1. In the Table field, select Global.
2. Enter a script in the Script field. Configure the form to add the field, if necessary.

Wizard UI policy and client scripts

Create dynamic effects in wizards with UI policies and client scripts. For example, get or set variable values, hide or display variables, make variables mandatory, or validate values.

UI policies apply effects based on conditions constructed with a condition builder. Client scripts accomplish more advanced functionality, but require scripting knowledge. Since UI policies do not require scripting, they are less likely to need maintenance after system updates.

ℹ️ Note: The System Wizards application is not active by default.

Schedule Pages

A schedule page is a record that contains a collection of scripts that allow for custom generation of a calendar or timeline display.
Creation of timeline schedule pages requires understanding of the page/event flow and the ability to write client and server side JavaScript.

**Schedule pages form**

To access schedule pages, navigate to **System Scheduler > Schedules > Schedule Pages**.

The form provides the following fields, depending upon the View Type selected:

<table>
<thead>
<tr>
<th>Field</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>String</td>
<td>General name that is used to identify the current schedule page.</td>
</tr>
<tr>
<td>Schedule type</td>
<td>String</td>
<td>The schedule type is a string that is used to uniquely identify the schedule page via the &quot;sysparm_page_schedule_type&quot; URI parameter. For example, a schedule page could be accessed as follows: <code>/show_schedule_page.do?sysparm_page_schedule_type=gantt_chart&amp;sysparm_timeline_task_id=d530bf907f0000015ce594fd929cf6a4</code> Alternatively, the schedule page can also be accessed by setting the &quot;sysparm_page_sys_id&quot; URI parameter to that of the unique 32 character hexadecimal system identifier of the schedule page.</td>
</tr>
<tr>
<td>View Type</td>
<td>Choice</td>
<td>Each view type displays different field combinations. There are two options:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Calendars</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Timelines</td>
</tr>
<tr>
<td>Description</td>
<td>String</td>
<td>General description that provides additional information about the current schedule page as necessary.</td>
</tr>
<tr>
<td>Init function name</td>
<td>String</td>
<td>Note: This functionality is only used by Calendar type schedule pages. The init function name specifies the name of the JavaScript function to call inside the Client script function for calendar type schedule pages.</td>
</tr>
<tr>
<td>HTML</td>
<td>String</td>
<td>Note: This functionality is only used by Calendar type schedule pages. The HTML field is a scriptable section that is parsed by Jelly and injected into the display page prior to the rest of the calendar. It can be used to pass in variables from the server and define extra fields as necessary.</td>
</tr>
<tr>
<td>Client script</td>
<td>String</td>
<td>The client script is a scriptable section that allows for configuring options of the schedule page display. The API is different depending on the schedule page view type and is discussed below.</td>
</tr>
</tbody>
</table>
Schedule pages form (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Field Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server AJAX processor</td>
<td>String</td>
<td>Note: This functionality is only used by Calendar type schedule pages. The Server AJAX processor is specific to calendar type schedule pages. It is used to return a set of schedule items and spans to be displayed.</td>
</tr>
</tbody>
</table>

Timeline schedule pages

A Timeline Schedule Page is a specific record that contains configuration information for displaying time based points and spans in a "timeline" like fashion.

The timeline schedule page references a script include that extends from AbstractTimelineSchedulePage to perform dynamic modification to the timeline based on different events and conditions. Both the schedule page and the script include for timeline generation allow for extreme customization and their corresponding application programming interface (API) is documented below.

The following diagram shows the series of events that occur when a timeline schedule page is accessed. Once the timeline has been loaded, all subsequent events, such as events resulting from timeline interaction (e.g. moving a timeline span), follow the same logic flow shown in the gray event box.
Timeline Flow

Client browser accesses a schedule page. The request is sent to the server.

http://instance.service-now.com/show_schedule_page.do?sysparm_page_schedule_type=mntb_client4sysparm_timeline_task_id-0f030b6d971f3b6f00160e064d0f6046

The server interprets the schedule page HTTP request and obtains information about the specific schedule page from either of the following URI parameters:

sysparm_page_sys_id
or
sysparm_page_schedule_type

The server returns an HTTP response that contains the client script information from the specified schedule page.

The client browser immediately parses the Client script section of the schedule page upon loading of the page.
- Set configuration and display options
- Register event listeners

Event: getItems

The client timeline makes an AJAX request to the corresponding Script Include for the event registered with "getItems" to retrieve the set of items and spans to display on the timeline.

The server receives the request and executes the getItems code block inside the specified Script Include (which is an instance of the AbstractTimelineSchedulePage class). The server returns an XML document with TimelineItem objects.

The client receives the AJAX response with the specified TimelineItem objects and appropriately displays them on the screen.

Applications that use schedule pages to generate timelines

- Project Management
- Maintenance Schedules
- Group On-Call Rotation
- Field Service Management

Timeline schedule page example

The following example demonstrates how to create a timeline schedule page with corresponding script include utilizing a majority of the API described above.

For this example we are going to create an Incident Summary Timeline for a project support manager to visualize all of the new incidents. All new incidents
should be displayed as single points where the priority of the incident is distinguished by a different point icon. Additionally, all closed incidents should be displayed on the timeline in a separate group that shows the duration of the incident before it was closed. Since the Project Manager wants to be able to easily close new items that are resolved without using any form lists, we will handle the vertical move event allowing the new incidents to be dragged into the closed incident group or items within.

**Schedule Page**
Create a new schedule page with the following properties:

- **Name:** Hardware Incidents
- **Schedule type:** incident_timeline
- **View Type:** Timeline
- **Client Script:**

```javascript
// Set our page configuration
glideTimeline.setReadOnly(false);
glideTimeline.showLeftPane(true);
glideTimeline.showLeftPaneAsTree(true);
glideTimeline.showTimelineText(true);
glideTimeline.showDependencyLines(false);
glideTimeline.groupByParent(true);
glideTimeline.setDefaultPointIconClass('milestone');

// We will define what items to display and provide a custom event handler for moving new items to the closed state
glideTimeline.registerEvent('getItems', 'IncidentTimelineScriptInclude');
glideTimeline.registerEvent('elementMoveY', 'IncidentTimelineScriptInclude');
```

**Script Include**
Now that the schedule page has been created we need to generate a matching script include for the events that were registered. Create a new script include with the following properties:

- **Name:** IncidentTimelineScriptInclude
- **Active:** Checked
- **Client callable:** Checked
- **Script:**

```javascript
// Class Imports
```
var IncidentTimelineScriptInclude = Class.create();
IncidentTimelineScriptInclude.prototype =
Object.extendsObject(AbstractTimelineSchedulePage, {

getItems:function() {
  // Specify the page title
  this.setPageTitle('My Custom Incident Summary Timeline');

  var groupNew = new GlideTimelineItem('new');
  groupNew.setLeftLabelText('New Incidents');
  groupNew.setImage('../images/icons/all.gifx');
  groupNew.setTextBold(true);
  this.add(groupNew);

  var groupClosed = new GlideTimelineItem('closed');
  groupClosed.setLeftLabelText('Closed Incidents');
  groupClosed.setImage('../images/icons/all.gifx');
  groupClosed.setTextBold(true);
  groupClosed.setIsDroppable(true);
  this.add(groupClosed);

  // This allows us to drag an open incident onto the closed group row.
  this.add(groupClosed);

  // Get all the incidents and let's add only the new/closed ones appropriately
  var now_GR = new GlideRecord('incident');
  gr.query();
  while(gr.next()) {
    // Only loop through new/closed incidents
    if(gr.incident_state != '1' && gr.incident_state != '7') continue;

    // Ok, we have a new/closed incident. Create the item and the span first.
    var item = new GlideTimelineItem(gr.getTableName(), gr.sys_id);
    var span = item.createTimelineSpan(gr.getTableName(), gr.sys_id);

    // Specific properties for a new incident
    if(gr.incident_state == '1') { // New
      item.setParent(groupNew.getSysId());
      item.setImage('../images/icons/open.gifx');
      span.setTimeSpan(gr.getElement('opened_at').getGlideObject().getNumericValue(),
        gr.getElement('opened_at').getGlideObject().getNumericValue());

      // We'll show different colors based upon the priorities only for new incidents
      switch(gr.getElement('priority').toString()) {

      }
    }
  }

});
case '1': span.setPointIconClass('red_circle'); break;
case '2': span.setPointIconClass('red_square'); break;
case '3': span.setPointIconClass('blue_circle'); break;
case '4': span.setPointIconClass('blue_square'); break;
case '5': span.setPointIconClass('sepia_circle'); break;
default: // Otherwise, the default point icon class will be used (Milestone) 
}
}

// Specific properties for a closed incident
else if(gr.incident_state == '7') {
    item.setParent(groupClosed.getSysId());
    item.setImage('../images/icons/closed.gifx');
    span.setTimeSpan(gr.getElement('opened_at').getGlideObject().getNumericValue(),
    gr.getElement('closed_at').getGlideObject().getNumericValue()); 
}

    // Common item properties
    item.setLeftLabelText(gr.short_description);

    // Common span properties
    span.setSpanText(gr.short_description);
    span.setTooltip('<strong>' + GlideStringUtil.escapeHTML(gr.short_description) +
    '</strong><br>' + gr.number);
    span.setAllowXMove(false);
    span.setAllowYMove(gr.canWrite() ? true:false);
    span.setAllowYMovePredecessor(false);
    span.setAllowXDragLeft(false);
    span.setAllowXDragRight(false);

    // Now we add the actual item
    this.add(item);
}

ELEMENT_MOVE_Y

/**
 * This is one of the AbstractTimelineSchedulePage event handler methods that corresponds
 * to a vertical
 * move. The arguments for this function are defined in the API section of the event
 * handler methods.
 */
elementMoveY: function(spanId, itemId, newItemId) {
// Get information about the current incident
var now_GR = new GlideRecord('incident');
gr.addQuery('sys_id', spanId);
gr.query();
if(!gr.next())
    return this.setStatusError('Error', 'Unable to lookup the current incident.');

// Only allow the new incidents to have their state adjusted.
if(gr.incident_state != '1')
    return this.setStatusError('Error', 'Only new incidents can have their state adjusted.'TOTYPE

// Get information about the dropped GlideTimelineItem. If it was dropped in an item on
the "New Incidents"
// group let's do nothing. If it was dropped in the "Closed Incidents" then let's
adjust the state automatically.
var grDropped = new GlideRecord('incident');
grDropped.addQuery('sys_id', newItemId);
grDropped.query();
if(!grDropped.next() || grDropped.incident_state == '7') {
    // This means the dropped item was either the 'Closed Incidents' group (which has no
record or sys_id) or an
    // existing incident that is closed. The 'New Incidents' also has no sys_id;
however, the default behavior for
    // items without a sysId is to be non-droppable. This is why we explicitly denoted
the 'Closed Incidents' to
    // be marked as "droppable".

    // Return a dialog prompt
    this.setStatusPrompt('Confirm', 'Are you sure you want to close: ' +
    '<div style="margin:10px 0 10px 14px;padding:4px;background-color:#EBEBEB;">\<strong>\</strong><\div></div>',
    GlideStringUtil.escapeHTML(gr.short_description) +
    '<\strong><br/>\<div class="font_smaller">' + now_GR. number +
    '</div></div>',
    'this._elementMoveYHandler_DoClose', // This function is for when the OK
button is clicked.
    'this._elementMoveYHandler_DoNothing', // This function is for when the
Cancel button is clicked.
    'this._elementMoveYHandler_DoNothing'); // This function is for when the
Close button is clicked.
}
Screenshots / Results

1. Navigate to:

http://[YOURINSTANCE]:8080/show_schedule_page.do?
sysparm_page_schedule_type=incident_timeline

Notice the bold text is the value of the schedule page Schedule type field.

2. The page displays a timeline as specified by the schedule page and script include created. A link to this page can be created and placed as a module or UI action as necessary.
3. Attempting to move a closed incident anywhere displays the expected error message.

4. Moving the incident: I need more memory displays the following confirmation box.

5. Clicking the **Cancel** button closes the overlay. Clicking the **OK** button actually updates the incident_state of the record and then displays the following success box.
6. After clicking **OK**, it is clear the incident is now listed in the **Closed Incidents** group.

**XMLDocument script object**

A JavaScript object wrapper for parsing and extracting XML data from an XML document (String).

Use this Javascript class to instantiate an object from an XML string, usually a return value from a Web Service invocation, or the XML payload of ECC Queue. Using the XMLDocument object in a Javascript business rule lets you query values from the XML elements and attributes directly.

**Constructor**

The constructor of a script object creates a new instance of the object to be used.

```javascript
var xmlString = "<test>" +
    "  <one>" +
```
To perform XML parsing of an XML string that is name space qualified, specify "true" for the second argument for the XMLDocument constructor. The following is an example of parsing and XML string that contains name space qualification of its elements.

```javascript
var xmlString = "<bk:book xmlns:bk='urn:loc.gov:books'
         xmlns:isbn='urn:ISBN:0-395-36341-6'>" +
    "<bk:title>Cheaper by the Dozen</bk:title>" +
    "<isbn:number>1568491379</isbn:number>" +
    "</bk:book>";

var xmldoc = new XMLDocument(xmlString, true); // XML document is name space aware
```

### Locating nodes and elements

Now that we have the XMLDocument object, we can call the following APIs to locate nodes and elements of the XML document, as well as extract text from it directly. The query syntax for locating nodes and attributes is based on XPath.

???? Note: XMP parsing with this object is not namespace aware, this means that if you are locating a node name with namespace in it eg. "<names:myelement> ...", the XPath search string would be "///myelement"

The following are examples of locating a node by its XPath and getting the text value out of the resulting node.

```javascript
var str = xmldoc.getNodeText("/two"); // returns the first occurrence of the node
    // str == "abcd1234"

str = xmldoc.getNodeText("/three");
    // str == "1234abcd"

str = xmldoc.getNodeText("/test/one/*");
    // str == "abcd1234"

str = xmldoc.getNodeInt("/number");
    // str == 1234
```
The following examples locate the node by XPath and uses the API on node and element to get attributes and value.

```javascript
var node = xmldoc.getNode("/test/one/two");
// node.getNodeName() == "two"
// node.getNodeType() == "1" // 1 == ELEMENT_NODE
// node.getLastChild().getNodeType() == "3" // 3 == TEXT_NODE
// node.getLastChild().getNodeValue() == "abcd1234"
```

Or you can use the following convenience functions to get the node name and type

```javascript
str = xmldoc.getNodeName("//three");
// str == "three"

str = xmldoc.getNodeType("//three");
// str == "1"
```

You can also get a list of nodes that you can iterate or access directly by position

```javascript
var nodelist = xmldoc.getNodes("//one/*"); // two, three, and two
// nodelist.getLength() == "3"
// nodelist.item(0).getNodeName() == "two"
// nodelist.item(1).getNodeName() == "three"
```

The following is an example of parsing an XML string that is qualified with namespaces.

```javascript
    "<bk:title>Cheaper by the Dozen</bk:title>" +
    "<isbn:number>1568491379</isbn:number>" +
    "</bk:book>";

var xmldoc = new XMLDocument(xmlString, true);
var str = xmldoc.getNodeText("//bk:title"); // returns the first occurrence of the node
gs.log(str);

str = xmldoc.getNodeText("/bk:book/*");
gs.log(str);

str = xmldoc.getNodeInt("//isbn:number");
gs.log(str);
```

### Getting attribute values

An attribute is just an extension of a node and so it has all the same APIs.
The following example shows how to query for a node to get its attribute by position

```javascript
node = xmldoc.getNode("//two");
// node.getAttributes().item(0).getNodeValue() == "xxx"

str = xmldoc.getAttribute("//two", "att");
// str == "xxx"
```

XPath also has a query syntax for locating the attribute node directly, for example

```javascript
str = xmldoc.getNodeText("//*[@att="yyy"]");
// str == "1234abcd"

str = xmldoc.getNode("//@boo").getNodeValue();
// str == "yah"
```

## Creating new elements

An XML element can be created at any level of the XML document once it has been created. Use the `setCurrent` function to position where the new element will be created as a child element, and use the `createElement` function to create the element.

```javascript
var xmlString = "<test>" +
    "  <one>" +
    "    <two att="xxx">abcd1234</two>" +
    "    <three boo="yah" att="yyy">1234abcd</three>" +
    "    <two>another</two>" +
    "  </one>" +
    "  <number>1234</number>" +
"</test>";

var xmldoc = new XMLDocument(xmlString);
xmldoc.createElement("new", "test"); // creates the new element at the document element level if setCurrent is never called
xmldoc.createElement("new2"); // calling without a value will create a new element by itself

var el = xmldoc.createElement("new3");
xmldoc.setCurrent(el); // this is now the parent of any new elements created subsequently using createElement()
xmldoc.createElement("newChild", "test");
```

The resulting XML document looks like this
XMLHelper

The XML helper script include makes it easy to parse XML in scripts.

The script include converts your XML document into a JavaScript object.

The following changes were made to the XML helper script include:

• The `toObject()` method returns an object whose properties are all JavaScript objects. This method works properly whether the supplied parameter is an XML document or an XML string.

• The methods `toXMLDoc()` and `toXMLStr()` have been made available. These methods are the inverse of the existing `toObject()` method.

• The `toObject()` method has been extended to take an optional parameter of the XML input to convert as an alternative to the (still present) mechanism of specifying the XML input in the constructor.

⚠️ **Note:** You must escape ampersand characters (&amp) in your XML or the conversion silently fails.

Example

The following example takes an example XML document and then converts it into a JavaScript object. It then takes the outputted JavaScript object and uses a recursive function to output all members of the object. The recursive function is useful and reusable if you have any questions about how a particular XML document will be structured after being converted to a JavaScript object.

Script

```javascript
var xmlString = "<company><employee><id>10</id>
  <firstname>Tom</firstname><lastname>Cruise</lastname></employee></company>"
```
<employee>
  <id>20</id>
  <firstname>Paul</firstname>
  <lastname>Enderson</lastname>
  <test>test6</test>
</employee>

<employee>
  <id>30</id>
  <firstname>Paul</firstname>
  <lastname>Bush</lastname>
</employee>

var helper = new XMLHelper(xmlString);
var obj = helper.toObject();

logObj(obj,"");
function logObj(obj, sep){
  for(x in obj){
    if(typeof obj[x]!="function"{
      gs.log(sep + x +": ": + obj[x]);
      logObj(obj[x], sep +"*";});
  }
}

Output

*** Script: *employee:: [object Object],[object Object],[object Object]
*** Script: **2:: [object Object]
*** Script: ***id:: 30
*** Script: ***test:: test2,test4
*** Script: ****0:: test2
*** Script: ****1:: test4
*** Script: ***firstname:: Paul
*** Script: ***lastname:: Bush
*** Script: **0:: [object Object]
*** Script: ***id:: 10
*** Script: ***test:: test1,test3
*** Script: ****0:: test1
*** Script: ****1:: test3
*** Script: ***firstname:: Tom
*** Script: ***lastname:: Cruise
*** Script: **1:: [object Object]
*** Script: ***id:: 20
*** Script: ***test:: test6,test5
*** Script: ****0:: test6
*** Script: ****1:: test5
*** Script: ***firstname:: Paul
*** Script: ***lastname:: Enderson
JavaScript API Context-sensitive help

The syntax editor can display context-sensitive API information. JavaScript API Context-sensitive help includes the ability to:

- List script elements that are valid at the cursor's location. The system displays suggestions in a pop-up window.
- Add a selected script element at the cursor's location. If the cursor is within or adjacent to a partial entry, the system completes the entry with the selected script element.
- View API documentation for a selected suggestion.
- View the expected parameters and format of the current script element.

If the cursor is adjacent to a text string, the system searches for script elements that start with this text string. For example, while the cursor is within or adjacent to the string `GlideR`, the system displays script elements such as:

- GlideRecord
- GlideRecordSecure

Context-sensitive suggestions are based on script type. For example, when working on a business rule, only suggestions from the server API and for objects such as `current` and `previous` display. When working on a client script, the system only displays suggestions from the client API.

Client-side scripting

Run JavaScript on the client (web browser) when client-based events occur, such as when a form loads, after form submission, or when a field changes value.

The client-side Glide API provides classes and methods that you can use in client scripts.

Before you begin

Understand the limitations of your scripting environment. For example, client scripts run on forms in the Service Portal or Mobile environments can only include certain APIs. For more information, see Mobile client GlideForm (g form) scripting and migration.

Client-side scripting design and processing

Well-designed client scripts can reduce the amount of time it takes users to complete a form.
Proper client-side processing depends on the form loading first. Making record updates prior to form load can produce unexpected results that bypass client-side processing.

If you create client scripts to control field values on a form, you must use another method to control these field values in a list. You can:

- Disable list editing for the table.
- Create appropriate business rules or access controls for list editing.
- Create data policies.
- Create a separate onCellEdit client script.

**Restrict list editing**

If you create UI policies or client scripts for fields on a form, you must use another method to ensure that data in those fields is similarly controlled in a list.

With the exception of onCellEdit client scripts, UI policies and client scripts apply to forms only. Use the following methods to restrict list editing when using client scripts:

- Disable list editing for the table.
- Create appropriate business rules or access controls for list editing.
- Create data policies.
- Create a separate onCellEdit client script.

**Minimize server lookups**

Use client data as much as possible to eliminate the need for time-consuming server lookups.

Client scripting uses either data available on the client or data retrieved from the server. The top ways to get information from the server are g_scratchpad and asynchronous GlideAjax lookup.

The primary difference between these methods is that g_scratchpad is sent once when a form is loaded (information is pushed from the server to the client), whereas GlideAjax is dynamically triggered when the client requests information from the server.

**Note:** GlideRecord and g_form.getReference() are also available for retrieving server information. However, these methods are no longer recommended due to their performance impact. Both methods retrieve all fields in the requested GlideRecord when most cases only require one field.
Example: Retrieve server data using g_scratchpad

The g_scratchpad object passes information from the server to the client, such as when the client requires information not available on the form.

For example, if you have a client script that needs to access the field u_retrieve, and the field is not on the form, the data is not available to the client script. A typical solution to this situation is to place the field on the form and then always hide it with a client script or UI policy. While this solution may be faster to configure, it is slower to execute.

If you know what information the client needs from the server before the form is loaded, a display business rule can create g_scratchpad properties to hold this information. The g_scratchpad is sent to the client when the form is requested, making it available to all client-side scripting methods. This is a very efficient means of sending information from the server to the client. However, you can only load data this way when the form is loaded. The business rule cannot be triggered dynamically. In those cases, use an asynchronous GlideAjax call.

For example, assume you open an incident and need to pass this information to the client:

- The value of the system property css.base.color
- Whether or not the current record has attachments
- The name of the caller's manager

A display business rule sends this information to the client using the following script:

```javascript
const g_scratchpad = {);

// Save the information
g_scratchpad.css = gs.getProperty('css.base.color');
g_scratchpad.hasAttachments = current.hasAttachments();
g_scratchpad.managerName = current.caller_id.manager.getDisplayValue();
```

To access scratchpad data using a client script:

```javascript
// Check if the form has attachments
if (g_scratchpad.hasAttachments)
  // do something interesting here
else
  alert('You need to attach a form signed by ' + g_scratchpad.managerName);
```

Example: Retrieve server data using asynchronous GlideAjax

Asynchronous GlideAjax allows you to dynamically request information from the server.

This script compares the support group of the CI and the assignment group of the incident by name:
// Alert if the assignment groups name matches the support group
function onChange(control, oldValue, newValue, isLoading) {

    if (isLoading)
        return;

    var ga = new GlideAjax('ciCheck');
    ga.addParam('sysparm_name', 'getCiSupportGroup');
    ga.addParam('sysparm_ci', g_form.getValue('cmdb_ci'));
    ga.addParam('sysparm_ag', g_form.getValue('assignment_group'));
    ga.getXML(doAlert); // Always try to use asynchronous (getXML) calls rather than synchronous (getXMLWait)
}

// Callback function to process the response returned from the server
function doAlert(response) {

    var answer = response.responseXML.documentElement.getAttribute("answer");

    alert(answer);
}

This script relies on the accompanying script include:

var ciCheck = Class.create();

ciCheck.prototype = Object.extendsObject(AbstractAjaxProcessor, {

    getCiSupportGroup: function() {

        var retVal = ''; // Return value
        var ciID   = this.getParameter('sysparm_ci');
        var agID   = this.getParameter('sysparm_ag');
        var ciRec  = new GlideRecord('cmdb_ci');

        // If we can read the record, check if the sys_ids match
        if (ciRec.get(ciID)) {
            if (ciRec.getValue('support_group') == agID)
                retVal = 'CI support group and assignment group match';
            else
                retVal = 'CI support group and assignment group do not match';
        }

        // Can't read the CI, then they don't match
Use the setValue() displayValue parameter for reference fields

When using setValue() on a reference field, include the displayValue parameter to avoid additional server calls.

When using setValue() on a reference field, be sure to include the reference field display value as the 3rd parameter. If you set the value without the displayValue, the instance does a synchronous call to retrieve the display value for the record you specified. This extra round trip to the server can impact performance.

This example demonstrates the incorrect way to call setValue:

```javascript
var id = '5137153cc611227c000bbd1bd8cd2005';

g_form.setValue('assigned_to', id); // Client needs to go back to the server to
// fetch the name that goes with this ID
```

Instead, include the display value as an optional parameter in setValue():

```javascript
var id = '5137153cc611227c000bbd1bd8cd2005';
var name = 'Fred Luddy';

g_form.setValue('assigned_to', id, name); // No server call required
```

Use UI policy instead of a client script

When possible, consider using a UI policy instead of a client script.

UI policies provide these benefits over client scripts:

- UI policies have an Order field to allow full control over the order in which client-side operations take place.
- UI policies do not require scripting to make a field mandatory, read-only, or visible.

⚠️ Note: UI policies apply after client scripts.
Validate input using client scripts
An excellent use for client scripts is validating input from the user. This validation improves the user experience because the user finds out if there are data issues before submitting the information.

An example of validation is to verify that the **Impact** field value is valid with the **Priority** field value. In this example, **Low** impact is not allowed with **High** priority.

```javascript
if (g_form.getValue('impact') == '3' && g_form.getValue('priority') == '1')
    g_form.showFieldMsg('impact', getMessage('Low impact now allowed with High priority'), 'error');
```

Set client script order
Control the order of execution for your client scripts using the Order field. To avoid having two or more client scripts run concurrently and then conflict, you can add an order for the scripts to run in.

Before you begin
Role required: admin

About this task
Adding an order to the client script creates a processing sequence, ordered from lowest to highest number. If two scripts conflict, the client script with the lower number executes first.

Procedure
1. Navigate to **System Definition > Client Script** and open an existing client script or click **New**.
2. Configure the form to include the **Order** field.
3. Add a number to the order field based on what order you want it to run in relation to other client scripts. Choose a lower number for the script you want to execute first.

Avoid DOM manipulation
Avoid Document Object Model (DOM) manipulation if possible. It can cause a maintainability issue when browsers are updated.

Instead, use the GlideForm API or consider a different approach for the solution. In general, when using DOM manipulation methods, you have to reference an element in the DOM by ID or using a CSS selector. When referencing out-of-box DOM elements, there is a risk that the element ID or placement within the DOM
could change, causing the code to stop working and/or generate errors. Use forethought, caution, and have a full understanding of the risk you are incurring. Review these objects and reduce the use of DOM manipulation methods as much as possible.

Avoid global client scripts

A global client script is any client script where the selected Table is Global. Global client scripts have no table restrictions, therefore they will load on every page in the system introducing browser load delay in the process.

There is no benefit to loading this kind of scripts on every page.

As an alternative, and for a more modular and scalable approach, consider moving client scripts to a base table (such as Task[task] or Configuration Item[cmdb_ci]) that can be derived for all the child/extension tables. This eliminates the system loading the scripts on every form in the UI - such as home pages or Service Catalog where they are rarely (if ever) needed.

Enclose code in functions

Enclose the code in a client script inside a function.

Client scripts without a function cause issues with variable scope. When code is not enclosed in a function, variables and other objects are available and shared to all other client-side scripts. If you are using the same variable names, it is possible that they could collide. This can lead to unexpected consequences that are difficult to troubleshoot.

Consider this example:

```javascript
var state = "6";

function onSubmit() {
    if(g_form.getValue('incident_state') == state) {
        alert("This incident is Resolved");
    }
}
```

Because the `state` variable is not enclosed in a function, all client-side scripts have access to it. Other scripts may also use the common variable name `state`. The duplicate names can conflict and lead to unexpected results. These issues are difficult to isolate and resolve. To avoid this issue, ensure that all code is wrapped in a function:
function onSubmit() {

    var state = "6";

    if(g_form.getValue('incident_state') == state) {
        alert("This incident is Resolved");
    }
}

This solution is much safer because the scope of the variable state is limited to the onSubmit() function. Therefore, the state variable does not conflict with state variables in other client-side scripts.

**Run only necessary scripts**

To avoid running time-consuming scripts unnecessarily, make sure that client scripts perform only necessary tasks.

The following examples demonstrate improvements to the initial code sample. Each example demonstrates a particular enhancement to the script to improve performance and avoid unnecessary calls.

Remember that client scripts have no **Condition** field. This means that onLoad() and onChange() scripts run in their entirety every time the appropriate form is loaded. This example is an inefficient onChange() client script set to run when the Configuration item field changes.

```javascript
//Set Assignment Group to CI's support group if assignment group is empty
function onChange(control, oldValue, newValue, isLoading) {

    var ciSupportGroup = g_form.getReference('cmdb_ci').support_group;

    if (ciSupportGroup != '' && g_form.getValue('assignment_group) != '')
        g_form.setValue('assignment_group', ciRec.support_group.sys_id);
}
```

This example improves upon the first by replacing the getReference() or GlideRecord lookup with an asynchronous GlideAjax call.

```javascript
//Set Assignment Group to support group if assignment group is empty
function onChange(control, oldValue, newValue, isLoading) {

    var ga = new GlideAjax('ciCheck');

    ga.addParam('sysparm_name', 'getSupportGroup');
    ga.addParam('sysparm_ci', g_form.getValue('cmdb_ci'));
```
The `isLoading` flag is the simplest way to prevent unnecessary code from taking up browser time in `onChange` scripts. The `isLoading` flag should be used at the beginning of any script that is not required to run when the form is loading. There is no need to run this script on a form load because the logic would have already run when the field was last changed. Adding the `isLoading` check to the script prevents it from doing a `cmdb_ci` lookup on every form load.

The `isTemplate` flag indicates that a template is loading.

```javascript
// Set Assignment Group to CI's support group if assignment group is empty
function onChange(control, oldValue, newValue, isLoading, isTemplate) {
  if (isLoading)
    return;

  var ga = new GlideAjax('ciCheck');

  ga.addParam('sysparm_name', 'getSupportGroup');
  ga.addParam('sysparm_ci', g_form.getValue('cmdb_ci'));
  ga.getXML(setAssignmentGroup);
}

function setAssignmentGroup(response) {
  var answer = response.responseXML.documentElement.getAttribute("answer");

  g_form.setValue('assignment_group', answer);
}
```

If the `onChange` script should run during loading, use the following convention:

```javascript
function onChange(control, oldValue, newValue, isLoading, isTemplate) {
  if (isLoading) {} // run during loading

  // rest of script here
}
The `newValue` check tells this script to continue only if there is a valid value in the relevant field. This prevents the script from running when the field value is removed or blanked out. This also ensures that there will always be a valid value available when the rest of the script runs.

```javascript
//Set Assignment Group to CI's support group if assignment group is empty
function onChange(control, oldValue, newValue, isLoading, isTemplate) {
    if (isLoading)
        return;

    if (newValue) {
        var ga = new GlideAjax('ciCheck');
        ga.addParam('sysparm_name', 'getSupportGroup');
        ga.addParam('sysparm_ci', g_form.getValue('cmdb_ci'));
        ga.getXML(setAssignmentGroup);
    }
}

function setAssignmentGroup(response) {
    var answer = response.responseXML.documentElement.getAttribute("answer");
    g_form.setValue('assignment_group', answer);
}
```

To have the script react to a value that changes after the form loads, use the `newValue != oldValue` check.

**Note:** This example does not catch users changing a value and then changing it back to its original value.
In this example, the GlideAjax call is buried one level deeper by rearranging the script to check as many things available to the client as possible before running the server calls. The script checks the assignment before executing the GlideAjax call. This prevents the server lookup when the assignment_group field is already set.

```javascript
// Set Assignment Group to CI's support group if assignment group is empty
function onChange(control, oldValue, newValue, isLoading, isTemplate) {
  if (isLoading)
    return;

  if (newValue) {
    if (newValue != oldValue) {
      if (g_form.getValue('assignment_group') == '') {
        var ga = new GlideAjax('ciCheck');
        ga.addParam('sysparm_name', 'getSupportGroup');
        ga.addParam('sysparm_ci', g_form.getValue('cmdb_ci'));
        ga.getXML(setAssignmentGroup);
      }
    }
  }
}

function setAssignmentGroup(response) {
  var answer = response.responseXML.documentElement.getAttribute("answer");
  g_form.setValue('assignment_group', answer);
}
```
Client scripts

Client scripts allow the system to run JavaScript on the client (web browser) when client-based events occur, such as when a form loads, after form submission, or when a field changes value.

Use client scripts to configure forms, form fields, and field values while the user is using the form. Client scripts can:

- make fields hidden or visible
- make fields read only or writable
- make fields optional or mandatory based on the user's role
- set the value in one field based on the value in other fields
- modify the options in a choice list based on a user's role
- display messages based on a value in a field

Introduction to client scripts, script types, APIs, and good practices

Where client scripts run

With the exception of `onCellEdit()` client scripts, client scripts only apply to forms and search pages. If you create a client script to control field values on a form, you must use one of these other methods to control field values when on a list.

- Create an access control to restrict who can edit field values.
- Create a business rule to validate content.
- Create a data policy to validate content.
- Create an `onCellEdit()` client script to validate content.
- Disable list editing for the table.

⚠️ Note: Client scripts are not supported on ServiceNow mobile applications.

Client script form

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the client script.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>

<tr>
<td>Table</td>
<td>Table to which the client script applies.</td>
</tr>
<tr>
<td>UI Type</td>
<td>Target user interface to which the client script applies.</td>
</tr>
<tr>
<td>Type</td>
<td><strong>onLoad()</strong> — runs when the system first renders the form and before users can enter data. Typically, <strong>onLoad()</strong> client scripts perform client-side-manipulation of the current form or set default record values.</td>
</tr>
<tr>
<td></td>
<td><strong>onSubmit()</strong> — runs when a form is submitted. Typically, <strong>onSubmit()</strong> scripts validate things on the form and ensure that the submission makes sense. An <strong>onSubmit()</strong> client script can cancel form submission by returning a value of false.</td>
</tr>
<tr>
<td></td>
<td><strong>onChange()</strong> — runs when a particular field value changes on the form. The <strong>onChange()</strong> client script must specify these parameters.</td>
</tr>
<tr>
<td></td>
<td>• <strong>control</strong>: the DHTML widget whose value changed.</td>
</tr>
<tr>
<td></td>
<td>• <strong>oldValue</strong>: the value the widget had when the record was loaded.</td>
</tr>
<tr>
<td></td>
<td>• <strong>newValue</strong>: the value the widget has after the change.</td>
</tr>
<tr>
<td></td>
<td>• <strong>isLoading</strong>: identifies whether the change occurs as part of a form load.</td>
</tr>
<tr>
<td></td>
<td>• <strong>isTemplate</strong>: identifies whether the change occurs as part of a template load.</td>
</tr>
<tr>
<td></td>
<td><strong>onCellEdit()</strong> — runs when the list editor changes a cell value. The <strong>onCellEdit()</strong> client script must specify these parameters.</td>
</tr>
<tr>
<td></td>
<td>• <strong>sysIDs</strong>: an array of the sys_ids for all items being edited.</td>
</tr>
<tr>
<td></td>
<td>• <strong>table</strong>: the table of the items being edited.</td>
</tr>
<tr>
<td></td>
<td>• <strong>oldValues</strong>: the old values of the cells being edited.</td>
</tr>
<tr>
<td></td>
<td>• <strong>newValue</strong>: the new value for the cells being edited.</td>
</tr>
<tr>
<td></td>
<td>• <strong>callback</strong>: a callback that continues the execution of any other related cell edit scripts. If <strong>true</strong> is passed as a parameter, the other scripts are executed or the</td>
</tr>
</tbody>
</table>
change is committed if there are no more scripts. If false is passed as a parameter, any further scripts are not executed and the change is not committed.

Note: onCellEdit() client scripts do not apply to dashboard list widgets.

<table>

</tbody>
</table>

**UI scripts**

UI scripts provide a way to package client-side JavaScript into a reusable form, similar to how script includes store server-side JavaScript. Administrators can create UI scripts and run them from client scripts and other client-side script objects and from HTML code.

UI scripts are not supported for mobile.

**Global UI scripts**

You can create a UI script and designate it as global, which makes the script available on any form in the system. You cannot create a global UI script in a scoped application.
You can mark a UI script as Global to make it available on any form in the system. For example, you can create a UI script that has a function `helloWorld()`, and has the Global field checked:

```javascript
function helloWorld() {
    alert('Hi');
}
```

After you create this global UI script, you can call the `helloWorld()` function from any client script or UI policy you write.

**Create a UI script**

Create a UI script to define reusable client-side JavaScript code.

**Procedure**

To create UI scripts, navigate to **System UI > UI Scripts** and create or edit a record (see table for field descriptions).

**Run UI scripts**

Follow these guidelines when running UI scripts.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Script Name</td>
<td>Name of the UI script. Ensure the name is unique on your system.</td>
</tr>
<tr>
<td>API Name</td>
<td>The API name of the UI script, including the scope and script name (for example, x_custom_app.HelloWorld).</td>
</tr>
<tr>
<td>Application</td>
<td>Application that contains the UI script.</td>
</tr>
<tr>
<td>Active</td>
<td>Indicator of whether the UI script is active. Only active UI scripts can run.</td>
</tr>
<tr>
<td>Global</td>
<td>Indicator of whether the script loads on every page in the system.</td>
</tr>
</tbody>
</table>

**Note:** Use caution when creating global UI scripts because they can impact performance. You cannot create a global UI script in a scoped application.
Run a UI script from a form

To run a UI script on a form, create a formatter. In the associated UI macro, include a \texttt{g:requires} tag and specify the \texttt{name=} parameter as the name of the UI script followed by the .jsdbx extension. Add the formatter on the form view. This code ensures that the definitions and results of the UI script are immediately available in the browser.

```xml
<?xml version="1.0" encoding="utf-8" ?>
<j:jelly trim="false" xmlns:j="jelly:core" xmlns:g="glide" xmlns:j2="null" xmlns:g2="null">
  <g2:evaluate var="jvar_stamp">
    var now_GR = new GlideRecord('sys_ui_script');
    gr.orderByDesc('sys_updated_on');
    gr.query();
    gr.next();
    gr.getValue('sys_updated_on');
  </g2:evaluate>
  <g:requires name="<UI SCRIPT NAME>.jsdbx" params="cache=$[jvar_stamp]" />
</j:jelly>
```

Call a UI script in HTML

To run a UI script from HTML code, use the \texttt{<script>} tag and specify the \texttt{src=} argument as the API name of the UI script followed by the .jsdbx extension. For example, include the UI script named CoolClock with this code:

```html
<script language="javascript" src="CoolClock.jsdbx" />
```

Call a UI script from client-side code

Access UI scripts from within client-side code using the \texttt{g\_ui\_scripts} global object. For more information, see GlideUIScripts - Client.

\textbf{Note:} This class does not support UI scripts with the \texttt{Global} field set to true.

Catalog client scripts

Client-side scripts can add dynamic effects and validation to forms. Scripts can apply to service catalog items or variable sets, allowing administrators to use the same functionality that is available on other forms.

You can use client side scripts to:

- Get or set variable values.
- Hide or display variables.
• Make variables mandatory or not.
• Validate form submission.
• Add something to the cart.
• Order something immediately.

**Catalog client script considerations**
When you create catalog client scripts, be aware of the following considerations.

• Catalog client scripts run when a user orders an item from the service catalog. Catalog client scripts can also run when variables or variable sets for a catalog item are displayed when a user requests that item.
• For a variable to be accessible using a catalog client script, it must have a variable name. Variables without names do not appear in the list of available variables.
• When using standard client scripts on a Requested Item or Catalog Task form, make a note of fields with the same name as variables. If a table field and a variable of the same name are both present on a form, the table field is matched when it is accessed using a script. If this happens, specifically address the variable by naming it `variables.variable name`. For example:
  ```javascript
g_form.setValue('variables.replacement', 'false');
  ```
• If you are using record producers to pass variables from the service catalog to other types of records, these variables are made visible in those records with a variable editor, such as the Change Variable Editor UI formatter on Change request forms. You can manipulate these variables using standard client script methods, such as `setDisplay`, `setMandatory`, `setValue`, and `getValue`.
• Catalog client scripts can be used for catalog items included in a wizard.
• You can use the `g_form.refreshSlushbucket(fieldName)` API to update a list collector variable.

**Catalog client script differences**
Catalog client scripts are very similar to standard client scripts, with a few important differences.
Instead of selecting a table such as Incident for the script, select a catalog item or variable set. As your system may have a large number of catalog items, you should select a catalog item or variable set using a reference field instead of the choice list that the standard Client Script form uses.

When using an `onChange()` catalog client script, it is linked to a particular variable instead of a field. The system automatically populates the variable name selection list with any named variables from the catalog item or variable set selected.

Create a catalog client script

Follow this procedure to create a catalog client script.

**Procedure**

1. Navigate to Service Catalog > Catalog Administration > Catalog Client Scripts.
   A list of current custom catalog client scripts appears.
2. Click New.
3. Fill in the fields, as appropriate (see table).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter a unique name for the catalog client script.</td>
</tr>
<tr>
<td>Applies to</td>
<td>Select the item type this client script applies to:</td>
</tr>
<tr>
<td></td>
<td>• A Catalog Item: enables the Catalog item field.</td>
</tr>
<tr>
<td></td>
<td>• A Variable Set: enables the Variable set field.</td>
</tr>
<tr>
<td>Active</td>
<td>Select the check box to enable the client script. Clear the check box to</td>
</tr>
<tr>
<td></td>
<td>disable the script.</td>
</tr>
<tr>
<td>UI Type</td>
<td>Whether to apply this to desktop, mobile, or both.</td>
</tr>
<tr>
<td>Script</td>
<td>Enter the client script that should run on the service catalog item.</td>
</tr>
<tr>
<td>Type</td>
<td>Select when the script should run, such as <code>onLoad</code> or <code>onSubmit</code>.</td>
</tr>
<tr>
<td>Catalog item or</td>
<td>Select a catalog item or variable set from the list. The field name and</td>
</tr>
<tr>
<td>Variable set</td>
<td>options available depend on the selection in the Applies to field.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Applies on a Catalog Item view</td>
<td>Select the check box to apply the catalog client script to catalog items displayed within the order screen on the service catalog. Available in the requester view.</td>
</tr>
<tr>
<td>Applies on Requested Items</td>
<td>Select the check box to apply the catalog client script on a Requested Item form, after the item is requested. Available in the fulfiller view. See VEditor.</td>
</tr>
<tr>
<td>Applies on Catalog Tasks</td>
<td>Select the check box to apply the catalog client script when a Catalog Task form for the item is being displayed. Available in the fulfiller view. See VEditor.</td>
</tr>
<tr>
<td>Applies on the Target Record</td>
<td>Select the check box to support the catalog UI policy on a record created for task-extended tables via record producers. See Default variable editor.</td>
</tr>
</tbody>
</table>

4. Click Submit.

**Catalog client script examples**

Examples of client scripts to perform common actions.

**Example: Get the value of a variable**

Use the following syntax to obtain the value of a catalog variable. Note that the variable must have a name. Replace `variable_name` with the name of the variable.

```javascript
g_form.getValue('variable_name');
```

**Example: Restrict the number of characters a user can type in a variable**

This is an example of a script that runs when the variable is displayed, rather than when the item is ordered.

```javascript
function onLoad(){
   var sd = g_form.getControl('short_description');
   sd.maxLength=80;
}
```

**Mobile client GlideForm (g form) scripting and migration**

Client scripting for mobile is identical to scripting for the web, with some exceptions. All new scripts must conform to certain guidelines. The following
items are affected on the mobile platform: client scripts, UI policies, navigator modules, and UI actions.

**Client scripts**
For new or existing scripts to be valid for mobile, they must conform to the following requirements:

- Use the new mobile methods in place of `g_form.getControl()`.
- Do not use deprecated methods.
- Do not reference unsupported browser objects.
- Do not make synchronous JavaScript, GlideAjax, and GlideRecord calls.
- Do not call methods that are not available for mobile.
- Enable scripts to run on the mobile UI.

---

**Requirements**

| Use the new mobile methods | Several new methods are available for modifying form fields instead of directly manipulating the HTML. These methods replace previous usages of `g_form.getControl()`, which is deprecated for the mobile platform. In your existing scripts, ensure that the new methods are used in place of methods that are not valid on the mobile platform. For information on these new methods, refer to Mobile GlideForm() API. |
| Do not use deprecated methods | The following methods have been deprecated for the mobile platform because direct access to HTML elements is not allowed: |
| Do not reference unsupported browser objects | The following browser objects are not supported in mobile scripts: |

- `g_form.getControl()`
- `g_form.getFormElement()`
- `g_form.getElement()`

To ensure that existing scripts are compatible, remove all calls to deprecated methods from your code. For new scripts, do not use deprecated methods if you want the script to be valid for mobile.

For `g_form.getControl()`, some of the functionality previously included with this method has been extracted to individual methods. Instead of `g_form.getControl()` use the new methods described on the developer site.

- Window
- jQuery or Prototype ($, $j, or $$)
- Document
Requirements (continued)

<table>
<thead>
<tr>
<th>Requirements</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Make sure that new scripts do not use these objects, and remove any usage of these objects from your existing scripts. Use GlideForm (g_form) instead, which provides methods such as setLabel(), addDecoration(), and hasField() for accomplishing the same tasks.</td>
<td></td>
</tr>
<tr>
<td>Do not make synchronous JavaScript calls</td>
<td>The mobile platform does not allow synchronous JavaScript calls. The <code>g_form.getReference()</code> method must now have the callback parameter defined. For example: <code>g_form.getReference(fieldName, callback)</code></td>
</tr>
<tr>
<td></td>
<td>Be sure that all <code>g_form.getReference()</code> calls include the callback parameter. For example, the following script does not include a callback and is incompatible with the mobile platform:</td>
</tr>
</tbody>
</table>
|                                                   | ```javascript
var userName = g_form.getReference('assigned_to').user_name;
g_form.setValue('u_assigned_user_name', userName);
```
|                                                   | The following script has been updated to include the callback and is compatible with the mobile platform:                                                                                                                     |
|                                                   | ```javascript
function(now_GR) {
    g_form.setValue('u_assigned_user_name', gr.user_name);
};
g_form.getReference('assigned_to', function(now_GR) {
    g_form.setValue('u_assigned_user_name', now_GR.user_name);
});
```
| Do not make synchronous GlideAjax calls           | The mobile platform does not allow synchronous GlideAjax calls. Any use of `getXMLWait()` in a GlideAjax call will not work on the mobile platform. Be sure that all GlideAjax calls are asynchronous. For more on synchronous versus asynchronous GlideAjax calls and `getXMLWait()`, see AJAX. For information on the available GlideAjax methods, refer to the GlideAjax API. |
| Do not make synchronous GlideRecord calls         | The mobile platform does not allow synchronous GlideRecord calls. Make sure that any existing GlideRecord calls include a callback. For example, the following script does not include a callback and is incompatible with the mobile platform: |
|                                                   | ```javascript
var now_GR = new GlideRecord('incident');
gr.addQuery('number', g_form.getValue('related_incident'));
gr.query();
gr.next();
g_form.setValue('u_related_incident_description', gr.short_description);
```
|                                                   | The following script has been updated to include the callback, and is compatible with the mobile platform:                                                                                                                     |
|                                                   | ```javascript
var now_GR = new GlideRecord('incident');
gr.addQuery('number', g_form.getValue('related_incident'));
```
Do not use methods unavailable on the mobile platform

<table>
<thead>
<tr>
<th>Do not use methods unavailable on the mobile platform</th>
<th>Due to the limitations and reduced functionality that is imposed by the mobile platform, the following methods are not deprecated but are not available on the mobile platform. If these run on the mobile platform, no action occurs:</th>

</tr>
</tbody>
</table>

Enable scripts for mobile

Scripts must be enabled for the mobile platform. See Enable client scripts for the mobile browser for the ServiceNow Classic mobile app.

Note: Focusing an element on a mobile form is not supported.

UI policies

Use the Run scripts in UI type field to determine whether scripts run on the mobile platform, the desktop, or both. Update existing policies so that they apply to either the mobile platform or both. For new scripts, also ensure that the mobile option or both is selected. For more on UI policies for mobile, see Enable UI policies for the mobile browser.

Navigator modules

For existing code, modules must be transferred to either the sys_ui_application or sys_ui_module tables to be available on the mobile platform. When developing new code, be sure that all modules are created in the sys_ui_application or...
sys_ui_module tables. For more information, see Enable an application menu for the ServiceNow Classic mobile app.

**UI actions**

UI actions must be transferred to the sys_ui_ng_action table to appear on the mobile platform. UI action scripts that do not use deprecated methods do not require changes to the script itself. For new UI actions, be sure that they are created in the sys_ui_ng_action table. For more information, see Mobile UI actions for the ServiceNow Classic mobile app.

**AJAX**

AJAX (asynchronous JavaScript and XML) is a group of interrelated, client-side development techniques used to create asynchronous Web applications. AJAX enables web applications to send and retrieve information to and from a server in the background, without impacting the user experience with the displayed web page.

**GlideAjax**

The GlideAjax class allows the execution of server-side code from the client. GlideAjax calls pass parameters to the script includes, and, using naming conventions, allows the use of these parameters.

!? Note: This functionality requires a knowledge of JavaScript.

Using GlideAjax:

- Initialize GlideAjax with the name of the script include that you want to use.
- When creating the script include, you must set the name field to be exactly the same as the class name.
- When creating the script include, you must select the Client callable check box.
- Specify the parameter sysparm_name. GlideAjax uses sysparm_name to find which function to use.
- Any extra parameters may be passed in, all of which must begin with sysparm_. Avoid using predefined parameter names:
  - sysparm_name
  - sysparm_function
  - sysparm_value
  - sysparm_type
- Code is then executed with the getXML() or getXMLWait() functions.
For additional information on GlideAjax, refer to GlideAjax in the development portal.

**Examples of asynchronous GlideAjax**

There are two parts to the asynchronous GlideAjax script: client-side and server-side code.

**Hello World: Returning a value from the server**

**Example: Client side**

This code runs on the client (the web browser). Create a client script as normal. This sends the parameters to server, which then does the processing. So that the client does not wait for the result, a callback function is used to return the result, passed to the `getXML()` function. (In this case it is called `HelloWorldParse`.)

The `getXMLWait()` function does not need a separate callback function, but this will block the client. If the client-server communication takes a long time (for example on slow networks), the application will seem unresponsive and slow. An example of `getXMLWait()` is in the following section.

```javascript
var ga = new GlideAjax('HelloWorld');
ga.addParam('sysparm_name', 'helloWorld');
ga.addParam('sysparm_user_name', "Bob");
ga.getXML(HelloWorldParse);

function HelloWorldParse(response) {
    var answer = response.responseXML.documentElement.getAttribute("answer");
    alert(answer);
}
```

**Example: Server side**

The server-side code for the above function. Do not create a business rule, but instead navigate to **System Definition > Script Include** and create a new script. Paste in the code below.

ℹ️ **Note:** You must set the name of the script include to `HelloWorld`.

- The `sys_script_include` code must extend the `AbstractAjaxProcessor` class and be client-callable.
- Function names starting with "_" are considered private and are not callable from the client.
- Avoid overriding methods of `AbstractAjaxProcessor`, including `initialize`. While it is possible to invoke methods of your superclass object which you have overridden, it is complicated and best avoided altogether.
var HelloWorld = Class.create();
HelloWorld.prototype = Object.extendsObject(AbstractAjaxProcessor, {
    helloWorld:function() { return "Hello " + this.getParameter('sysparm_user_name') + "!"; },
    _privateFunction: function() { // this function is not client callable
    }
});

This results in an alert box that says 'Hello Bob!' when you visit the form.

**Returning multiple values**

Since the response is an XML document we are not limited to returning a single answer value. Here is a more complex example returning multiple XML nodes and attributes.

**Example: AJAX processor script include**

```javascript
/*
 * MyFavoritesAjax script include Description - sample AJAX processor returning multiple value pairs
 */
var MyFavoritesAjax = Class.create();
MyFavoritesAjax.prototype = Object.extendsObject(AbstractAjaxProcessor, {

    /*
     * method available to client scripts call using:
     * var gajax = new GlideAjax("MyFavoritesAjax");
     * gajax.addParam("sysparm_name","getFavorites");
     */
    getFavorites: function() { // build new response xml element for result
        var result = this.newItem("result");
        result.setAttribute("message","returning all favorites");

        //add some favorite nodes with name and value attributes
        this._addFavorite("color","blue");
        this._addFavorite("beer","lager");
        this._addFavorite("pet","dog");
    },
    // all items are returned to the client through the inherited methods of AbstractAjaxProcessor
    _addFavorite: function(name, value) {
        var favs = this.newItem("favorite");
        favs.setAttribute("name",name);
        favs.setAttribute("value",value);
    };
```

/* MyFavoritesAjax */

```javascript
Example: Client script

// new GlideAjax object referencing name of AJAX script include
var ga = new GlideAjax("MyFavoritesAjax");
// add name parameter to define which function we want to call
// method name in script include will be getFavorites
ga.addParam("sysparm_name","getFavorites");

// submit request to server, call ajaxResponse function with server response

function ajaxResponse(serverResponse) {
  // get result element and attributes
  var result = serverResponse.responseXML.getElementsByTagName("result");
  var message = result[0].getAttribute("message");

  // check for message attribute and alert user
  if(message) alert(message);

  // build output to display on client for testing
  var output = ";

  // get favorite elements
  var favorites = serverResponse.responseXML.getElementsByTagName("favorite");
  for(var i = 0; i < favorites.length; i++) {
    var name = favorites[i].getAttribute("name");
    var value = favorites[i].getAttribute("value");
    output += name + " = " + value + "\n";
  }

  alert(output); }
```

Example: XML response

```xml
<xml sysparm_max= "15" sysparm_name= "getFavorites" sysparm_processor= "MyFavoritesAjax">  
  <result message= "returning all favorites"></result>  
  <favorite name= "color" value= "blue"></favorite>  
  <favorite name= "beer" value= "lager"></favorite>
</xml>
```
Examples of synchronous GlideAjax

Use synchronous when your script cannot continue without the GlideAjax response. This stops the session until the response is received.

If your use case demands that no further processing can occur until the GlideAjax response has been received, you can use `getXMLWait()`. However, because this will slow down your code and lock the user session until the response is received, it is generally recommended that you use `getXML()` with a callback function.

⚠️ Note: Do not use `AJAXEvaluateSynchronously`.

⚠️ Note: The `getXMLWait()` method is not available in scoped applications.

This code results in a client-side alert that displays The Server Says Hello Bob!.

The client code.

```javascript
var ga = new GlideAjax('HelloWorld') ;
ga.addParam('sysparm_name','helloWorld');
ga.addParam('sysparm_user_name','Bob');
ga.getXMLWait();
alert(ga.getAnswer());
```

The server-side script include code.

```javascript
var HelloWorld = Class.create();
HelloWorld.prototype = Object.extendsObject(AbstractAjaxProcessor, { helloWorld: function() { return "The Server Says Hello " + this.getParameter('sysparm_user_name') + "!"; } });
```

AJAXClientHelper

Provides helper functions for Ajax clients to generate Choice Lists and retrieve displayed values from a choice list.

Where to use

Use this script include wherever your need to generate choice lists or retrieve a value from an Ajax client.
**Method summary**

Jelly tags

Use Jelly to turn XML into HTML.

Watch these introductory to learn about using Jelly in the Now Platform.

- Introducing Jelly Scripting - Part 1 (Video)
- Introducing Jelly Scripting - Part 2 (Video)
- Introducing Jelly Scripting - Part 3 (Video)

Jelly Tags

if

- **Description**: The `if` tag is just what it looks like, an if tag. This is like an if statement in any programming language, but keep in mind that there is no elseif tag and no else tag. If you want to create that kind of structure, try the choose/when/otherwise syntax.

- **Parameters**: `test` - The condition to evaluate in order to determine if the block will execute.

- **Example**:

```xml
<evaluate var="jvar_gr" object="true">
  var now_GR = new GlideRecord("incident");
  gr.addQuery("active", true);
  gr.query();
  gr;
</evaluate>

<if test="!jvar_gr.hasNext()">
  We did not find any active incidents.
</if>
<if test="jvar_gr.next()">
  We found ${jvar_gr.getRowCount()} active incidents.
</if>
```

© 2021 ServiceNow, Inc. All rights reserved.
while

- **Description**: The *while* tag does a while loop.
- **Parameters**:
  - **test** - The condition to evaluate in order to determine if the statement will loop through. This should be an expression enclosed in ${} or $[] that evaluates to true or false.
- **Example**:

  ```
  <g:evaluate var="jvar_gr" object="true">
    var now_GR = new GlideRecord("incident");
    gr.addQuery("active", true);
    gr.query();
    gr;
  </g:evaluate>

  <j:while test="${jvar_gr.next()}">
    <a href="incident.do?sys_id=${jvar_gr.getValue('sys_id')}">${jvar_gr.getValue('number')}</a>
  </j:while>
  ```

set

- **Description**: The *set* tag sets a variable.
- **Parameters**:
  - **var** - The variable to set. Often the system prefixes these variables with jvar_ for consistency.
  - **value** - The value to set var to. This is often an expression enclosed in ${} or $[].
  - **defaultValue** - If the value results to null or empty, this value is put into the var.
- **Example**:

  ```
  <j:set var="jvar_incident_number" value="${jvar_gr.getValue('number')}"/>
  ```

set_if
• **Description:** The `set_if` tag sets a variable based on a test. This tag is similar to the ternary operator in other programming languages (`var = <test> ? <if_true> : <if_false>`).

• **Parameters:**
  - `var` - The variable to set. Often the system prefixes these variables with `jvar_` for consistency.
  - `test` - The condition to evaluate in order to determine if the statement will evaluate the true value or the false value. This should be an expression enclosed in `${}` or `[]` that evaluates to true or false.
  - `true` - The value to set the variable to if `test` evaluates to `true`. This parameter is optional, so if the field is blank, and if `test` evaluates to `true`, the variable will be left blank.
  - `false` - The value to set the variable to if `test` evaluates to `false`. This parameter is optional, so if the field is blank, and if `test` evaluates to false, the variable will be left blank.

choose

• **Description:** The `choose` tag starts a choose block of code. This is similar to the if-elseif-else kind of syntax in most programming languages. With a `choose` tag, you can use `when` and `otherwise` tags to specify other blocks of code.

• **Parameters:** None.

• **Example:**

```<j:choose>
  <j:when test="${jvar_gr.getRowCount() AMP&lt; 1}">We found multiple records!</j:when>
  <j:when test="${jvar_gr.next()}">We found record ${jvar_gr.getValue('number')} </j:when>
  <j:otherwise>Sorry, we could not find the record you specified.</j:otherwise>
</j:choose>```

when

• **Description:** The `when` tag is used within a choose block to indicate a condition. This tag is similar to an if or an elseif in that it specifies a condition, executes the inner content, and then implies a break at the end to leave the if-elseif construct.
• **Parameters**: test - The condition to evaluate in order to determine if the statement will loop through. This should be an expression enclosed in ${[] or $[]} that evaluates to true or false.

• **Example**:

```xml
<j:choose>
  <j:when test="${jvar_gr.getRowCount() lt; 1}"">We found multiple records!</j:when>
  <j:when test="${jvar_gr.next()}"">We found record ${jvar_gr.getValue('number')}"</j:when>
  <j:otherwise>Sorry, we could not find the record you specified.</j:otherwise>
</j:choose>
```

`otherwise`

• **Description**: The `otherwise` tag is used within a `choose/when/otherwise` block, and is like the "else" or "default" case.

• **Parameters**: None.

• **Example**:

```xml
<j:choose>
  <j:when test="${jvar_gr.getRowCount() lt; 1}"">We found multiple records!</j:when>
  <j:when test="${jvar_gr.next()}"">We found record ${jvar_gr.getValue('number')}"</j:when>
  <j:otherwise>Sorry, we could not find the record you specified.</j:otherwise>
</j:choose>
```

**Glide Tags**

**evaluate**

• **Description**: The `evaluate` tag evaluates JavaScript code (server side), and makes variables visible to future code. Unlike other tags, the `evaluate` tag evaluates the content that is inside the tag as server side JavaScript.

The context is the same as that of script includes in the system. Other script includes, global business rules, GlideRecord, GlideSystem, and Jelly variables (prefixed with jelly. if the parameter jelly="true" is set) are available.

• **Parameters**: 

© 2021 ServiceNow, Inc. All rights reserved.
• **var** - The name of the variable that will be set to the result of the script.

• **object** - If set to **true**, the result of the expression will be treated as an object instead of a primitive variable (string or integer variable values).

• **jelly** - If set to **true**, allows Jelly context variables to be referenced in the script.

• **expression** - This is an expression to be executed for the value to put in **var**. The expression can be either of two places. First, it can be an attribute on the evaluate tag itself. Otherwise, the content between the beginning tag and ending tag is the expression. The last line of the expression is the actual value passed into **var**.

**Example:**

```xml
<g:evaluate var="jvar_gr" object="true">
    var now_GR = new GlideRecord("incident");
    gr.addQuery("active", "true");
    gr.query();
    gr; // this is the variable put into the variable jvar_gr
</g:evaluate>
```

```xml
<g:evaluate var="jvar_gr" object="true" expression=""
    var now_GR = new GlideRecord('incident');
    gr.addQuery('active', 'true');
    gr.query();
    gr; // this is the variable put into the variable jvar_gr" />
```

**messages**

• **Description**: The **messages** tag helps with translation. When `gs.getMessage()` is called anywhere on a page, there are two possible places where the translation is found. First, the page checks a local cache of translations. Second, the page makes an AJAX call to the server to find the translation. What `g:messages` does is allow pages to cache certain messages.

• **Parameters**: None.

• **Example**:

```xml
<g:messages>
    Yes
    No
</g:messages>
```
breakpoint

• **Description:** When the breakpoint tag is called, it prints a list of all the variables in Jelly at the current moment, with their respective values. If a variable is specified, it prints the requested variable and its value. The output is placed in the System Log.

• **Parameters:** `var` - (Optional) The variable to log the value for. If `var` is not specified, then all variables will be dumped into the log.

• **Example:**

  ```xml
  <g:breakpoint />
  <g:breakpoint var="sysparm_view"/>
  ```

no_escape

• **Description:** The system, by default, uses escaped output as a security measure. Output placed inside of no_escape tags is not escaped before output. Be careful when using these tags, because if user input is displayed here it can open a security vulnerability on the page.

• **Parameters:** None.

• **Example:**

  ```xml
  <g:no_escape>
  ${jvar_raw_html_data}
  </g:no_escape>
  ```

macro_invoke

• **Description:** The macro_invoke tag calls a UI macro that you have specified in the database. You may also call a UI macro by specifying it in the tag name. For example, if you had a UI macro named my_macro, you could call that macro with the tag `<g:my_macro/>`.

• **Parameters:**
- **macro** - The name of the UI macro to execute. If your tag name is `g:macro_invoke`, then the macro attribute specifies the name of the macro. If the tag name includes the name of the macro, then there is no need to include a macro attribute.

- **Other attributes** - For each attribute you specify, a variable with that name will be available in the context of the UI macro, prefixed with "jvar_".

**Example:**

```xml
<!-- Will invoke the contents of the UI macro named "sample_macro", which will have the variable jvar_message available within it-->
<g:macro_invoke macro="sample_macro" message="This is a sample macro variable." />

<!-- Will invoke the contents of the UI macro named "sample_macro", which will have the variable jvar_message available within it-->
<g:sample_macro message="This is a sample macro variable." />
```

---

### Jelly escaping types

You use different methods when escaping characters in JavaScript and HTML. JavaScript uses the backslash character, and HTML uses the ampersand character.

**Note:** This functionality requires a knowledge of JavaScript, HTML, and Apache Jelly (a Java and XML based scripting and processing engine for turning XML into executable code).

There are two different types of escaping that is required when generating output from Jelly:

- **JavaScript**
- **HTML**

The escaping for each of these consists of:

<table>
<thead>
<tr>
<th>Type</th>
<th>From</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>JavaScript</strong></td>
<td>' (single quote)</td>
<td>'</td>
</tr>
<tr>
<td></td>
<td>&quot; (double quote)</td>
<td>&quot;</td>
</tr>
<tr>
<td></td>
<td>CR (carriage return)</td>
<td>(blank)</td>
</tr>
<tr>
<td></td>
<td>NL (newline)</td>
<td>\n ('' followed by 'n')</td>
</tr>
<tr>
<td>Type</td>
<td>From</td>
<td>To</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------</td>
<td>----------</td>
</tr>
<tr>
<td>HTML</td>
<td>&amp; (ampersand)</td>
<td>&amp;</td>
</tr>
<tr>
<td></td>
<td>&lt; (less than)</td>
<td>&lt;</td>
</tr>
<tr>
<td></td>
<td>&gt; (greater than)</td>
<td>&gt;</td>
</tr>
</tbody>
</table>

You can also escape HTML using the `getHTMLValue()` function which will enforce all line breaks and escape the characters mentioned above. It can be used as follows:

```java
$(test.getHTMLValue())
```

### Add escaping to a Jelly replacement

You can handle character escaping in Jelly files. XML escaping behavior can be modified only by users with the security_admin role.

### About this task

**Note:** This functionality requires a knowledge of JavaScript, HTML, and Apache Jelly (a Java and XML based scripting and processing engine for turning XML into executable code).

### Procedure

Add a prefix to the `${expression}` or `[$expression]` indicating the escaping to be performed.

```java
${JS:expression}
${HTML:expression}
```

The prefix tells the system to take the result of the expression and escape it before outputting. The escaping may be combined by specifying a comma-separated list of prefixes:

```java
${JS,HTML:expression}
```

### Extensions to Jelly syntax

Apache's Jelly syntax is used to render forms, lists, UI pages, and many other things rendered in ServiceNow.

With Jelly, logic can be embedded within static content and computed values may be inserted into the static content.

**Attention:** This functionality requires a knowledge of Apache Jelly (a Java and XML based scripting and processing engine for turning XML into executable code).
This page from Apache has a summary of the standard Jelly tags: http://commons.apache.org/jelly/tags.html

**Namespaces**

Jelly often includes multiple namespaces when invoking tags.

The "j" namespaces are standard Jelly whereas the "g" namespaces are unique to ServiceNow scripts. For example, the <g:evaluate> tag is supplied by ServiceNow to allow you to compute a value using JavaScript. The standard Jelly tag <j:test> is used to evaluate a condition.

**Phases**

Usually, there are two phases indicated by namespaces <j> versus <j2> and <g> versus <g2>.

The namespaces without the "2" happen in the first phase of processing and these are cached except when used in a UI page. Those with the "2" are never cached. Care must be taken when selecting whether to use phase 1 or phase 2 for efficiency and correct results.

In addition to the namespaces, the syntax used to insert values into static content differs depending on which phase is to supply the value. A dollar with braces surrounding a value inserts the value in phase 1. For example, ${jvar_ref} inserts the value jvar_ref during phase 1 of the jelly process. A dollar with brackets surrounding a value inserts the value in phase 2. For example, ${[jvar_ref]} inserts the value jvar_ref during phase 2. A value surrounded by quotes is treated as a string. For example, ['jvar_ref'] inserts the value jvar_ref as a string during phase 2.

```html
<script>
if (confirm("${gs.getMessage('home.delete.confirm')}"))
...
</script>
<input type="hidden" id="${jvar_name}" name="${jvar_name}" value="${jvar_value}" class="${jvar_class}" />
```

**If tests**

You can use if statements in Jelly scripts.

Testing whether something is true or not can be done as follows:

```xml
<j:if test="${jvar_something}">...do something...</j:if>
<j:if test="${!jvar_something}">...do something...</j:if>
```
The reason this statement works, is that, in Jelly, a term like jvar_something is "truthful" in an if tag if:

1. it is Boolean and true
2. it is a String and = "true", "yes", "on", or "1"

Testing whether something exists can be done as follows:

```xml
<j:if test="${empty(jvar_something)}">...do something...</j:if>
```

The reason this statement works is that the JEXL empty function returns true if its argument is:

1. null
2. an empty string
3. a zero length collection
4. a map with no keys
5. an empty array

⚠️ Note: You cannot mix javascript and jvar variables in a JEXL expression. They must be broken into separate expressions.

**Set If**

Sets a variable to one of two different values depending on whether a test is true or false.

```xml
<g2:set_if var="jvar_style" test="${gs.getPreference('table.compact') != 'false'}" true="margin-top:0px; margin-bottom:0px;" false="margin-top:2px; margin-bottom:2px;" />
```

**<g:insert> versus <g:inline> versus <g:call>**

This page provides a comparative explanation of three tags: `<g:insert>`, `<g:inline>`, and `<g:call>`.

**<g:insert>**

The `<g:insert>` tag inserts a Jelly file into your Jelly in a new context. This means you cannot access the variables previously established in your Jelly.

```xml
<g:insert template="get_target_form_function.xml" />
```
The `<g:inline>` tag inserts a Jelly file into your Jelly in the same context. This means that the inserted Jelly can access the variables you previously established and it can change the values of those variables.

```
<g:inline template="element_default.xml" />
```

The `<g:call>` tag may be used. Your function will only have access to the values passed to it. The Jelly context will look the same after a call as before the call. This means you cannot set a global variable here and read it later. This also means you can't mistakenly set a global variable called "jvar_temp" and overwrite a variable that somebody else was relying on.

Passing values, if needed, is done explicitly by including the name of the parameter on the `<g:call>` line followed by the equal sign followed by the value in quotes:

```
<g:call function="collapsing_image.xml" id="${jvar_section_id}" image="${jvar_cimg}"
    first_section_id="${jvar_first_section_id}" image_alt="${jvar_cimg_alt}" />
```

If values are passed, and you want to have defaults or required parameters, your Jelly referenced in the function must then include a line to declare whether the parameters are required or have a default value:

```
<g:function id="REQUIRED" image="REQUIRED" image_prefix="" image_alt="REQUIRED"/>
```

The example above indicates that 3 of the parameter are required and one parameter is option with a blank default value. Note that if you are not passing values or if you do want to have default or required values, you do not need to include the `<g:function>` line at all. In general, however, you will want to include a `<g:function>` line.

The value can then be referenced in your template by prepending the "jvar_" prefix to the parameter's name:

```
<img id="img.${jvar_id}" src="images/${jvar_image}" alt="${jvar_image_alt}"
    onclick="toggleSectionDisplay('${jvar_id}', '${jvar_image_prefix}', '${jvar_first_section_id}');"/>
```

For `<g:call>`, parameters may also be pass implicitly as a list of named variables in an "arguments" parameter:

```
<g:call function="item_link_default.xml"
    arguments="sysparm_view,ref_parent,jvar_target_text"/>
```

As an alternative to passing variables into the function via separate tag arguments, it is possible to pass a list of variables in a single 'arguments'
argument. All variables identified by name (comma separated) in the argument parameter are re-introduced within the function under the exact same name (e.g. inside the function template, we'd have variables sysparm_view, ref_parent, and jvar_target_text available to us).

The function template may return a value to the calling template using the return attribute. Within the function the jvar_answer variable sets the return value.

```xml
g:call function="item_body_cell_calc_style.xml" arguments="jvar_type" return="jvar_style"/>
```

**<g:evaluate>**

The <g:evaluate> tag is used to evaluate an expression written in Rhino JavaScript and sometimes to set a variable to the value of the expression.

The last statement in the expression is the value the variable will contain.

```xml
g2:evaluate var="jvar_page" jelly="true">
  var page = "";
  var pageTitle = "";
  var pageGR = new GlideRecord("cmn_schedule_page");
  pageGR.addQuery("type", jelly.jvar_type");
  pageGR.query();
  if (pageGR.next()) {
    page = pageGR.getValue("sys_id");
    pageTitle = pageGR.getDisplayValue();
  } 
  page;
</g2:evaluate>
```

```xml
<g2:evaluate var="not_important" expression="sc_req_item.popCurrent()" />
```

**object="true"**

If you would like to have the evaluate return an object (for example an array), use the argument object="true".

```xml
<g2:evaluate object="true" var="jvar_items" expression="SncRelationships.getCMDBViews()" />
```

**jelly="true"**

If you would like to access Jelly variables inside an evaluate, include jelly="true" in the evaluate and add "jelly." before the Jelly variable's name. For example, to access the GlideJellyContext:
Another example of accessing a jvar using the jelly="true" parameter. The value of jvar_h was set previously and we can access it inside the evaluate:

```
${NLBR:jvar_h.getHTMLValue('newvalue')}
```

```g2:evaluate var="jvar_fix_escaping" jelly="true">
  var auditValue = jelly.jvar_h.getHTMLValue('newvalue');
  gs.log("************ " + auditValue);
</g2:evaluate>
```

**copyToPhase2="true"**

If you have a need to take the results of an evaluation that occurs in phase 1 and propagate it to phase 2, use copyToPhase2="true". There is some protection for escaping in this use. For example:

```g:evaluate var="jvar_has_special_inc" copyToPhase2="true">
  var specialInc = gs.tableExists("special_incident");
  specialInc;
</g:evaluate>
```

```
${jvar_has_special_inc}
```

If you do not need to evaluate something, you can do this more directly. Beware of escaping issues here (double quotes in jvar_rows would cause a problem in the example):

```j2:set var="jvar_rows" value="${jvar_rows}"/>
```

```
<g:breakpoint/>
```

This tag can be used to display the current Jelly variables and their values in the log.

Be sure to remove this tag before going to production.

```
<g:ui_form/>
```

This tag defines a form on the UI page.

For example, if your form contained the application_sys_id field:

```
<g:ui_form>
  <p>Click OK to run the processing script.</p>
</g:ui_form>
```
The g:ui_form may benefit greatly from a processing script.

**<g:ui_input_field />**
This tag adds a reference to a UI macro that creates an input field on a page that allows users to input information. The ui_input_field passes a label, name, value, and size into the UI macro.

Here is an example from a UI page:

```html
<g:ui_input_field label="sys_id" name="syid" value="9d385017c611228701d22104cc95c371" size="50"/>
```

**<g:ui_checkbox/>**
This tag puts a user-editable check mark on a page. The name and value are passed into the UI macro.

Here is an example from a table on a UI page:

```html
<table>
  <tr>
    <td nowrap="true">
      <label>Time Card Active:</label>
    </td>
    <td>
      <g:ui_checkbox name="timecard_active" value="${sysparm_timecard_active}"/>
    </td>
  </tr>
</table>
```

**<g:dialog_buttons_ok_cancel/>**
This tag puts buttons on the UI page that run a specified processing script if the tag returns true.

If your UI page contains a form (uses the <g:form> tag), you can submit the form and have the Processing Script run. The Processing Script can naturally access fields on the form. For example, if your form contained the application_sys_id field:

```html
<g:ui_form>
  <p>Click OK to run the processing script.</p>
</g:ui_form>
```
This tag adds a reference to a page that can be referenced by a Processing Script.

The following example creates a reference defined by name, id, and table parameters in the tag:

```xml
<g:ui_reference name="QUERY:active=true^roles=itil" id="assigned_to" table="sys_user" />
```

Then in the Processing Script, reference the name field like this:

```javascript
newTask.assigned_to = request.getParameter("QUERY:active=true^roles=itil");
```

You can specify a reference qualifier, so that the "name" attribute can be unique. The following example creates a reference defined by name, id, and table parameters in the tag. Note: the "columns" attribute only applies to the auto-completer.

```xml
<g:ui_reference name="parent_id" id="parent_id" table="pm_project" query="active=true" completer="AJAXTableCompleter" columns="project_manager;short_description"/>
```

### Ampersand

Ampersands in Jelly can cause you grief because Jelly is XML.

Use `${AMP}` to insert an ampersand in Jelly. If you are writing JavaScript that appears in the HTML part of say a UI page or UI macro that is actually going to run on the browser you are better off putting this code in the "client script" field and that way you can avoid escaping issues. However, if you really must put it in the "HTML" field, you will need to do something like this:

```javascript
ta = ta[1].split('$[AMP]');
```

### And

Use `${AND}` to insert a JavaScript and in Jelly.

For example:

```javascript
if (d ${AND} e)
    var color = d.value;
```

Alternately, in a Jelly test you would use `&amp;`. For example:
Less than

Similar to ampersands, less than (<) signs can also cause problems due to Jelly being XML. This can be resolved by reversing your test such that it is not necessary or by using ${AMP}lt; in place of the less than sign.

```xml
<g2:evaluate var="jvar_text">
    var days = ";
    var selectedDays = '${ref}';
    for (var i = 1; i <= 7; i++) {
        if (selectedDays.indexOf(i.toString()) >= 0) {
            days += gs.getMessage("dow" + i);
            days += " ";
        }
    }
    days;
</g2:evaluate>
```

Many times you can avoid the "less than" operator all together by just using "not equals" which doesn't have escaping issues. For example:

```xml
for (var i=0; i != ta.length; i++) {
}
```

Whitespace

Normally, white space is removed by Jelly. To keep it, you must specify that it not be trimmed.

For example, the following keeps the space after the colon.

```xml
<j2:whitespace trim="false">${gs.getMessage('Did you mean')}: </j2:whitespace>
```

Spaces

To encode a non-breaking space (&nbsp;), you can use $[SP]$.

For example:

```xml
<span id="gsft_domain" style="display: inline">
    ${gs.getMessage('Domain')}:$[SP]
    <span id="domainDD" class="drop_down_element" style="text-decoration: none; color: white">
        $[gs.getMessage("Loading...")]
    </span>
</span>
```
Tracing Jelly

ServiceNow has a feature that allows the evaluation of Jelly to be traced.

The trace is sent to the log. This should only be turned on during debugging as this produces a lot of logging. To turn on the trace, set the property glide.ui.template.trace to true. For example, the following script can be executed to do this:

GlideProperties.set('glide.ui.template.trace', true);

If you want to see your log entries on your web browser at the bottom of each page, navigate to System Diagnostics > Debug Log.

Useful scripts

Scripts that provide useful functionality not included in the core system.

Get a user object

In a business rule or other server script, the gs.getUser() method returns a user object. The user object is an internal representation of the currently logged in user and provides information about the user and various utility functions.

About this task

For a list and description of the available scoped methods for the user object, see GlideUser.

Procedure

1. Retrieve the current user.

   var myUserObject = gs.getUser()

2. Use the getUserByID method to fetch a different user using the user_name field or sys_id on the target record.

   For example:

   var ourUser = gs.getUser();
   gs.print(ourUser.getFirstName()); //print the first name of the user you are currently logged in as
   newUser = ourUser.getUserByID('abel.tuter'); //fetch a different user, using the user_name field or sys_id on the target user record.
   gs.print(newUser.getFirstName()); //first name of the user you fetched above
   gs.print(newUser.isMemberOf('Capacity Mgmt'));
Accessing the workflow scratchpad from business rules

A catalog item has been requested, the attached workflow contains a run script activity that populates a value in the scratchpad. From a business rule running on the requested item, we want to retrieve or set scratchpad values.

Prerequisites
Role required: admin

Name: Access Workflow Scratchpad from Business Rules
Type: Business Rule
Table: sc_req_item (Requested Item)

Description: A catalog item has been requested, the attached workflow contains a run script activity that populates a value in the scratchpad. From a business rule running on the requested item, we want to retrieve or set scratchpad values.

Parameters: n/a

Script:

```javascript
//the run script activity sets a value in the scratchpad
workflow.scratchpad.important_msg = "scratch me";

//get the workflow script include helper
var workflow = new Workflow();

//get the requested items workflow context
//this will get all contexts so you'll need to get the proper one if you have multiple workflows for a record
var context = workflow.getContexts(current);
//make sure we have a valid context
if (context.next()) {
    //get a value from the scratchpad
    var msg = context.scratchpad.important_msg;
    //msg now equals "scratch me", that was set in the run script activity

    //add or modify a scratchpad value
    context.scratchpad.status = "completed";
    //we need to save the context record to save the scratchpad
    context.update();
}
```
Add a field to the service catalog checkout

This is an example of adding a Company field to the checkout below the Requested for field using non-cart layout macros, that is, glide.sc.use_cart_layouts is false.

About this task

This field will then passing the value of that field to the Company field of the Service Catalog Request.

This example makes the following assumptions.

• This example is for an instance using two-step checkout. If two-step checkout is not enabled, enable it before beginning.

• This example populates the Company field on the Service Catalog Request form. If the field does not appear on the form, configure the form before beginning.

Procedure

1. Go to System UI > UI Macros and select servicecatalog_cart_template.
2. Find where there are hidden variables declared and add the following line:
   
   ```html
   <input type="HIDDEN" name="cart_id" id="cart_id" value="${sc_cart.sys_id}" />
   ```

3. Find the following code, which generates the Requested For code:

   ```html
   <tr class="header">
   <td width = "30%">
   ${gs.getMessage('Requested for')}: 
   </td>
   <td width="70%">
   <label for="requestor_location">${gs.getMessage('Deliver to')}:</label>
   </td>
   </tr>
   ```
4. Add the following code afterwards:

```html
<tr class="header">
    <td colspan="2">Company</td>
</tr>
<tr>
    <td>$[SP]</td>
</tr>
<tr>
    <td colspan="2">
        <g2:ui_reference name="core_company" table="core_company" onchange="setCartValue()" />
    </td>
</tr>
<tr>
    <td>$[SP]</td>
</tr>
```

- Note that 'ui_reference' is another macro that defines a reference field. There are several macros for different field types. You can see examples of these field types under System UI -> UI Macros. These macros start with 'ui_'. For this example, the reference field created is named core_company.

5. Now navigate to System UI > UI Pages and select the servicecatalog_checkout_one UI Page. Add this script to the Client script field:
function setCartValue() {
    var newField = gel('core_company');
    var myCart = gel('cart_id');
    var cart_item = new GlideRecord('sc_cart_item');
    cart_item.addQuery('cart', myCart.value);
    cart_item.query();
    if(cart_item.next()) {
        cart_item.hints = '<hints><entry key="sysparm_processing_hint" value="setfield:request.company=" + newField.value + "/"></hints>";
        cart_item.update();
    }
}

For this example, the reference field was called core_company, and the field being populated on the request is company. If different fields are used:

• Find this line: var company = gel('core_company'); and replace core_company with the name of the field in the checkout.

• In the line that starts with 'cart_item.hints' replace 'request.company' with the name of the field to be populated on the request ticket where 'request' is the request being generated and 'company' is the name of the field.

Results
Now, when an item is ordered, the company field appears on the Catalog form:
Add role to every user

Adds a role to every user.

Prerequisites

**Note:** This functionality requires a knowledge of JavaScript.

Role required: admin

In this sample, the role being added is Self Service. To add a different role, simply substitute the desired role for `self_service`.

**Name:** Add Role to Every User

**Type:** Client Script, Background Script

**Table:** sys_user

**Description:** Adds a role to every user. In this sample, the role being added is Self Service. To add a different role, simply substitute the desired role for `self_service`.

**Parameters:**

**Script:**
Assign a catalog item to a group based on a delivery plan task
This assignment rule assigns a service catalog item to the database group if it uses a delivery plan that has a catalog task assigned to the desktop group.

Prerequisites
Role required: admin

⚠️ CAUTION: The customization described here was developed for use in specific instances, and is not supported by ServiceNow Technical Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

Name: Assign Catalog Item to Group Based on Delivery Plan Task
Type: Assignment Rule
Table:
Description: This assignment rule assigns a service catalog item to the database group if it uses a delivery plan that has a catalog task assigned to the desktop group.

Parameters:

Script:
```javascript
//Return catalog items that have no group but do have a delivery plan assigned var ri = new GlideRecord("sc_cat_item"); ri.addQuery("group", "=", null); ri.addQuery("delivery_plan", "!", null); ri.query(); while(ri.next()) { gs.log("Found an item"); //Return tasks that point to the same delivery plan as the above item var dptask = new GlideRecord("sc_cat_item_delivery_task"); dptask.addQuery("delivery_plan", ",", ri.delivery_plan);
```
dptask.query();
while(dptask.next()) {
    gs.log("Found a task");
    var gp = dptask.group.getDisplayValue();
    gs.log(gp);
    //If the task is assigned to desktop, assign the item's group to desktop
    if (dptask.group.getDisplayValue() == "Desktop") {
        ri.group.setDisplayValue("Desktop");
        gs.log("updating " + ri.getDisplayValue());
        ri.update();
        break; } } } }

Change form color on state change
Changes color of a form field of the form on state change. The script can easily be changed to adjust any property of any object on the page accessible via the HTML DOM.

⚠️ CAUTION: The customization described here was developed for use in specific instances, and is not supported by ServiceNow Technical Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

Name: Change Form Color on State Change
Type: Client Script
Table:
Description: Changes color of a form field of the form on state change. The script can easily be changed to adjust any property of any object on the page accessible via the HTML DOM.
Parameters:
Script:

```javascript
function onChange(control, oldValue, newValue, isLoading) {
    var elementID = gel("incident.priority");
    switch(newValue) {
    case "1": elementID.style.backgroundColor = "red"; break;
    case "2": elementID.style.backgroundColor = "tomato"; break;
    case "3": elementID.style.backgroundColor = "orange"; break;
    case "4": elementID.style.backgroundColor = "yellow"; break;
    case "5": elementID.style.backgroundColor = "green"; break;
    default: elementID.style.backgroundColor = "white"; break; } }
```
Create a UI routing action

This solution enables you to create a record with the service desk without knowing whether it is an incident or request item; the service desk can then route the record to the appropriate table.

About this task

Note: Functionality described here requires the Admin role.

To create a UI routing action:

Procedure

1. Create a new table that extends the task table (for example, New Call).
2. Create a module to create a new New Call record.
3. Create any fields that you want on the New Call table.

   The only fields you need are those fields necessary to determine whether the new call should route to an Incident or a Request Item. Ensure that the form contains any fields that you want to pass to the Incident or Request Item. In this example, the following are created on the form:

   - **Requested for** (reference)
   - **Location** (reference)
   - **Call type** (choice with two values--Incident and Request)
   - **Request Item** (reference to the sc_cat_item Item table)

4. Add some UI policies to set a couple of fields to mandatory and hide the Request Item field based on the Call type selection.
5. Remove unnecessary buttons and functionality from the form.
6. Create a new UI Action button. This button redirects the user to either an incident or a request. It also creates the incident record and copies values to the incident and the Request Item form.

   ```javascript
   var reqItem = current.u_item;
   var requestedFor = current.u_requested_for;
   var location = current.location;

   if(current.u_incident_request == 'Incident') {
       //Create a new incident record and redirect to the new incident
       var rec = new GlideRecord('incident');
       rec.initialize();
       rec.caller_id = requestedFor;
   }
   ```

rec.location = location;
rec.insert();
action.setRedirectURL(rec);
}

if(current.u_incident_request == 'Request'){
    //Build the url and route the user to the request item
    var url = ''; 
    if(current.u_item.sys_class_name == 'sc_cat_item_guide'){
        url = 'com.glideapp.servicecatalog_cat_item_guide_view.do?sysparm_initial=true&sysparm_guide='
            + reqItem + '&sysparm_user=' + requestedFor + '&sysparm_location=' + location;
    }else{
        url = 'com.glideapp.servicecatalog_cat_item_view.do?sysparm_id=' + reqItem +
            '&sysparm_user=' +
            requestedFor + '&sysparm_location=' + location;
    }
    action.setRedirectURL(url);
}

7. The Route button in the preceding example passes the Requested for and Location values in the URL to the Request Item form. Ensure that you have variables called requested_for and location on your item, record producer, or order guide that map these values using the following client script. There is a limit as to how much information you can pass, as the URL has a restricted length. Avoid sending information from long text fields using this method.

function onLoad() {
    var url = document.location.toString();
    var userKey = 'sysparm_user=';
    var locKey = 'sysparm_location=';
    var userPosition = url.indexOf(userKey);
    var locPosition = url.indexOf(locKey)
    if (userPosition != -1) {
        var user = url.substr(userPosition+userKey.length, 32);
        g_form.setValue('requested_for',user);
    }
    if (locPosition != -1) {
        var loc = url.substr(locPosition+locKey.length, 32);
        g_form.setValue('location',loc);
    }
}
Custom approval UI macro

This section describes how to create a custom approval UI macro.

⚠️ CAUTION: The customization described here was developed for use in specific instances, and is not supported by ServiceNow Technical Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

Script Name: Custom Approval UI Macro
Type: UI Macro
Description: Here is an option to get more detail out of the My Approvals view of an Execution Plan. This can be done by creating a new UI macro. Navigate to System UI and click UI Macros. First, you will need to rename the existing approval_summarizer_sc_task to something like approval_summarizer_sc_task_old and deactivate it. Then you will need to create a new one using the same name (approval_summarizer_sc_task). The name should basically tell you what the macro does and what it applies to. In this case, we’re replacing an existing one so we decided to re-use the existing name.

Then you should copy the xml script at the bottom of this article into the xml code window in the new UI macro. This is great way to give some detail to an approver when you are doing line item approvals via approval tasks within the Service Catalog Execution Plans.
The old way

This is the view you see in My Approvals when using an approval task via the old method.

My Approvals (old way)

Notice there is not much detail telling the approver what they are actually approving. You can see the short description of the task but not much around what the item is.

The new way

This is the view you will see if you use the xml script below in place of the OOB (out-of-box) UI macro.

My Approvals

Using this method you can see details much like the request approval. You have a link into the item ordered, a short description (which contains the ability to expand the variables from the item), price, quantity and the total price. This helps the approver in that it shows more detail. They can now see what they are actually approving.

Script:

```xml
<?xml version="1.0" encoding="utf-8" ?>
<j:jelly trim="true" xmlns:j="jelly:core" xmlns:g="glide" xmlns:j2="null" xmlns:g2="null">
```

<td></td>
</tr>
</tbody>
</table>

<j:set var="jvar_line_num" value="0" />
<tr width="100%">
    <td width="100%">
        <table width="100%">
            <tr class="header">
                <td colspan="2">${sc_req_labels.number.sys_meta.label}</td>
                <td>${sc_req_labels.description.sys_meta.label}</td>
                <td>${sc_req_labels.price.sys_meta.label}</td>
                <td>${sc_req_labels.quantity.sys_meta.label}</td>
                <td>${gs.getMessage('Total')}</td>
            </tr>
            <j:set var="jvar_item_price" value="${sc_task.request_item.price * sc_task.request_item.quantity}"/>
            <j:set var="jvar_overall_total" value="${jvar_overall_total + jvar_item_price}"/>
            <j:set var="jvar_line_color" value="odd"/>
            <j:set var="jvar_line_num" value="${jvar_line_num + 1}"/>
            <j:if test="${jvar_line_num % 2 == 0}">
                <j:set var="jvar_line_color" value="even"/>
            </j:if>
            <g:evaluate var="ni" expression="'">
                var smart_description =
                sc_task.request_item.cat_item.short_description;
                if (smart_description == null || smart_description == '')
                    smart_description = 'undefined';
                smart_description = sc_task.request_item.cat_item.name;
            '</ni>
    </td>
</tr>
Display field messages

Rather than use JavaScript `alert()`, for a cleaner look, you can display an error on the form itself. The methods `showFieldMsg()` and `hideFieldMsg()` can be used to display a message just below the field itself.

`showFieldMsg` and `hideFieldMsg` are methods that can be used with the `g_form` object.
These methods are used to change the form view of records (Incident, Problem, and Change forms). These methods may also be available in other client scripts, but must be tested to determine whether they work as expected.

When a field message is displayed on a form on load, the form scrolls to ensure that the field message is visible. Ensuring that users do not miss a field message because it was off the screen.

The global property `glide.ui.scroll_to_message_field` controls automatic message scrolling when the form field is offscreen (scrolls the form to the control or field).

### Method Detail

<table>
<thead>
<tr>
<th>Method Detail</th>
<th>Parameters</th>
<th>Example</th>
</tr>
</thead>
</table>
| `showFieldMsg(input, message, type, [scrollform])` | - input — name of the field or control  
- message — message you would like to appear  
- type — 'info', 'error', or 'warning'; defaults to info if not supplied  
- scroll form — (optional) Set `scrollForm` to false to prevent scrolling to the field message offscreen | **Error Message**  
```
g_form.showFieldMsg('impact','Low impact not allowed with High priority','error');
```

<table>
<thead>
<tr>
<th>Impact:</th>
<th>3 - Low</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="https://example.com/warning.png" alt="Warning" /></td>
<td>Low impact not allowed with High priority</td>
</tr>
</tbody>
</table>

**Informational Message**  
```javascript
//or this defaults to info type  
//g_form.showFieldMsg('impact','Low impact response time can be one week');
```

<table>
<thead>
<tr>
<th>Impact:</th>
<th>3 - Low</th>
</tr>
</thead>
<tbody>
<tr>
<td>✔️</td>
<td>Low impact response time can be one week</td>
</tr>
</tbody>
</table>
## Method Detail (continued)

<table>
<thead>
<tr>
<th>Method Detail</th>
<th>Parameters</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>hideFieldMsg(input)</td>
<td>• input — name of the field or control</td>
<td>Removing a Message</td>
</tr>
<tr>
<td></td>
<td>• clearAll — (optional) boolean parameter</td>
<td></td>
</tr>
<tr>
<td></td>
<td>indicating whether to clear all messages.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If true, all messages for the field are cleared.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If false or empty, only the last message is</td>
<td></td>
</tr>
<tr>
<td></td>
<td>removed</td>
<td></td>
</tr>
</tbody>
</table>

### Removing a Message

```javascript
//this will clear the last message printed to the field
g_form.hideFieldMsg('impact');
```

## Legacy support

The `showErrorBox()` and `hideErrorBox()` are still available but simply call the new methods with type of error. You should use the new methods.

## GSLog

GSLog is a script include that simplifies script logging and debugging by implementing levels of log output, selectable by per-caller identified `sys_properties` values.

### Log level

Logs can be at the level of Debug, Info, Notice, Warning, Err, or Crit (after BSD syslog.h and followers). The default logging level is Notice, so levels should be chosen accordingly.

### Where to use

Use for any server-side script where you want to implement event logging.
Available Methods

**initialize(traceProperty, caller)**
Called by the Prototype JavaScript Framework during object creation to initialize a new instance of this class. Provide the input parameters, but do not call this method directly.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>traceProperty</td>
<td>String</td>
<td>System property that contains a value indicating the level at or above which messages will be written to the log.</td>
</tr>
<tr>
<td>caller</td>
<td>String</td>
<td>Name of the script calling the logger.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

```javascript
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
```

**logDebug(msg)**
Logs debug events.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to write to the log</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Example**
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.logDebug("This is a debug message");

Output:

*** Script [TaskSLA]: This is a debug message

logInfo(msg)
Logs information events.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to write to the log</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.logInfo("This is an info message");

logNotice(msg)
Logs notice events.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to write to the log</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.logNotice("This is a notice message");
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");

// Output:

*** Script [TaskSLA]: This is a notice

### logWarning(msg)

Logs warning events.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to write to the log</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

#### Example

```javascript
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");

// Output:

*** Script [TaskSLA]: This is a warning message
```

### logErr(msg)

Logs error events.

#### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to write to the log</td>
</tr>
</tbody>
</table>

#### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>
Example

```javascript
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.logErr("This is an error message");
```

Output:

```text
*** Script [TaskSLA]: This is an error message
```

**logCrit(msg)**

Logs critical events.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to write to the log</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```javascript
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.logCrit("This is a critical message");
```

Output:

```text
*** Script [TaskSLA]: This is a critical message
```

**logAlert(msg)**

Logs alert events.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to write to the log</td>
</tr>
</tbody>
</table>
### logAlert(msg)
Logs an alert event.

**Example**

```javascript
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.logAlert("This is an alert");
```

**Output:**
```
*** Script [TaskSLA]: This is an alert
```

### logEmerg(msg)
Logs emergency events.

**Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to write to the log</td>
</tr>
</tbody>
</table>

**Returns**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

```javascript
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.logEmerg("This is an emergency message");
```

**Output:**
```
*** Script [TaskSLA]: This is an emergency message
```

### log(level, msg)
Logs a message at the specified level.

**Example**

```javascript
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.log("This is a message");
```

**Output:**
```
*** Script [TaskSLA]: This is a message
```
### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>level</td>
<td>String</td>
<td>Log level</td>
</tr>
<tr>
<td>msg</td>
<td>String</td>
<td>Message to write to the log</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

### Example

```javascript
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.log("debug", "debug message");
```

#### getLevel(level)

Returns the log level.

### Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>level</td>
<td>String</td>
<td>Optional. Log level</td>
</tr>
</tbody>
</table>

### Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>Log level</td>
</tr>
</tbody>
</table>

### Example

```javascript
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.setLevel("debug");
gs.print(gl.getLevel());
```

**Output:**

```plaintext
*** Script: debug
```

#### setLevel(level)

Sets the log level.
Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>level</td>
<td>String</td>
<td>Log level to set</td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td></td>
</tr>
</tbody>
</table>

Example

```
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.setLevel("debug");
```

debugOn()

Determined if debug is turned on.

Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Returns

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boolean</td>
<td>If true, debug is on; if false, debug is off.</td>
</tr>
</tbody>
</table>

Example

```
var gl = new GSLog("com.snc.sla.tasksla.log", "TaskSLA");
gl.setLevel("debug");
gs.print(gl.debugOn());
```

Output:

```
*** Script : true
```

Modify a GlideDateTime field value

This example demonstrates how to modify a GlideDateTime field value using a script.
Name: Modify a GlideDateTime Field Value
Type: A server side script that accesses a GlideDateTime field.
Table: N/A
Description: Given a GlideDateTime field or script object, show a variety of ways to easily modify value. The same concept also applies to the GlideDate object.
Parameters: N/A

Script:
```javascript
//You first need a GlideDateTime object
//this can be from instantiating a new object "var gdt = new GlideDateTime()"
//or getting the object from a GlideDateTime field
//getting the field value (for example: var gdt = current.start_date) only returns the string value, not the object
//to get the object use var gdt = current.start_date.getGlideObject();
//now gdt is a GlideDateTime object
var gdt = current.start_date.getGlideObject();

//All methods can use negative values to subtract intervals

//add 1 hour (60 mins * 60 secs)
gdt.addSeconds(3600);

//add 1 day
gdt.addDaysLocalTime(1);

//subtract 1 day
gdt.addDaysLocalTime(-1);

//add 3 weeks
gdt.addWeeksLocalTime(3);

//subtract 6 months
gdt.addMonthsLocalTime(-6);

//add 1 year, representing the date and time using the UTC timezone instead of the local user's timezone.
gdt.addYearsUTC(1);

//set the value of the GlideDateTime object to the current session timezone/format
GlideSession.get().setTimeZoneName('US/Eastern');
gdt.setDisplayValue('2018-2-28 00:00:00');
gs.info('In ' + GlideSession.get().getTimeZoneName() + " : " + gdt.getDisplayValue());
```
Sample ASP.NET with C Sharp redirect with cookies

This sample ASP .NET code creates a simple authentication portal and passes an unencrypted HTTP header as a cookie.

⚠️ Note: Functionality described here requires the Admin role.

⚠️ Note: Cookies are domain specific and cannot be used across different network domains. The only domain that can read a cookie is the domain that sets it. It does not matter what domain name you set. If you do not have an option of your SSO portal being in the same network domain as your ServiceNow instance (for example, in an on-premisis deployment, an alternative is to pass the SSO token using URL GET or POST parameters.

This sample assumes:

- The web server supports ASP .NET and C#
- The target ServiceNow instance is https://<instance name>.service-now.com/
- SiteMinder or another single sign-on application has pre-authenticated the user
- The target ServiceNowinstance expects an HTTP header of SM_USER

Change the ASP code to redirect users to the proper ServiceNow instance.

```html
<html xmlns="http://www.w3.org/1999/xhtml" >
<head runat="server">
    <title>Portal Page Login</title>
    <%- --
        <meta http-equiv="REFRESH" content="0;url=https://<instance name>.service-now.com/"--%>
    </%- --

</head>
<body>
    <form id="form1" runat="server">
        <h2><b> Portal Page Login </b></h2>
        <hr style="position: static" />
        <br />
        <asp:Label ID="Label2" runat="server" Font-Size="Larger" Height="21px" Style="position: static"
            Text="Instance URL:" Width="113px"></asp:Label>
        <asp:TextBox ID="urlBox" runat="server" Font-Size="Large" Style="position:
            static"></asp:TextBox><br />
        <br />
```
The following C# code handles the `OnClick` button event for the form. The code:

- Creates the cookie “SM_USER”
- Performs a redirect to the URL specified on the ASP form.

Change the C# code to create the proper cookie name.

```csharp
using System;
using System.Data;
using System.Configuration;
```
using System.Web;

public partial class _Default : System.Web.UI.Page
{
    protected void Page_Load(object sender, EventArgs e)
    {
    }
    
    protected void Button1_click(object sender, EventArgs e)
    {
        try
        {
            HttpCookie myCookie = new HttpCookie("SM_USER");
            myCookie.Value = userNameBox.Text;
            Response.Cookies.Add(myCookie);
            Response.Redirect(urlBox.Text);
        }
        catch
        {}
    }
}

Useful approval assignment scripts

This is a searchable version of the useful approval and assignment scripts.

⚠️ CAUTION: The customization described here was developed for use in specific instances, and is not supported by ServiceNow Technical Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

For an easy-to-navigate version, visit the Useful Scripts portal.

Assign a group for ESS requests

Type: Assignment Rule

Description: This script automatically assigns a group for all ESS Requests.

Script example:

```csharp
if(current.opened_by.roles=""){
    current.assignment_group.setDisplayValue('Network');
    current.update();
}
```

Assign Catalog Item to Group Based on Delivery Plan Task
Type: Assignment Rule

Description: This assignment rule assigns a service catalog item to the database group if it uses a delivery plan that has a catalog task assigned to the desktop group.

```javascript
//Return catalog items that have no group but do have a delivery plan assigned
var ri = new GlideRecord("sc_cat_item");
ri.addQuery("group","=" ,null);
ri.addQuery("delivery_plan","!=" ,null);
ri.query();
while(ri.next()){
    gs.log("Found an item");
    //Return tasks that point to the same delivery plan as the above item
    var dptask = new GlideRecord("sc_cat_item_delivery_task");
dptask.addQuery("delivery_plan","=" ,ri.delivery_plan);
dptask.query();
    while(dptask.next()){
        gs.log("Found a task");
        var gp = dptask.group.getDisplayValue();
        gs.log(gp);
        //If the task is assigned to desktop, assign the item's group to desktop
        if(dptask.group.getDisplayValue()=="Desktop"){
            ri.group.setDisplayValue("Desktop");
            gs.log(" updating "+ ri.getDisplayValue());
            ri.update();
            break;}}
}
```

Assign items with one task

Type: Assignment Rule

Description: Automatically assigns any catalog items with only one task associated to a particular group.

```javascript
//Get the catalog item for the current requested item
var scCatItem = new GlideRecord("sc_cat_item");
if(scCatItem.get('sys_id', current.cat_item)){
    // If the catalog item already has an assignment group or if using workflow we don't need to make an assignment
    if(!scCatItem.delivery_plan.nil() && scCatItem.group.nil()){)
        var dpTask = new GlideRecord("sc_cat_item_delivery_task");
dpTask.addQuery("delivery_plan","=" ,scCatItem.delivery_plan);
dpTask.query();
        if(dpTask.getRowCount()==1 && dpTask.next()){
            // Check that there is only 1 record in the GlideRecord
            dpTask.group;}}}
```

Assignment based on workload

Type: Business Rule
Description: Populate the assigned to based on the assignment group member who has the least amount of active incidents.

Parameters:

- **order**: >1000 if you want to execute after assignment rules
- **condition**: current.assigned_to == " & current.assignment_group != "
- **when**: before, insert/update

```javascript
var assignTo = getLowestUser();
gs.addInfoMessage("assigning to is " + assignTo);
current.assigned_to= assignTo;

function getLowestUser(){
    var userList =new Array();
    var cg =new GlideRecord('sys_user_grmmember');
    cg.addQuery('group', current.assignment_group);
    cg.query();
    while(cg.next()){  
        var tech = cg.user.toString();
        var cnt = countTickets(tech);
        gs.addInfoMessage("Tech counts " + cg.user.name + ' ' + cnt + ' ' + tech);
        userList.push({ sys_id: tech, name: cg.user.name, count: cnt });
    }
    for(var i=0; i < userList.length; i++){  
        gs.addInfoMessage(userList[i].sys_id + " " + userList[i].name + " " + userList[i].count);
    }
    userList.sort(function(a, b){
        gs.addInfoMessage("Sorting: " + a.sys_id + "(" + a.count + ");" + b.sys_id + "(" + b.count + ");
        return a.count - b.count;
    });
    if(userList.length<=0)return"";
    return userList[0].sys_id;
}

function countTickets(tech){
    var ct =new GlideRecord('incident');
    ct.addQuery('assigned_to',tech);
    ct.addQuery('active',true);
    ct.query();
    return ct.getRowCount();
}
```

Run assignment rules when category is changed

Type: Client script
Table: Incident

Description: This example is an onChange client script on the category field within Incident. Note: this script used to use synchronous AJAX (asynchronous behavior is specified by the third parameter of the ajaxRequest call). The implementation below uses asynchronous AJAX. The drawback of using the synchronous version is that a network response problem could cause the browser to hang.

```javascript
// Make an AJAX request to the server to get who this incident would be
// assigned to given the current values in the record. This runs the assignment
// rules that have been defined in System Policy and returns the assigned_to and
// the assignment_group

function onChange(control, oldValue, newValue, isLoading){
    if(isLoading){return;
    // No change, do not do anything
    }

    // Construct the URL to ask the server for the assignment
    var url = "xmlhttp.do?sysparm.processor=AJAXAssignment&sys_target=incident";
    var uv = gel('sys_uniqueValue');
    if(uv){
        url += '&sys_uniqueValue=' + uv.value;
    // Make the AJAX request to the server and get the response
    var serial = g_form.serialize();
    // get all values currently assigned to the incident
    var response = ajaxRequest(url, serial, true, responseFunc);
}

// This callback function handles the AJAX response.
function responseFunc(response){
    var item = response.responseXML.getElementsByTagName("item")[0];
    // Process the item returned by the server
    if(item){
        // Get the assigned_to ID and its display value and put them on the form
        var name = item.getAttribute("name");
        var name_label = item.getAttribute("name_label");
        if(name_label && name){
            g_form.setValue('assigned_to', name, name_label);
        } else{
            g_form.setValue('assigned_to', '', '');
        // Get the assignment_group ID and its display value and put them on the form
        var group = item.getAttribute("group");
        var group_label = item.getAttribute("group_label");
        if(group_label && group){
```
Custom approval UI macro

Type: UI macro

The following option illustrates how to obtain more detail from the My Approvals view of an Execution Plan by creating a new UI Macro.

- **Navigate to System UI and click UI Macros.**
- **Rename the existing “approval_summarizer_sc_task” to something like “approval_summarizer_sc_task_old” and deactivate it.**
- **Create a new one using the same name (“approval_summarizer_sc_task”). The name should basically tell you what the macro does and to what it applies. In this case, we’re replacing an existing one so we decided to re-use the existing name.**

Then copy the xml script at the bottom of this article into the xml code window in the new UI Macro. This is great way to give some detail to an approver when you are doing line item approvals using approval tasks within the Service Catalog Execution Plans.

**Different ways**

**Old way**

This is the view you see in My Approvals when using an approval task using the old method.
Notice there is not much detail telling the approver what they are actually approving. You can see the short description of the task but not much information about the item.

**New way**

This is the view you will see if you use the xml script below in place of the OOB (out-of-box) UI Macro.

Using this method you can see details much like the request approval. You have a link into the item ordered, a short description (which contains the ability to expand the variables from the item), price, quantity and the total price. This helps the approver in that it shows more detail. They can now see what they are actually approving.

**Useful field scripts**

This is a searchable version of the useful field customization scripts.

⚠️ **CAUTION:** The customization described here was developed for use in specific instances, and is not supported by ServiceNow Technical Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

For an easy-to-navigate version, visit the Useful Scripts portal.
AKA Incident Template, Auto Assignments, Quick Calls, Call Script, Auto Populate

Let's say you want to auto-fill your Short Description based on the selected Subcategory. First, create a lookup table, then populate the key field, in this case the Subcategory and the auto-filled field, Short Description. So let's say your table had a record with Subcategory = Password and Short Description = Password Reset. When the user selects the Subcategory of Password on the Incident form, a client script looks up the matching record and sets Short Description equal to Password Reset.

Client script settings... Type = onChange, Table name = incident, Field name = Subcategory

```javascript
function onChange(control, oldValue, newValue, isLoading){
  if(isLoading){return;}
  var newrec = gel('sys_row');
  //Check if new record
  if (newrec.value == -1) {
    var lookup = new GlideRecord('u_short_desc_lookup');
    lookup.addQuery('u_subcategory', g_form.getValue('subcategory'));
    lookup.query();
    var temp; //temp var - reusable
    if(lookup.next()){
      temp = lookup.u_short_description;
      if(null != temp) {
        //Set the form value from lookup if there is a lookup value
        g_form.setValue('short_description', temp);
      } else {
        g_form.setValue('short_description','');
      }
    } else {
      //If a lookup record does not exist based on lookup.addQuery
      //Then set to UNDEFINED or NULL depending on type
      g_form.setValue('short_description','');
    }
  }
}
```

You could populate multiple fields or even pull Call Script questions into the Comments field so call center personnel gather good information to pass on to a technician. There are already Assignment Rules, Templates, and Wizards built in that perform similar functions.

Disable HTML tags in descriptions
Description: This code disables HTML tags in descriptions and short descriptions
by substituting the tags with harmless versions that won't execute.
doit();

function doit(){
var desc = current.description.toString();
var shdesc = current.short_description.toString();
if(desc.indexOf('script>')>-1|| shdesc.indexOf('script>')>-1){
desc = desc.replace(/<script>/g,"(script)");
current.description = desc.replace(/<\/script>/g,"(\/script)");
shdesc = shdesc.replace(/<script>/g,"(script)");
current.short_description = shdesc.replace(/<\/script>/g,"(\/script)");}
}

Eliminate leading and trailing spaces in fields
Table: sys_user
Description: This example of the script trims trailing and leading spaces in the
FirstName and LastName fields of sys_user.
doit();

function doit(){
var now_GR =new GlideRecord('sys_user');
gr.query();
while(gr.next()){
if((gr.first_name.toString().length!=
gr.first_name.toString().trim().length)||(gr.last_name.toString().length!=
gr.last_name.toString().trim().length)){
gr.first_name= gr.first_name.toString().trim();
gr.last_name= gr.last_name.toString().trim();
gr.autoSysFields(false);
gr.update();}}
}

Make a field label flash
Type: Client script
Description: The following example is for the number field on incident. The label
will flash for two seconds:
g_form.flash("incident.number","#FFFACD",0);

The arguments for the flash method are as follows:

4574

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries.
Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.


1. `tablename.fieldname`

2. RGB color or acceptable CSS color like "blue" or "tomato"

3. integer that determines how long the label will flash:

   - Use 2 for a 1-second flash
   - Use 0 for a 2-second flash
   - Use -2 for a 3-second flash
   - Use -4 for a 4-second flash

Do not specify this argument if you want the field label simply colored the specified color.

**Make field label bold**

Type: Client script

Description: This script makes the label of a particular field (in this case, **Short Description** on the **Incident Table**) bold.

```javascript
function onLoad(){
    var l = g_form.getLabel('incident.short_description');
    l.style.fontWeight = 'bold';}
```

**Make fields read-only**

Type: Client script

Table: Incident

Description: This onLoad client script makes fields read-only. For this example, the script makes the following fields on the Incident table read-only: **Incident state**, **Impact**, **Urgency**, **Priority**, **Configuration item**, and **Assigned to**. It also removes the magnifying glass for the read-only Reference Fields (**Configuration item** and **Assigned to**).

```javascript
function onLoad(){
    var incidentState = g_form.getValue('incident_state');
    if( incidentState == '6'|| incidentState == '7'){
        g_form.setReadonly('incident_state',true);
        g_form.setReadonly('impact',true);
        g_form.setReadonly('urgency',true);
        g_form.setReadonly('priority',true);
        g_form.setReadonly('cmdb_ci',true);
        g_form.setReadonly('assigned_to',true);}}
```

**Set current date/time in field**
Type: Client script

Description: You can use the following two lines to set the current date and
time in a date/time field. This bypasses the problem of getting the value into the
proper format and proper timezone.

```javascript
var ajax = new GlideAjax('MyDateTimeAjax');
ajax.addParam('sysparm_name','nowDateTime');
ajax.getXML(function(){
    g_form.setValue('put your field name here', ajax.getAnswer());});
```

For more information on running server side scripts with the client, refer to
GlideAjax.

System script include

```javascript
// Be sure the "Client callable" checkbox is checked

var MyDateTimeAjax = Class.create();
MyDateTimeAjax.prototype = Object.extendsObject(AbstractAjaxProcessor, {
    nowDateTime:function(){
        return gs.nowDateTime();}});`
Modify GlideDateTime field value

Type: A server side script that accesses a GlideDateTime field.

Description: Given a GlideDateTime field or script object, show a variety of ways to easily modify value. The same concept also applies to the GlideDate object.

//You first need a GlideDateTime object
//this can be from instantiating a new object "var gdt = new GlideDateTime()"
//for getting the object from a GlideDateTime field
//getting the field value (for example: var gdt = current.start_date)
//only returns the string value, not the object
//to get the object use var gdt = current.start_date.getGlideObject();
//now gdt is a GlideDateTime object
var gdt = current.start_date.getGlideObject();

//All methods can use negative values to subtract intervals

//add 1 hour (60 mins * 60 secs)
gdt.addSecondsLocalTime(3600);

//add 1 day
gdt.addDaysLocalTime(1);

//subtract 1 day
gdt.addDaysLocalTime(-1);
Useful scheduling scripts

A business rule script specifies the actions that the business rule takes. Scripts commonly include predefined global variables to reference items in your system, such as the current record. Global variables are available to all business rules.

⚠️ **CAUTION:** The customization described here was developed for use in specific instances, and is not supported by ServiceNow Technical Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

Calculate duration given a schedule

Type: Before update/insert business rule

Table: Incident

Description: A Business Duration calculates the Open to Close duration on an incident based on the particular Creating and using schedules. If there is no schedule specified, the script will simply use the first schedule returned by the query.

Script example:

The example below sets the resolved duration when the incident state moves to resolved.

```javascript
if(current.incident_state==6){
  var dur = calcDurationSchedule(current.opened_at, current.sys_updated_on);
  current.u_resolved_duration= dur;
}

function calcDurationSchedule(start, end){
  // Get the user
  var usr = new GlideRecord('sys_user');
  // Other code...
```

© 2021 ServiceNow, Inc. All rights reserved.
usrgef(gs.getUserID());
// Create schedule - pass in the sys_id of your standard work day schedule and pass in
the users timezone
var sched = new GlideSchedule('08fcd0830a0a0b2600079f56b1adb9ae',usr.time_zone);
// Get duration based on schedule/timezone
return(sched.duratiom(start.getGlideObject(), end.getGlideObject()));}

Check upcoming termination dates

Type: Scheduled script

Description: This script checks nightly for termination dates on contracts coming
up in 90, 50, or 10 days (depending on the contract duration field).

Script example:

function contractNoticeDue(){
 var now_GR = new GlideRecord("contract");
 gr.addQuery("u_contract_status","Active");
 gr.query();
 while(gr.next()){  
  if((gr.u_termination_date<= gs.daysAgo(-90))&&(gr.u_contract_duration=="Long")){
   gr.u_contract_status="In review";
  }elseif((gr.u_termination_date<= gs.daysAgo(-50))&&(gr.u_contract_duration=="Medium")){
   gr.u_contract_status="In review";
  }elseif((gr.u_termination_date<= gs.daysAgo(-10))&&(gr.u_contract_duration=="Short")){
   gr.u_contract_status="In review";
  }
  gr.update();
}
}

Use scripts in business rules to accomplish common tasks such as:

- Comparing two date fields.
- Parsing XML payloads.
- Aborting a database action in a business rule.

With scripts, you can also:

- Specify the operation that triggers the business rule.
- Use the scratchpad with display business rules to change form values just
  before a user loads the form.
- Use the OR condition like you would in a condition builder.

You can also utilize the system’s scripting functionality available for server-side
scripts.
You can use options on the Business Rules form to build conditions, set field values, and display alert messages without needing to write a script.

**Abort a database action in a business rule**

During a before business rule script, you can cancel or abort the current database action using the current.setAbortAction(true) method.

For example, if the before business rule is executed during an insert action, and you have a condition in the script that calls current.setAbortAction(true), the new record stored in current is not created in the database.

**Add autofill functionality**

Add autofill functionality is also called incident template, auto assignments, quick calls, call script, or auto populate.

Let's say you want to auto-fill your **Short Description** based on the **Subcategory** selected. First, create a lookup table, then populate the key field, in this case **Subcategory** and the auto-filled field, **Short Description**. So let's say your table had a record with **Subcategory** = Password and **Short Description** = Password Reset. When the user selects the subcategory of Password on the Incident form a client script looks up the matching record and sets short description equal to Password Reset. Client script settings... **Type** = onChange, **Table name** = incident, **Field name** = Subcategory.

```javascript
function onChange(control, oldValue, newValue, isLoading) {
    if (isLoading) { return; }
    var newrec = gel('sys_row');
    //Check if new record
    if (newrec.value == -1) {
        var lookup = new GlideRecord('u_short_desc_lookup');
        lookup.addQuery('u_subcategory', g_form.getValue('subcategory'));
        lookup.query();
        var temp; //temp var - reusable
        if (lookup.next()) {
            temp = lookup.u_short_description;
            if (null != temp) { //Set the form value from lookup if there is a lookup value
                g_form.setValue('short_description', temp);
            } else {
                g_form.setValue('short_description', "" );
            }
        } else {
            //If a lookup record does not exist based on lookup.addQuery
            //Then set to UNDEFINED or NULL depending on type
            g_form.setValue('short_description', "");
        }
    }
}
```

You could populate many fields or even pull in call script questions into the Comments field so call center personnel gather good information to pass on to a technician. There are already Assignment Rule, Templates and Wizards built in that perform similar functions.

**Example script: A default before-query business rule**

You can use a query business rule that executes before the database query is made to prevent users from accessing certain records.

⚠️ **CAUTION:** The customization described here was developed for use in specific instances, and is not supported by ServiceNow Technical Support. This method is provided as-is and should be tested thoroughly before implementation. Post all questions and comments regarding this customization to our community forum.

Consider the following example from a default business rule that limits access to incident records.

### Default business rule limits access to incident records

<table>
<thead>
<tr>
<th>Name</th>
<th>Table</th>
<th>When</th>
</tr>
</thead>
<tbody>
<tr>
<td>incident query</td>
<td>Incident</td>
<td>before, query</td>
</tr>
</tbody>
</table>

**Example script**

This example prevents users from accessing incident records unless they have the itil role are listed in the Caller or Opened by field. So, for example, when self-service users open a list of incidents, they can only see the incidents they submitted.

```javascript
if(!gs.hasRole("itil")&& gs.isInteractive()){  
  var u = gs.getUserID();  
  var qc = current.addQuery("caller_id", u).addOrCondition("opened_by", u).addOrCondition("watch_list","CONTAINS", u);  
  gs.print("query restricted to user: "+ u);  
}
```

⚠️ **Note:** You can also use access controls to restrict the records that users can see.

**Schedule script for weekdays**

Type: Business Rules/Client Scripts
This script schedules the script for weekdays. Insert any script where it says "Your Script Here."

```javascript
var go = 'false';
var now = new Date();

// Correct time zone, which is by default GMT -7
now.setHours(now.getHours() + 8);
var day = now.getDay();

// No go on Saturday or Sunday
if (day != 0 && day != 6) {
    // (your script here)
}
```

### Set date field according to current date

This script sets a date field depending on the current day of the week. In this example, if the day is Monday through Wednesday, it sets the date to this coming Monday; otherwise it sets the date field to next Monday.

```javascript
function setCabDate() {
    var today = new Date();
    var thisDay = today.getDay();
    // returns 0 for Sunday, 1 for Monday, etc. thru 6 for Saturday.
    var thisMon = new GlideDateTime();
    thisMon.setDisplayValue(gs.beginningOfThisWeek());
    var nextMon = thisMon.getNumericValue();
    nextMon += (1000 * 60 * 60 * 24 * 7);

    if ((thisDay < 4) && (thisDay > 0)) {
        // if today is Mon thru Wed (thisDay = 1, 2, or 3), set cab to this coming Monday.
        current.u_req_cab_rev_date.setDateNumericValue(thisMon.getNumericValue());
    } else if ((thisDay >= 4) || (thisDay == 0)) {
        // if today is Thurs thru Sun (thisDay = 4, 5, 6, or 0), set cab to next Monday.
        current.u_req_cab_rev_date.setDateNumericValue(nextMon);
    }
}
```

To validate the input of all date/time fields, you can use the following in a validation script ([System Definition > Validation Scripts](#)). Because the date/time format is hard coded in this script, it must match your instance's date/time format. If your instance's date/time format changes, you must update your validation script.
Set the validation script’s type to *Date/Time*. Then, with this validation script, if a user enters an incorrect format in a date/time field, they will receive an error message.

```javascript
function validate(value){
  // empty fields are still valid dates
  if(!value)returntrue;

  // We "should" have the global date format defined always defined. but there's always that
  // edge case...
  if(typeof g_user_date_time_format !=='undefined')return isDate(value,
    g_user_date_time_format);

  // if we don't have that defined, we can always try guessing
  return parseDate(value)!==null;}
```

### Date/time validation

![Validation Script](image)

**Sample ASP Script for unencrypted single sign-on**

This sample ASP .NET code creates a simple authentication portal and passes an unencrypted HTTP header as a URL parameter.

This sample assumes:

- The web server supports ASP .NET
- The target instance is `https://<instance name>.service-now.com/`
• SiteMinder or another single sign-on application has pre-authenticated the user
• The target instance expects an HTTP header of SM_USER

Change the ASP code to redirect users to the proper instance and create the proper HTTP header.

```html
<html xmlns = "http://www.w3.org/1999/xhtml" > <head runat = "server" > <title >Portal Page Login </title > </head > <body > <form id = "form1"  runat = "server" > <h2 >Portal Page Login </h2 > <hr style = "position: static" / > <br / > <asp:Label ID = "Label2"  runat = "server"  Font-Size = "Larger" Height = "21px" Style = "position: static"; Text = "Instance URL:" Width = "113px" ><br /> <asp:TextBox ID = "urlBox"  runat = "server"  Font-Size = "Large" Style = "position: static;" ><br /></asp:TextBox> <br / > <br / > <asp:Label ID = "Label1"  runat = "server"  Font-Size = "Larger" Height = "17px" Style = "position: static;" Text = "User Id:" Width = "113px" ><br /> <asp:TextBox ID = "userNameBox" runat = "server" Font-Size = "Large" Style = "position: static;" ><br /></asp:TextBox> <br / > <br / > <asp:Button ID = "Button1"  runat = "server" Height = "39px" Style = "position: static;" Text = "Ok" Width = "88px" OnClick = "go_to" / > </form > </body > </html >
```
To validate the input of all date/time fields, you can use the following in a validation script (System Definition > Validation Scripts).

Because the date/time format is hardcoded in this script, it must match your instance's date/time format. If your instance's date/time format changes, you must update your validation script.

Set the validation script's type to "glide_date_time". Then, with this validation script, if a user enters an incorrect format in a date/time field, they will receive an error message.

```
function validate (value ) { if ( !value ) { return true ; } return (getDateFromFormat (value , 'yyyy-MM-dd HH:mm:ss' ) != 0 ) ; }
```
Calculating durations

Often you may need to provide users with a way to specify when a task or process is due. Using the DurationCalculator script include, you can calculate the due date, using either a simple duration or relative duration.

For information on schedules, which you can use as inputs to DurationCalculator methods, see Creating and using schedules.

This script demonstrates how to use DurationCalculator to compute a due date.

```javascript
/**
 * Demonstrate the use of DurationCalculator to compute a due date.
 *
 * You must have a start date and a duration. Then you can compute a
 * due date using the constraints of a schedule.
 */

gs.include('DurationCalculator');
executeSample();

/**
 * Function to house the sample script.
 */function executeSample(){

    // First we need a DurationCalculator object.
    var dc = new DurationCalculator();

    // No schedule examples
```
// Simple computation of a due date without using a schedule. Seconds are added to the start date continuously to get to a due date.
dc.setStartDateTime("5/1/2012");
if(!dc.calcDuration(2*24*3600)){
gs.log("**** Error calculating duration");return;
gs.log("calcDuration no schedule: "+ dc.getEndDateTime());
// "2012-05-03 00:00:00" two days later
}

// Start in the middle of the night (2:00 am) and compute a due date 1 hour in the future// Without a schedule this yields 3:00 am.
dc.setStartDateTime("5/3/2012 02:00:00");
if(!dc.calcDuration(3600)){
gs.log("*** Error calculating duration");return;
gs.log("Middle of night + 1 hour (no schedule): "+ dc.getEndDateTime());
// No scheduled start date, just add 1 hour
}

// -------------- Add a schedule to the date calculator ---------------------
addSchedule(dc);

// Start in the middle of the night and compute a due date 1 hour in the future./ Since we start at 2:00 am the computation adds the 1 hour from the start// of the day, 8:00am to get to 9:00am
dc.setStartDateTime("5/3/2012 02:00:00");
if(!dc.calcDuration(3600)){
gs.log("*** Error calculating duration");return;
gs.log("Middle of night + 1 hour (with 8-5 schedule): "+ dc.getEndDateTime());
// 9:00 am
}

// Start in the afternoon and add hours beyond quiting time. Our schedule says the work day// ends at 5:00pm, if the duration extends beyond that, we roll over to the next work day.// In this example we are adding 4 hours to 3:00pm which gives us 10:00 am the next day.
dc.setStartDateTime("5/3/2012 15:00:00");
if(!dc.calcDuration(4*3600)){
gs.log("*** Error calculating duration");return;
gs.log("Afternoon + 4 hour (with 8-5 schedule): "+ dc.getEndDateTime());
// 10:00 am.
}

// This is a demo of adding 2 hours repeatedly and examine the result. This is a good way to visualize the result of a due date calculation.
dc.setStartDateTime("5/3/2012 15:00:00");
for(var i=2; i<24; i+=1)
if(!dc.calcDuration(i*3600)){
    gs.log("*** Error calculating duration");return;
    gs.log("add "+ i +" hours gives due date: "+ dc.getEndDateTime());
}
Simple duration vs relative duration

How much work is required to complete a task can be expressed as a "relative duration".

Relative duration determines the expected due date and time relative to the starting time. Examples of relative durations include "Next business day by 4pm," or "2 business days by 10:30am."

To calculate a relative duration, the calendar and time zone must be considered to determine what "next business day" means since it is the calendar that defines which days are valid work days and the time zone will affect the result as well. As an example, consider "Next business day by 4pm":

- If it is Monday at 12pm: Next business day by 4pm => Tuesday at 4pm
- If it is Friday at 2pm: Next business day by 4pm => the following Monday at 4pm

⚠️ Note: Next business day is often defined by a starting day and time. For example, "next business day at 4pm if before 2pm" indicates that if the current time is after 2pm on a business day, then "Next business day" really means 2 business days since today does not count.
Calculating a simple duration

This business rule and script example demonstrate how to calculate a simple duration.

```javascript
var dur = new DurationCalculator();
dur.setSchedule(current.schedule);
dur.setStartDateTime("");

if(current.duration_type=="""){
    dur.calcDuration(current.duration.getGlideObject().getNumericValue()/1000);}
else{
    dur.calcRelativeDuration(current.duration_type);
}

current.end_date_time= dur.getEndDateTime();
current.work_seconds= dur.getSeconds();
```

This script demonstrates how to use DurationCalculator to calculate a simple duration.

```javascript
/**
 * Sample script demonstrating use of DurationCalculator to compute simple durations
 *
 */

gs.include('DurationCalculator');
executeSample();

/**
 * Function to house the sample script.
 */
function executeSample(){

    // First we need a DurationCalculator object.
    var dc = new DurationCalculator();

    // Compute a simple duration without any schedule. The arguments
    // can also be of type GlideDateTime, such as fields from a GlideRecord.
    var dur = dc.calcScheduleDuration("5/1/2012","5/2/2012");
    gs.log("calcScheduleDuration no schedule: "+ dur);
    // 86400 seconds (24 hours)

    // The above sample is useful in limited cases. We almost always want to
    // use some schedule in a duration computation, let's load a schedule.
    addSchedule(dc);

    // Compute a duration using the schedule. The schedule
```
Calculating a relative duration

An example of a relative duration calculation script.

This script calculates the relative duration for "Next day at 4pm if after 10am":

```javascript
// Next day at 4pm if before 10am
var days = 1;
if (calculator.isAfter(calculator.startDateTime, "10:00:00"))
    days++;
```
This script demonstrates how to use DurationCalculator to calculate a relative duration.

```java
/**
 * Sample use of relative duration calculation.
 *
 */

gs.include('DurationCalculator');
executeSample();

/**
 * Function to house the sample script.
 */
function executeSample(){

    // First we need a DurationCalculator object. We will also use
    // the out-of-box relative duration "2 bus days by 4pm"
    var dc = new DurationCalculator();
    var relDur = "3bf802c20a0a0b52008e2859cd8abcf2";
    // 2 bus days by 4pm if before 10am
    addSchedule(dc);

    // Since our start date is before 10:00am our result is two days from
    // now at 4:00pm.
    dc.setStartDateTime("5/1/2012 09:00:00");
    if(!dc.calcRelativeDuration(relDur)){
        gs.log("*** calcRelativeDuration failed");
            return;
    }
    gs.log("Two days later 4:00pm: " + dc.getEndDateTime());

    // Since our start date is after 10:00am our result is three days from
    // now at 4:00pm.
    dc.setStartDateTime("5/1/2012 11:00:00");
    if(!dc.calcRelativeDuration(relDur)){
        gs.log("*** calcRelativeDuration failed");
            return;
    }
    gs.log("Three days later 4:00pm: " + dc.getEndDateTime());
}

/**
 * Add a specific schedule to the DurationCalculator object.
 */
```
Elapsed time vs work time

Typically, setting a due date requires that you calculate the actual work time required for completion rather than the total time that elapses until the due date.

SLAs, Workflow tasks, and approvals are examples of situations that require the actual work rather than the total time that has elapsed. In this case, only the part of the day when work is performed is considered when determining when the work is to be complete. For example, if a task is due in 10 hours, but the actual time to perform the task is restricted to a business day schedule, the 10 hours of work can only be done at most 8 hours each day. If this work starts at 10am on Monday, it is expected to complete, or be due, on Tuesday at 12pm:

10am-5pm on Monday (6 hours) + 8am-12pm on Tuesday (4 hours)

How to implement a relative duration

You can implement a relative duration by creating the cmn_relative_duration table and the DurationCalculator script include.

Before you begin
Role required: admin

Procedure
1. Create the cmn_relative_duration table.
2. Create the DurationCalculator script include.
3. Create a sample relative duration entry (for example, "Next business day by 4pm").
4. Add the needed fields to SLA tables to support relative durations.
5. Modify duration calculation for SLAs.
6. Modify SLA Percentage timer calculation for SLAs (this must use work_seconds).
7. Add schedule fields to the Workflow: Schedule and Timezone (selected based on the field from workflow table).
8. Add duration support fields to the Workflow Task activity.
9. Implement duration calculation script for the task activity.

The relative duration table and the DurationCalculator methods

The cmn_relative_duration table supports the definition of a due date as either a duration of time or a relative duration.

This table consists of two fields: "name" and "script." The "script" field contains the relative duration calculation script. This script includes the "calculator" variable, which is used to calculate the due date.

The DurationCalculator script include can be used to perform the duration calculations. The following are methods that are available in this script include.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>setSchedule(String schedID, [String timezone])</td>
<td>Sets the schedule and time zone to be used for calculating the due date.</td>
</tr>
<tr>
<td>setStartDateTime(GlideDateTime start)</td>
<td>Sets the start time for the duration calculations. If 'start' is blank, uses current date/time.</td>
</tr>
<tr>
<td>calcDuration(int seconds)</td>
<td>Calculates the end date and time. Upon completion the this.endDateTime and this.seconds properties will be set to indicate the results of the calculation.</td>
</tr>
<tr>
<td>calcRelativeDuration(String relativeDurationID)</td>
<td>Calculates the duration using the specified relative duration script. Upon completion the this.endDateTime and this.seconds properties will be set to indicate the results of the calculation.</td>
</tr>
</tbody>
</table>
## DurationCalculator script include table (continued)

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getEndDateTime()</td>
<td>Gets the this.endDateTime property that was set by calcDuration/calcRelativeDuration indicating the end date and time for the duration.</td>
</tr>
<tr>
<td>getSeconds()</td>
<td>Gets the this.seconds property that was set by calcDuration/calcRelativeDuration indicating the total number of seconds of work to be performed for the duration.</td>
</tr>
<tr>
<td>getTotalSeconds()</td>
<td>Gets the this.totalSeconds property that was set by calcDuration/calcRelativeDuration indicating the total number of seconds between the start and end times of the duration.</td>
</tr>
</tbody>
</table>

**Note:** This is the total work time, not the total time between start and end times and may be used to determine percentages of the work time.

## Relative duration script functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean isAfter(GlideDateTime dt, String time)</td>
<td>Is 'time' of day after the time of day specified by 'dt'? dt, if blank, uses current date/time. time is in &quot;hh:mm:ss&quot; in 24-hour format.</td>
</tr>
<tr>
<td>calcRelativeDueDate(GlideDateTime start, int days, String endTime)</td>
<td>Calculates the due date starting at 'start' and adding 'days' using the schedule and time zone. When we find the day that the work is due on, set the time to 'endTime' of that day. Upon completion, this.endDateTime and this.seconds properties will be set to indicate the results of the calculation.</td>
</tr>
</tbody>
</table>
Relative duration script functions (continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>endTime is blank, use end of the ending work day.</td>
<td></td>
</tr>
</tbody>
</table>

JavaScript engine on the platform

The JavaScript engine that evaluates scripts supports the ECMAScript5 standard and is based on Rhino version 1.7 R5.

There are no plugins or properties needed to install the new JavaScript engine. Starting with the Helsinki release, all instances use the JavaScript engine that supports ECMAScript5.

The benefits include the following.

- You can use modern library code, such as lodash.js and moment.js.
- Your script will follow standard ECMAScript5 behavior.

What you need to know

The JavaScript engine provides an improved environment for developing scripts.

- Legacy code continues to work.
- Compatibility mode supports the legacy modifications to the old JavaScript engine.
- All scripts created prior to the Helsinki release and global scripts run in compatibility mode.
- New applications created in Helsinki and later releases default to run in ES5 standards mode.

For additional information on this topic, see this ServiceNow Community discussion on support for ECMAScript 2015 (ES6) or newer.

JavaScript modes

To support existing scripts and new scripts developed to the ECMAScript5 standard, the JavaScript engine has two modes. The modes are Compatibility Mode and ES5 Standards Mode. The JavaScript engine dynamically determines which mode to use on a script-by-script basis.
**Compatibility mode**

Compatibility mode is used for all scripts developed prior to the Helsinki release, and all global scripts. Compatibility mode has some differences from the old JavaScript engine.

JSON support changes.

- `JSON.stringify()` and `JSON.parse()` are now implemented using the ES5 Native JSON object.
- The new `JSON().encode()` and new `JSON().decode()` are still supported, but should only be used when the legacy behavior is required.

The use of 3rd party JavaScript libraries is not supported in Compatibility mode.

**ES5 Standards mode**

ES5 Standards mode is the default when you create new scoped scripts. This mode does not preserve the legacy behaviors in the pre-Helsinki JavaScript engine.

ES5 standards mode supports ECMAScript5 syntax and features, including the following.

- The `use strict` declaration
- Control over extensibility of objects
- Get and set properties on objects (accessors)
- Control over write-ability, configurability, and enumer-ability of object properties
- New Array and Date methods
- Native JSON support
- Support for modern third-party libraries such as lodash.js and moment.js

**Porting code to ES5 standards mode scripts**

ES5 standards mode catches errors that compatibility mode allows.

Things to watch for when porting code from existing scripts to new scoped scripts using ES5 standards mode.

ECMAScript5 evaluates the term `new Boolean(false)` to true. In compatibility mode, it evaluated to false.

ECMAScript5 throws an EcmaError when a non-existent property is referenced. In compatibility mode no error was thrown.
ECMAScript5 throws an EcmaError when a non-existent function is called. In compatibility mode, no error was thrown.

ECMAScript5 correctly handles new lines. In the past, a newline character after a comment was recognized, which is wrong. In this example, in compatibility mode, all three functions are called. In ECMAScript5, only the first function is called.

```javascript
var expr = doFoo(); // do foo
doBar(); // do bar
finish(); // all done
eval(expr);
```

ECMAScript5 correctly handles postfix increment and decrement. In this example, in compatibility mode, the variable `x` gets the incremented value, which is wrong.

```javascript
var x = gr.limit++;
```

**Debugging scripts**

Debug scripts using session logs and Now Platform debugging tools such as a walk-through script debugger and error messages that display in the UI.

**Debugging server-side scripts**

Use the Script Debugger and session logs to debug server-side code. For more information, see [Script Debugger and Session Log](#).

You can also use session debug to display error messages related to a server-side script that runs as a result of a client-side change. For more information, see [Session debug](#).

**Debugging client-side scripts**

Use session debug to display debugging messages in the user interface. For more information, see [Session debug](#). Use the session log to view logging information for script includes and custom UIs, such as Agent Workspace.

You can also debug client-side scripts using browser-based developers tools.

**Debugging applications and scopes**

Use the application debugging options to understand how a script's application scope might affect your application, table, or record. You may need to update cross-scope privileges to troubleshoot scope access issues. See [Debugging applications](#).
Script Debugger and Session Log

The Script Debugger enables users with the script_debugger role to debug server-side JavaScript, while the Session Log enables you to view and download required logs.

Users with the script_debugger role can perform these actions using Script Debugger:

- Have a dedicated debug transaction, which applies only to the current session.
- Set and remove breakpoints.
- Pause the current session at a breakpoint.
- Evaluate expressions during runtime.
- Step through code line-by-line.
- Step into and out of function and method calls.
- View the value of local and global variables.
- View the value of private variables from function closures.
- View the call stack.
- View the transaction that the system is processing.
- Turn off the script debugger to resume running paused scripts.

Use the Session Log tab to retrieve the session log for business rules, script includes, and a custom UI such as ServiceNow® Agent Workspace that has a GraphQL component. Users with the script_debugger role can:

- View session logs in a separate tab.
- Download a log.
- View logs for Agent Workspace.
- Specify debug options to view or download only the required logs.

By default, 100 transactions and 10,000 messages appear on the Session Log tab. If the transaction or message count exceeds the default value, the session log is cleared and the next transactions or messages appear. You can configure this transaction and message count using the `glide.debugger.log.transaction.count` and `glide.debugger.log_messages_limit` user preferences respectively. For more information about the `glide.debugger.log.transaction.count` and `glide.debugger.log_messages_limit` user preferences, see User preference settings.
Note: Enable Session Log as a separate tab with Script Debugger using the `glide.debugger.log.ui` system property.

- The Page option displays logs under forms and lists and on the Session Log tab.
- The Session option displays logs only on the Session Log tab.

For more information about the `glide.debugger.log.ui` system property, see Available system properties.

When you execute a statement in the Console, the executed statement is stored in the browser cache. You can use the up arrow key to get the previous statement and down arrow key to get the next statement from the browser cache. The user preference setting, `glide.debugger.console.cached_stmt_limit`, defines the number of statements cached in a browser session. The default statement cache value is 20 and the maximum value is 100. You can configure the statement cache value from user preferences.

Note: The cached statements are not available when the browser cache is cleared or when you log in from a different browser or a different computer.

The Script Debugger can pause any server-side script that runs in an interactive transaction such as business rules, script includes, script actions, or UI actions that require a response to proceed. If the GlideSystem method `isInteractive()` returns True when running the script in context, then the Script Debugger can pause it.

Note: Some script objects, such as script includes, can be called from multiple contexts. For example:

- when a business rule runs a script include on a form submit that is an interactive transaction waiting on the form data to change before continuing.
- when a scheduled job runs the same script include that is a non-interactive background transaction that can also run other scripts simultaneously.

To debug client-side scripts, you can use browser-based developers tools. A debugger transaction remains open as long as the user session is valid. If a user logs out or their session times out, the system closes the debugger transaction.

To view debug logs, see Display debugging logs.
Note: When the Script Debugger is enabled, code is executed in interpreted mode. If parts of the script are set to run in strict mode, the debugger is not able to find the correct objects and the debugger fails. The Script Debugger must run on scripts outside of strict mode.

Script Tracer and debugging scripts
The Script Tracer can help you filter your debugging search to quickly narrow down script problems. You can identify lines of scripts in the Glide record that have undergone change during execution. Finding those specific lines of scripts rather than doing a wide search helps save time and improves productivity.

Overview
Use the Script Tracer to narrow your search so you can debug scripts and business rules more efficiently. You can find the Script Tracer by searching in the left navigation pane.

Note: To use the Script Tracer, your role must be admin.

Once you enable Script Tracer and execute a UI transaction, the Tracer searches through all the scripts being executed. The following filters are available:

- **File type**: Search for a specific file type
- **Table**: Look in the specific table for the script being executed

The Script Tracer searches for changes in the script during execution and presents them in a list for you to examine. When you click **Start Tracer**, the Tracer begins searching for changes in the Glide record. You can click the **Debug Script** button at any time to see the script itself.
Use the tabs to see specific information from the Tracer:

- **State**: Displays the difference in the old and new scripts
  - By default, the **Show only changed values** check box is enabled, so you can avoid fields that have not changed.
  - To view all the fields (changed or not), you can clear that check box.

  **Note**: If the file is not reflected in the trace statement, it means the changes in the Glide record is not recognized by the system.
  If there are any errors, they display at the top of the State tab, with their line numbers and error message displayed in order of occurrence.

  **Script**: Displays the line of changed scripts that the Glide record has undergone during execution. You can view the entire line of script by clicking the **Show Script** button.

  **Transaction**: Shows all transaction records of the trace

  **Debug Script**: Opens the script in Debugger to debug the script

  **View File**: Opens the script in the ServiceNow platform for editing

  **Clear trace**: Clears the trace when you are finished.
Limiting the tracer

You may want to set a limit for your trace so that you don't generate too many returns. By default there will be up to 1,000 lines of script traced. Once this number is reached you must clear the trace and start tracing again. If you want to change the maximum number of lines for tracing you can configure your limit using the property `glide.debug.trace.trace_line_limit`.

Since each trace you run is new, make sure you're finished reading the results of one trace before clearing it and beginning another one.

To learn more, see Debugging scripts.

Parts of the user interface

The Script Debugger interface displays information about breakpoints set, the call stack and line number of the currently executing script line, details about variables and transactions, and status of console.
# Parts of the Script Debugger

<table>
<thead>
<tr>
<th>User Interface Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Breakpoints</strong></td>
<td>Displays a list of the breakpoints set by script type, script name, and line number. The debugger updates this list as you add and remove breakpoints.</td>
</tr>
<tr>
<td><strong>Call stack</strong></td>
<td>Displays a list of script calls that preceded or invoked the current line number. This information is only visible when the debugger pauses on a breakpoint.</td>
</tr>
<tr>
<td><strong>Transaction details</strong></td>
<td>Displays information about the current transaction. This information is only visible when the debugger pauses on a breakpoint.</td>
</tr>
<tr>
<td><strong>Status</strong></td>
<td>Displays if the debugger is waiting for a breakpoint, paused on a breakpoint, or has encountered an exception.</td>
</tr>
<tr>
<td>User interface element</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>User</td>
<td>Displays the name of the user who is running the current debugger session.</td>
</tr>
<tr>
<td>Coding pane header</td>
<td>Displays the script type and name of the script in the coding pane.</td>
</tr>
<tr>
<td>Breakpoint icon</td>
<td>Indicates the line number where the debugger pauses when evaluating the current script.</td>
</tr>
<tr>
<td>Pause debugging button</td>
<td>Stops any current debugging session, and disables the Script Debugger for the current user. The Script Debugger doesn't pause on breakpoints for the current user until it's restarted.</td>
</tr>
<tr>
<td>Console</td>
<td>Displays a command line interface used for evaluating expressions during runtime. The console is available only when the script execution is paused.</td>
</tr>
<tr>
<td>Resume script execution button</td>
<td>Advances from the current breakpoint to the next breakpoint. If there are no other breakpoints, the script runs to completion.</td>
</tr>
<tr>
<td>Step over next function call button</td>
<td>Advances past the method that's about to be called, executing the method as a single step.</td>
</tr>
<tr>
<td>Step into next function call</td>
<td>Advances to the first line of executed code within a method call. Stepping into a method updates the current position within the call stack. If the user doesn't have read access to the method call, then this control acts like step over instead.</td>
</tr>
<tr>
<td>Step out of current function</td>
<td>Exits from current method call and returns to the calling script from the call stack. If the user isn’t within a method call, then this control acts like step over instead.</td>
</tr>
</tbody>
</table>
### Parts of the Script Debugger (continued)

<table>
<thead>
<tr>
<th>User Interface Element</th>

<td>Download the logs in HTML file format.</td>
</tr>
<tr>
<td>Settings</td>
<td>Session debug options. For information about the debug options, see Session debug.</td>
</tr>
</tbody>
</table>

Script Debugger step-through and console controls

After the Script Debugger pauses a script, use the step-through controls to move between script lines and move between scripts in the call stack. Use the Console controls to expand console, collapse console, clear console, and rerun expressions.

Step-through controls

<table>
<thead>
<tr>
<th>Control</th>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stop debugging</td>
<td></td>
<td>Stops any current debugging session, and disables the Script Debugger for the current user. The Script Debugger does not pause on breakpoints for the current user until it is restarted.</td>
</tr>
<tr>
<td>SHIFT+F2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Step-through controls (continued)

<table>
<thead>
<tr>
<th>Control</th>
<th>Icon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start debugger - F2</td>
<td>✪</td>
<td>Enables the Script Debugger for the current user. The Script Debugger pauses on breakpoints.</td>
</tr>
<tr>
<td>Resume script execution - F9</td>
<td>▶</td>
<td>Advances from the current breakpoint to the next breakpoint. If there are no other breakpoints, the script runs to completion.</td>
</tr>
<tr>
<td>Step over next function call - OPTION+F9</td>
<td>♻</td>
<td>Advances to the next evaluated line of script based on current conditions. The Script Debugger skips any lines of code that do not need to run because their conditions are not met. For example, when the condition of an <code>if</code> statement is not true, the debugger skips the code block for the condition.</td>
</tr>
<tr>
<td>Step into next function call - OPTION+F10</td>
<td>↓</td>
<td>When the Script Debugger pauses on a method call, this control allows the user to advance to the first line of executed code within the method call. Stepping into a method updates the current position within the call stack. If the user does not have read access to the method call, then this control acts like step over instead.</td>
</tr>
<tr>
<td>Step out of current function - OPTION+F11</td>
<td>↑</td>
<td>When the Script Debugger pauses within a method call, this control allows the user to exit the current method call and return to the calling script from the call stack. If the user is not within a method call, then this control acts like step over instead.</td>
</tr>
</tbody>
</table>

### Console controls

<table>
<thead>
<tr>

</table>

Related information

Set or remove breakpoints

Evaluate expressions in runtime using Console

Define, declare, and verify new variables and functions while you debug a script in runtime using Console. The script execution must be paused in order to use Console.

Before you begin

- Review Limitations with using Console
- Role required: script_debugger, admin

Procedure

1. Launch Script Debugger in one of the following ways:

<table>
<thead>
<tr>
<th>Application</th>
<th>Navigation path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application navigator</td>
<td>Navigate to System Diagnostics &gt; Script Debugger.</td>
</tr>
<tr>
<td>Studio</td>
<td>Navigate to File &gt; Launch Script Debugger.</td>
</tr>
<tr>
<td>Syntax Editor</td>
<td>Click the Script Debugger icon 🔄.</td>
</tr>
</tbody>
</table>

The Script Debugger modal is displayed.

2. Trigger the script.
   For example, create a record to trigger an insert business rule script.
   The Script Debugger pauses the script on the first line that contains a breakpoint, and then you see the ServiceNow Script Debugger confirmation window.
3. Click **Start Debugging**. The focus shifts to the Script Debugger window and you see the target script that paused at the first breakpoint.

> **Note:** Make sure that the status of Script Debugger is **EXECUTION_PAUSED**. You can use Console only when the script execution is paused during debugging.

4. Click the **Open Console** icon to expand the Console pane. To start evaluating expressions, enter one or more expressions in the Console and press Enter. For example, enter `var x = 10;` and press Enter. To enter multiple lines of expressions, press Shift + Enter after each line and press Enter after the last expression. To clear all the expressions in the Console, click the clear console icon.

For more information on Console controls, see **Script Debugger step-through and console controls**.

<table>
<thead>
<tr>
<th>Expressions in the Console</th>
<th>Output in the Console</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>var x = 10;</code></td>
<td><code>x = 10</code></td>
</tr>
<tr>
<td><code>console.log(x);</code></td>
<td><code>10</code></td>
</tr>
<tr>
<td><code>var y = x + 5;</code></td>
<td><code>y = 15</code></td>
</tr>
<tr>
<td><code>console.log(y);</code></td>
<td><code>15</code></td>
</tr>
<tr>
<td><code>var z = y * 2;</code></td>
<td><code>z = 30</code></td>
</tr>
<tr>
<td><code>console.log(z);</code></td>
<td><code>30</code></td>
</tr>
</tbody>
</table>
After a statement is executed, it is stored in the browser cache. You can use the up arrow key to get the previous statement and down arrow key to get the next statement from the browser cache. You can configure the number of cached statements for a session from user preferences. For more information about user preferences settings, see Script Debugger and Session Log.

Limitations with using Console

Limitations with using Console
You need to be aware of a few limitations when you use Console to evaluate expressions while debugging a script in runtime.

• The properties and values of an object don’t display in Console. When you try to display an object to Console, only the string value of the object appears.
• Console doesn’t support GlideSystem printing methods, such as info() and print().
• You can’t use the `this` keyword in Console.
• A script debugger timeout occurs when you evaluate expressions in Console.
• While executing long scripts, if you see the response Awaiting response from server, you can’t resume debugging or stop debugging using the resume or stop controls.

Launch the Script Debugger
Developers can launch the Script Debugger from the application navigator, Studio, or from the syntax editor.

Before you begin
Role required:
• admin
• script_debugger

Procedure
Select a path based on your starting point:

<table>
<thead>
<tr>
<th>Starting point</th>
<th>Navigation path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application navigator</td>
<td>Navigate to System Diagnostics &gt; Script Debugger.</td>
</tr>
</tbody>
</table>
The system opens the Script Debugger in a new window.

### Set or remove breakpoints

Set breakpoints or conditional breakpoints to pause scripts at specific lines, and remove breakpoints when you are done debugging them.

**Before you begin**

Role required:

- admin
- script_debugger

**About this task**

Breakpoints belong to the developer who sets them. Developers must set and remove their own breakpoints.

❓ **Note:** At a specific line, you can set either a logpoint or breakpoint but not both.

**Procedure**

1. Navigate to the server script to debug. For example, navigate to **System Definition** > **Business Rules**.

2. From the Syntax Editor, click the gutter next to a script line.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Set a breakpoint</strong></td>
<td>Click a blank line to set a breakpoint.</td>
</tr>
<tr>
<td><strong>Set a conditional breakpoint</strong></td>
<td>Right-click a blank line and click <strong>Add conditional breakpoint</strong> to set a conditional breakpoint.</td>
</tr>
<tr>
<td><strong>Remove a breakpoint</strong></td>
<td>Click a breakpoint to remove it.</td>
</tr>
<tr>
<td><strong>Remove a conditional breakpoint</strong></td>
<td>Right-click a conditional breakpoint and select <strong>Remove breakpoint</strong> to remove it.</td>
</tr>
</tbody>
</table>
3. From the Syntax Editor toolbar, click the **Open Script Debugger** icon. The system opens a Script Debugger window.

4. Trigger the script. For example, create a record to trigger an insert business rule script. The Script Debugger pauses the script on the first line containing a breakpoint, and the system displays a confirmation window.

5. Click **Start Debugging**. The system switches focus to the Script Debugger window and displays the target script paused at the first breakpoint. Console pane is enabled.

6. When debugging is complete, remove breakpoints from the script.

**Related reference**

- **Script Debugger step-through and console controls**
- **Set or remove logpoints**

Set breakpoints or conditional logpoints to log messages to the console at specific lines, and remove logpoints when you are done debugging them.

**Before you begin**

- Set the `glide.debug.log_point` system property to `true`. See Available system properties for more information.
- Role required: admin or script_debugger

**About this task**

Logpoints belong to the developer who sets them. Developers must set and remove their own logpoints.

**Note:** At a specific line, you can set either a logpoint or breakpoint but not both.
Procedure

1. Navigate to the server script to debug. For example, navigate to System Definition > Business Rules.
2. From the Syntax Editor, click the gutter next to a script line.

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set a logpoint</td>
<td>Right-click a blank line and click Add logpoint to set a logpoint.</td>
</tr>
<tr>
<td>Remove a logpoint</td>
<td>Right-click a logpoint and select Remove logpoint to remove it.</td>
</tr>
<tr>
<td>Edit a logpoint</td>
<td>Right-click a logpoint and select Edit logpoint to edit it.</td>
</tr>
</tbody>
</table>

ℹ️ Note: The script entered for the logpoint must have the same format as that of the script in GSLog and GSInfo script includes.

3. From the Syntax Editor toolbar, click the Open Script Debugger icon 🚀.
4. On the Script Debugger window, trigger the script. For example, create a record to trigger an insert business rule script.

ℹ️ Note: You can also add logpoints in the Script Debugger window.
5. In the Script Debugger window, click Session Log to view the logpoints.
6. When debugging is complete, remove logpoints from the script.

Script Debugger status

The Script Debugger status determines what debugging actions are available and what information it can display.

The Script Debugger displays its status at the bottom left of the user interface.

Sample Script Debugger status

ℹ️ Status: EXECUTION_PAUSED
<table>
<thead>
<tr>
<th>Status</th>
<th>Occurs when</th>
<th>Description</th>
<th>Actions available</th>
</tr>
</thead>
<tbody>
<tr>
<td>WAITING FOR FIRST BREAKPOINT</td>
<td>- The user opens a Script Debugger window or tab.</td>
<td>The Script Debugger is ready to pause script and display debugging information.</td>
<td>- Pause script at the first breakpoint in the call stack.</td>
</tr>
<tr>
<td>EXECUTION_PAUSED</td>
<td>- The Script Debugger pauses on a breakpoint.</td>
<td>The Script Debugger has paused on a line of code, and the user can debug the script. Console is enabled.</td>
<td>- Resume processing until the Script Debugger reaches the next breakpoint.</td>
</tr>
<tr>
<td></td>
<td>- The user steps over, steps into, or steps out to the next line of evaluated code.</td>
<td></td>
<td>- Step through a script.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Display the call stack.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Display transaction information.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Display variable values.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Evaluate expressions in Console during runtime.</td>
</tr>
<tr>
<td>WAITING FOR BREAKPOINT</td>
<td>- The user resumes processing until the Script Debugger reaches the next breakpoint.</td>
<td>The Script Debugger is searching for the next line of code at which to pause. Users will typically never see this status because the Script Debugger changes status.</td>
<td>- Pause script at the next breakpoint.</td>
</tr>
<tr>
<td></td>
<td>- The user steps through a script until the Script Debugger</td>
<td></td>
<td>- Pause script at the next script line requiring evaluation.</td>
</tr>
</tbody>
</table>
Possible Script Debugger status values (continued)

<table>
<thead>
<tr>
<th>Status</th>
<th>Occurs when</th>
<th>Description</th>
<th>Actions available</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>reaches the next line of code to evaluate or the transaction completes.</td>
<td>after it locates the next breakpoint or script line to evaluate.</td>
<td></td>
</tr>
</tbody>
</table>
| OFF    | • The user pauses the Script Debugger.  
        • The user closes the Script Debugger window or tab.  
        • The user session ends for any reason.  
        • The administrator resets all Script Debugger instances by navigating to the debugger_reset.do page. | The Script Debugger is inactive and does not pause scripts or display debugging information. | • Start the Script Debugger.  
        • Open a Script Debugger window or tab. |

Log entries
Every time a debug transaction finishes executing, the system creates a log entry for it with a DEBUGGED prefix. For example:

```
2016-08-15 15:57:32 (197) Default-thread-3 900F510167112200C4098C7942415A75 *** End  
#39, path: /my-app.do, user: admin, DEBUGGED total transaction time: 0:00:11.010,  
transaction processing time: 0:00:11.010, network: 0:00:00.000, chars: 6,058, uncompressed  
chars: 20,731, SQL time: 50 (count: 34), business rule: 0 (count: 0), phase 1  
form length 56,464, largest chunk written: 10,428, request parms size: 40, largest input  
read: 0
```
Transaction details

The Script Debugger displays transaction details for the current paused user session.

Transaction details are available in a dedicated resizeable section underneath the Call Stack on the bottom left of the Script Debugger.

The Script Debugger only displays transaction details when it pauses on a script. Developers can use transaction details to:

- Inspect the URL of the currently paused transaction.
- Inspect the request parameters for the currently paused transaction.
- Inspect network information about the current transaction.
- Inspect the user and session ID that initiated the debug transaction.

Related reference

Available transaction details

The Script Debugger provides a standard set of transaction details for developers to debug and troubleshoot scripts.
### Available transaction details

<table>
<thead>
<tr>
<th>Transaction element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>url</td>
<td>The URL of the currently paused transaction.</td>
</tr>
<tr>
<td>Request parameters</td>
<td>The list of request parameters for this transaction. Each transaction has its own list of request parameters, but record transactions typically include the field values used to insert, update, or delete a record.</td>
</tr>
<tr>
<td>instance</td>
<td>The instance name.</td>
</tr>
<tr>
<td>address</td>
<td>The IP address of the end-user client system.</td>
</tr>
<tr>
<td>session</td>
<td>The user session ID.</td>
</tr>
<tr>
<td>forward</td>
<td>The IP address of the load balancer.</td>
</tr>
<tr>
<td>query count</td>
<td>The number of database queries the Script Debugger has made.</td>
</tr>
<tr>
<td>thread</td>
<td>The name of the thread running the Script Debugger instance.</td>
</tr>
<tr>
<td>transactionid</td>
<td>The Sys ID of the current transaction.</td>
</tr>
<tr>
<td>token</td>
<td>The Script Debugger token of the currently paused transaction. The system uses this token to identify different Script Debugger instances.</td>
</tr>
<tr>
<td>name</td>
<td>The name of the currently paused transaction. You can use this name to identify transactions in the logs.</td>
</tr>
<tr>
<td>processor</td>
<td>The name of the processor processing the current transaction, if present.</td>
</tr>
<tr>
<td>method</td>
<td>The HTTP request method the currently paused transaction uses.</td>
</tr>
<tr>
<td>startTime</td>
<td>The date-time stamp when the Script Debugger instance started.</td>
</tr>
<tr>
<td>page</td>
<td>The current table or UI page associated with the transaction.</td>
</tr>
<tr>
<td>user</td>
<td>The user who triggered the debug transaction.</td>
</tr>
<tr>
<td>nodeid</td>
<td>The Sys ID of the node running the Script Debugger instance.</td>
</tr>
</tbody>
</table>

### Related information

**Transaction details**
Script Debugger multiple developer support

The Script Debugger allows multiple developers to debug their own transactions without affecting each other.

The Script Debugger only allows developers to see and interact with items related to their current debugging session such as:

- Breakpoints
- Call stack
- Console
- Transactions
- Status

The Script Debugger prevents one developer from seeing or modifying another debug session. Administrators, however, can impersonate another user, open the Script Debugger, and debug transactions generated by the impersonated user.

The Script Debugger displays the debug session user at the bottom left of the user interface.

Sample Script Debugger user

User: System Administrator

Concurrent Script Debugger usage

By default, the system supports debugging \[ (\text{The number of semaphores on the instance}) / 4 \] concurrent transactions. Administrators can specify the number of concurrent transactions the system can debug by setting the `glide.debugger.config.max_node_concurrency` system property. The system can debug up to \[ (\text{The number of semaphores on the instance}) - 2 \] concurrent transactions.

Administration of debugging sessions

Debugging sessions can remain actively debugging (in the EXECUTION_PAUSED or WAITING_FOR_BREAKPOINT statuses) until:

- The user pauses the Script Debugger.
- The user closes the Script Debugger.
- The user session ends.

Administrators can view the currently running debugger sessions by navigating to the page `xmlstats.do`. 
Administrators can stop all currently running debugging sessions by navigating to the page `debugger_reset.do`. Only users with the admin role can access this page.

**Related information**

**Script Debugger impersonation support**

You can use the Script Debugger while impersonating another user, but only if the impersonated user has the script_debugger role and has read access to the target script.

While impersonating another user, you can:

- See and change breakpoints that belong to the impersonated user.
- View and pause on scripts that the impersonated user has read access to.
- Evaluate expressions in Console on behalf of the impersonated user.

The Script Debugger step-through controls also use the read access of the impersonated user. For example, if the impersonated user does not have read access to a function in the call stack, any **Step into** action instead becomes a **Step over** action.

The impersonated debugging session lasts until:

- You stop impersonating the user.
- You log out or the user session ends.
- You pause the Script Debugger.
- You close the Script Debugger.

**Related information**

**Script Debugger multiple developer support**

**Script Debugger Scripts - Background support**

The Scripts - Background module does not support setting breakpoints directly in the script field. You can however, set breakpoints in the script objects called or triggered by the Scripts - Background module.

While running arbitrary JavaScript code in the **Scripts - Background** module, the Script Debugger can only pause scripts when you:
• Call a script include containing breakpoints.
• Trigger a business rule containing breakpoints.
• Trigger a script action containing breakpoints.

Domain separation and Script Debugger

Domain separation is supported in Script Debugger. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Support level: Basic

• Business logic: Ensure that data goes into the proper domain for the application’s service provider use cases.
• The application supports domain separation at run time. The domain separation includes separation from the user interface, cache keys, reporting, rollups, and aggregations.
• The owner of the instance must set up the application to function across multiple tenants.

Sample use case: When a service provider (SP) uses chat to respond to a tenant-customer’s message, the client must be able to see the SP’s response.

For more information on support levels, see Application support for domain separation.

How domain separation works in Script Debugger

Script Debugger is not a full application but rather, a feature in the Platform suite, meaning it works alongside other features, including domain separation.

Related information

Domain separation for service providers

Session debug

Enable session debugging to display debugging messages in the user interface.

You can enable all areas for abundant logging on the bottom of each page load, or you can enable each module one by one, for more specific information about what is happening during this session, and specifically, for the previous transaction. Select session debug options under System Diagnostics > Session
Debug. When enabled, session debugging is active during the user session or until disabled. To view debug logs, see Display debugging logs.

The system provides the following session debugging options.

<table>
<thead>
<tr>
<th>Debug option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable All</td>
<td>Displays all available debugging messages.</td>
</tr>
<tr>
<td>Disable All</td>
<td>Stops displaying all debugging messages.</td>
</tr>
<tr>
<td>Debug Business Rule</td>
<td>Displays debugging messages for business rules. If there are business rules from multiple applications affecting a table or record, the system displays which application the business rule comes from.</td>
</tr>
<tr>
<td>Debug Upgrade</td>
<td>Displays detailed information logged for records processed during the last family-to-family or patch version upgrade session. See Debug Upgrade.</td>
</tr>
<tr>
<td>Debug Business Rule (Details)</td>
<td>Displays debugging messages for business rules and any changes made by business rules. If there are business rules from multiple applications affecting a table or record, the system displays which application the business rule comes from.</td>
</tr>
<tr>
<td>Debug Log</td>
<td>Displays all log entries.</td>
</tr>
<tr>
<td>Debug Date/Time</td>
<td>Displays Date/Time failures when inputs do not match required formats.</td>
</tr>
<tr>
<td>Debug SQL</td>
<td>Displays debugging messages for SQL queries.</td>
</tr>
<tr>
<td>Debug SQL (Detailed)</td>
<td>Displays debugging messages for SQL statements and any changes made by SQL statements.</td>
</tr>
<tr>
<td>Debug Security</td>
<td>Displays debugging messages for access controls. If there are access controls from multiple applications affecting a table or record, the system displays which application the access controls comes from.</td>
</tr>
<tr>
<td>Debug Escalations</td>
<td>Displays debugging messages for SLA and SLO escalations.</td>
</tr>
<tr>
<td>Debug AI Search</td>
<td>Displays debugging messages for AI Search.</td>
</tr>
</tbody>
</table>
### Session debug options (continued)

<table>
<thead>
<tr>
<th>Debug option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debug Metric Statistics</td>
<td>Displays an aggregate view of performance data (slow transactions, scripts, queries, events, and mutexes). These aggregate metrics are sorted by transaction, to help identify items that affect page performance.</td>
</tr>
<tr>
<td>Debug Text Search</td>
<td>Displays debugging messages for search result relevance and indexing.</td>
</tr>
<tr>
<td>Debug UI Policies</td>
<td>Displays debugging messages for UI policies.</td>
</tr>
<tr>
<td>Disable UI Policies Debug</td>
<td>Stops displaying debugging messages for UI policies.</td>
</tr>
<tr>
<td>Debug UI Macro</td>
<td>Displays the start and end of the UI Macro in the DOM as HTML comments. The comments consist of table name and UI macro name.</td>
</tr>
<tr>
<td>Disable Debug UI Macro</td>
<td>Stops displaying the start and end of the UI Macro in the DOM as HTML comments.</td>
</tr>
<tr>
<td>Debug Data Policies</td>
<td>Displays debugging messages for data policies.</td>
</tr>
<tr>
<td>Debug Quotas</td>
<td>Displays debugging messages for transaction quotas.</td>
</tr>
<tr>
<td>Debug Homepage Render</td>
<td>Displays debugging messages for homepages.</td>
</tr>
<tr>
<td>Debug Scopes</td>
<td>Displays debugging messages for entering or exiting application scopes when running script objects.</td>
</tr>
</tbody>
</table>

### Display debugging logs

Display session debug logs to help diagnose script and application problems.

**Before you begin**

Role required: none
Procedure

1. Navigate to System Diagnostics > Script Debugger > Session Debug and click Enable All.
2. Under Session Debug, click Debug Log. The Debug log displays.

Debugging applications

Application developers can display debug messages about configuration records to help them troubleshoot issues. The Debug Scopes module provides information about the system switching between custom applications to run server-side scripts.

The system offers the following debugging options to help application developers determine how applications affect configuration records.

<table>
<thead>
<tr>
<th>Application debug options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debugging option</td>
</tr>
<tr>
<td>-------------------</td>
</tr>
<tr>
<td>Debug Business Rule</td>
</tr>
<tr>
<td>Debug Business Rule (Details)</td>
</tr>
<tr>
<td>Debug Security</td>
</tr>
<tr>
<td>Debug Scopes</td>
</tr>
<tr>
<td>Enable Session Debug</td>
</tr>
</tbody>
</table>

When multiple applications contribute to the debug output, the system adds a new section called Apps to the display a list of the applications writing to the
session log. Clicking on the check box next to the application name hides or displays the application’s associated debug messages.

**Sample application debug output of business rules**

Debugging scopes

Application developers can use the **Debug Scopes** module to display information about when the system switches between custom applications to run server-side scripts.

When enabled, the system displays a message whenever the system switches to a custom application to run a server-side script.

**Sample debug scopes output from the incident table**

Every time the system runs a server-side script object it enters the script's scope context. When the script finishes running, the script exits the scope context. The debugging messages track changes to the script scope context.

The debugging message displays a greater than character > each time the system enters a script object's context, and displays a less than character < every time the system exits a script object's context. In cases where one script calls another the debugging message adds another greater than character to the path for each call. For example, if a business rule calls a script include, which in turn calls another script object there would three characters in the path such as:
> Entering scope [x_app_one]
>> Entering scope [x_app_two]
>> Entering scope [x_app_three]

> Note: The system does not display entering or exiting messages for script objects in the global scope.

Application developers may want to enable other debugging options to in conjunction with this option to see information about the possible source of the server-side script such as Debug Business Rule.

**Debugging business rules**

Debugging business rules can be achieved with resources available in the ServiceNow product.

**1. Tools**

The first step in the process is to identify tools which will help you figure out what's wrong.

### Debugging tools

<table>
<thead>
<tr>
<th>Debugging tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Dictionary</td>
<td>Navigate to System Definition &gt; Dictionary. The dictionary provides a list of all tables within your instance and can be invaluable when trying to locate information.</td>
</tr>
<tr>
<td>System Log</td>
<td>Navigate to System Logs &gt; System Log. You can place alert statements in your business rule which can write information to the log.</td>
</tr>
<tr>
<td>Debug Business Rule (Details)</td>
<td>Navigate to System Diagnostics &gt; Session Debug &gt; Debug Business Rule (Details). This debugging module displays the results business rules. Use this module to see if conditions are being met and values are being set as expected.</td>
</tr>
<tr>
<td>Alert Messages</td>
<td>There are several system functions that allow you to print messages to the page, the field or the log file. See Scripting alert, info, and error messages.</td>
</tr>
<tr>
<td>Business Rule Examples</td>
<td>Sometimes you can find what you're looking for in scripts others have written, including business rule error messages, or by building an OR query.</td>
</tr>
</tbody>
</table>
Debugging tools (continued)

<table>
<thead>
<tr>
<th>Debugging tool</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlideRecord Information</td>
<td>This is the basic syntax used to query the database for information. See Querying tables in script. GlideRecord also includes aggregation support.</td>
</tr>
</tbody>
</table>

2. Variables

The next step is to gain some insight into the behavior of your business rule. For every action except an insert, you will more than likely use a query to get your record(s).

```javascript
var rec = new GlideRecord('incident');
rec.addQuery('active',true);
rec.query();
while (rec.next()) {
  gs.print(rec.number + ' exists');
}
```

To verify whether your query is actually returning records you can use `gs.addInfoMessage` to display information at the top of the screen.

```javascript
var rec = new GlideRecord('incident');
rec.addQuery('active',true);
rec.query();
gs.addInfoMessage("This is rec.next: " + rec.next());
while (rec.next()) {
  gs.print(rec.number + ' exists');
}
```

If your query returns no records you see the following:

This is rec.next: false

Use this technique to verify every variable within your business rule contains expected values.

⚠️ Tip: If necessary, break your script down into individual pieces and verify each piece works separate from the whole and then put them all back together one step at a time.

3. Locating information

The last step is to make sure you know where to find the information your rule is looking for.
In the ServiceNow application, one table can extend another table. This means when searching for information, you might need to query the parent table for the extended table’s sys_id to find what you seek.

A good example is the sc_task table, which extends the task table. The script below queries the extended table (sc_task) for the current sys_id and then query the parent table (task) for records with the matching sys_id, and then prints out the work notes field.

```javascript
var kids = new GlideRecord('sc_task');
kids.query();
go.addInfoMessage("This is requested item number: " + current.number);
go.print("This is the requested item number: " + current.number);

while (kids.next()) {
    var parents = new GlideRecord('task');
    parents.addQuery('sys_id', '=', kids.sys_id);
    parents.query();

    while(parents.next()) {
        go.addInfoMessage("This is task number: " + parents.number);
        go.print("This is task number: " + parents.number);
        go.addInfoMessage("These are the work notes: " + parents.work_notes);
        go.print("These are the work notes: " + parents.work_notes);
    }
}
```

**Debugging classifications**

You must add a system property to enable classification debugging.

**Debugging classifications**

The resulting log entries list the name of each classifier that runs, along with all the names and values that are available to the criteria in the classifier. To log debugging information about classifications, add the following system property.

<table>
<thead>
<tr>
<th>System Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>glide.discovery.debug.ci_identification</td>
<td>Enables debugging information for process classification.</td>
</tr>
</tbody>
</table>
### Field watcher

The field watcher tool tracks and displays all actions that the system performs on a selected form field.

Administrators can use the field watcher to figure out what happens to the field and how the value of the field changes when an event such as the firing of a business rule or enforcement of a data policy, takes place. Administrators can also impersonate non-admin users to debug what happens when those users make changes on an instance. Only one field can be watched at a time. Non-admin users with the impersonator role have access to the field watcher feature.

### How the field watcher works

The Field Watcher tool logs activity when any of the following events occur on a field:

- The default value is set on the field.
- User access rights for the field change due to an ACL or dictionary setting.
- A data policy prevents the value from being set.
- A reference qualifier query of the field value executes.
- A UI policy changes a field to or from read-only, visible, mandatory, or editable.
- A dependent value in another field restricts field choices.
- The value of the field is set or changed based on:
  - Assignment rules
  - Actions from an engine, such as the workflow engine
  - Business rules
  - User entries
  - Client scripts
  - UI actions
Note: The field watcher works only on form fields. It cannot be used on list fields. Also, field watcher is not available on password-protected fields or encrypted fields. Field watcher is only available within the UI frame. The option to watch a field does not appear in the context menu if you open a record outside of the UI frame, for example, in a new tab.

Use field watcher

Access field-level debugging information using the field watcher.

Procedure

1. Navigate to the form for which you want to view field-level debugging information.

2. Activate field watcher by right-clicking any field label on a form and select Watch - '<field name>'.

   The debug icon (工期) appears next to the field label. From this point on, the field watcher records every action taken on the selected field. For example, if you are watching a Priority field, if the priority is changed from Moderate to Low and the record is updated, the field watcher will display information about that change.

3. View the field watcher log by clicking the debug icon.
   A new pane opens at the bottom of the screen, showing a field watcher tab. It may also show tabs for JavaScript Logging and JavaScript Debugger.

4. Click the Field Watcher tab, if needed.

5. Stop watching a field by right-clicking the field and selecting Unwatch - '<field name>'. To watch another field, right-click that field and select Watch - '<field name>'.
6. Clear the field watcher log by clicking the clear log button ( ).

7. Resize the field watcher pane by dragging the splitter bar up or down. Dragging the splitter bar to the bottom of the screen closes the field watcher pane. Reopen the pane by clicking the debug icon again.

Field watcher tab details

The field watcher displays field information and configuration options. The left-side of the Field Watcher tab shows the following information for the watched field.

- **Table**: table to which the field belongs.
- **Element**: field label.
- **Type**: type of data stored in the field.
- **Dependent**: field on which the current field depends.
- **Reference**: table from which the field’s value originates, if applicable.
- **Reference Qual**: reference qualifiers that may be restricting data on the field.
- **Attributes**: attributes on the field as specified in the dictionary entry for that field.

On the right-side of the Field Watcher tab, select the types of activity information you want to see for the selected field. Clear the check box for any type of information that is not needed.

Watching a hidden field

Administrators may need to watch a hidden field.

Procedure

1. Use the dictionary to determine the column name of the field.
2. Elevate privileges to the security_admin role.
3. Navigate to **System Definition > Scripts Background**.
4. In **Run script (JavaScript executed on server)**, enter the following command:

   ```javascript
gs.getSession (). setWatchField ( "hidden_field" ) ;
   ```

   Replace hidden_field with the column name of the hidden field.
5. Navigate to the form containing the missing field.

   The Field Watcher tab output contains information about the hidden field.
Viewing information for the watched field

When information for a watched field is changed and the record is updated, the field watcher tab displays relevant information at the bottom.

Field watcher viewing data

Field watcher information includes:

- **Timestamp**: time the field was changed using the HH:MM:SS (ms) format.
  - Orange text: server-side changes, such as ACLs.
  - Blue text: client-side changes, such as client scripts.

- **Type of object that changed the field and its associated name**: The type of item that changed on the field; for example, **CLIENT SCRIPT**, **BUSINESS RULE**, or **ACL**. In the case of scripts, business rules, or other configuration-type fields, field watcher displays the name of the script or business rule that changed the field, if any. Click the name to go directly to the record for that item.

- **Old and new values**: The old and new values for the field, if the value changed. Field watcher does not record the value if it was inserted in the form by default at the time the record was created.

- **Additional information**: Call tracing information, such as the name of the script engine or workflow that changed the field. Click the plus icon to expand the selection.
  - Orange text: Indicates server-side activity.
  - Blue text: Indicates client-side activity.

**Example: Watching the incident priority**

The following example shows what happens to the **Priority** field on the incident form when both the **Impact** and **Urgency** fields change.

The Incident form has two client-side data lookups change the priority. Additionally, server-side ACLs and the data lookup engine fire when the record...
is saved. Finally, a client-side UI policy sets the **Priority** field back to read-only, which is the default setting.

### Watching the incident priority

<table>
<thead>
<tr>
<th>Original values</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Priority:1 - Critical</td>
</tr>
<tr>
<td>• Impact:1 - High</td>
</tr>
<tr>
<td>• Urgency:1 - High</td>
</tr>
</tbody>
</table>

#### First Change

1. The user changes the **Impact** value to **3 - Low**.
2. The priority automatically changes to **3 - Moderate** based on the **Priority Lookup** data lookup definition used by default in ServiceNow incidents.

**Note:** At this point, the record has not been saved.

#### Second Change

1. The user changes the **Urgency** value to **2 - Medium**.
2. The priority automatically changes to **4 - Low** based on the same **Priority Lookup** data lookup definition.
3. The user saves the record by right-clicking the form header and choosing **Save**.

#### Field watcher example

<table>
<thead>
<tr>
<th>Table: Incident Type</th>
<th>Element: Priority</th>
<th>Reference: Priority Qualifiers</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>integer</td>
<td></td>
</tr>
</tbody>
</table>

First Change:

- **1:** 14:26:26 (602)  
  DATA_LOOKUP - change of incident impact
  1 → 3

- **2:** 14:26:26 (458)  
  DATA_LOOKUP - change of incident urgency
  3 → 4

Second Change:

- **1:** 13:38:38 (290)  
  UI ACTION: **Save**

- **2:** 13:38:38 (600)  
  ACL - recordincident.priority/write
  true

- **3:** 13:38:38 (600)  
  ACL - recordincident.priority/create
  true

**Note:** The values that change from 1 to 3, and then from 3 to 4, refer to the numerical values in the choice list.
**Writing to the debug log**

To write to the debug log in your client-side JavaScript, or UI policies, make a call to the global function `jslog()`.

An example of using `jslog()` in JavaScript:

```javascript
function logData (r ) {
    lastLogDate  = r. responseXML. documentElement. getAttribute ( "last_log_entry" ) ;
    var items  = r. responseXML. getElementsByTagName ( "log" ) ;
    jslog ( "response=" + r. responseText ) ;
}
```

Additionally, when client scripts run, the name of the client script and timing information is displayed. This can be useful in determining which scripts are running and whether they are impacting performance.

**Debug UI policies**

Enabling the `glide.ui.ui_policy_debug` property lets you monitor the processing of UI actions.

Here are some sample log events from an incident policy that sets fields to read-only if the incident_state is closed.

```
GlideFieldPolicy: Evaluating condition
GlideFieldPolicy:     incident_state (7) = 7 -> true
GlideFieldPolicy: -->>> TRUE
GlideFieldPolicy: Setting opened_at disabled to true
GlideFieldPolicy: Setting opened_by disabled to true
GlideFieldPolicy: Setting closed_at disabled to true
GlideFieldPolicy: Setting closed_by disabled to true
GlideFieldPolicy: Setting company disabled to true
```

**Access the JavaScript log**

JavaScript that runs on the browser, such as client scripts, can include a call to `jslog()` to send information to the JavaScript Log. Users with the admin role can access this log.
Procedure

1. Open the JavaScript log by navigating to the appropriate location for your version of the UI.

| UI16                | a. Click the gear icon in the banner frame.  
|                    | b. Click the **Developer** section.  
|                    | c. Toggle the **JavaScript Log and Field Watcher** switch.  
| UI15                | a. Click the gear icon in the banner frame.  
|                    | b. Click **JavaScript Log and Field Watcher**.  
| UI11                | Click the debug icon ( Aç ) in the banner frame.  

A new pane opens at the bottom of the screen. It shows the JavaScript Log tab and may also show the Field Watcher tab.

2. If needed, select the **JavaScript Log** tab.

3. Click the clear icon ( X ) to clear the contents of the log, as needed.

**JavaScript debug window**

The JavaScript debug window appears in a bottom pane of the user interface when an administrator turns on debugging.

Use the debug window to access these tools.

- **JavaScript Log**: JavaScript that runs on the browser, such as client scripts, can include a call to `jslog()` to send information to the JavaScript log.
- **Field Watcher**: a tool that tracks and displays all actions that the system performs on a selected form field.

![JavaScript debug window](image)
Using the JavaScript debug window

The JavaScript debug window enables access to the JavaScript Log and the Field Watcher tools.

About this task

The steps to access the JavaScript debug window depend on which UI version you are using.

Procedure

1. Open the JavaScript debug window by navigating to the appropriate location for your version of the UI.

<table>
<thead>
<tr>
<th>UI 16</th>
<th>a. Click the gear icon in the banner frame.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>b. Click the Developer section.</td>
</tr>
<tr>
<td></td>
<td>c. Toggle the JavaScript Log and Field Watcher switch.</td>
</tr>
<tr>
<td>UI 15</td>
<td>a. Click the gear icon in the banner frame.</td>
</tr>
<tr>
<td></td>
<td>b. Click JavaScript Log and Field Watcher.</td>
</tr>
<tr>
<td>UI 11</td>
<td>Click the debug icon (扳手) in the banner frame.</td>
</tr>
</tbody>
</table>

The JavaScript debug window opens at the bottom of the screen. The tab that is currently active in the window is the last tab that was active when the window was closed.

2. Click a tab to use one of the debug window features.

   • JavaScript Log
   • Field Watcher

   Field watcher

JS Code Coverage Debug

The JS Code Coverage Debug application allows administrators and application developers to log the scripts triggered during a user session and then review which lines of code the system ran.

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Users with the js_coverage_debugger role can debug scripts without having to set breakpoints or review onscreen debug messages. Instead, the system saves script usage data in the JavaScript Code Coverage [sys_js_code_coverage] table. Each JavaScript Code Coverage record contains:

- The user session that called the script
- The script record the system called identified by table, sys_id, and script field
- The script record the system called identified by type and name
- The transaction that called the script
- The start time of the transaction
- The contents of the script field highlighted to indicate which lines the system ran

### Sample code coverage highlighting

```
var build = gs.getProperty("glide.buildname");
if (GlideStringUtil.notNil(build))
  build = build.substring(0,1).toLowerCase();

var collision = new GlideRecord("sys_embedded_help_content");
collision.addActiveQuery();
collision.addQuery("page", current.page);
collision.addQuery("modifier", current.modifier);
collision.addQuery("product", current.product);
if (current.isValidRecord() & GlideStringUtil.notNil(current.sys_id))
  collision.addQuery("sys_id", "!=", current.sys_id);
else
  collision.addNullQuery("qualifier");
if (current.version == "all" & GlideStringUtil.notNil(build))
  collision.addQuery("version", build).addOrCondition("version", "all");
else
  collision.addQuery("version", current.version);
collision.query();
if (collision.next()) {
  if (collision.canWrite())
    gs.addErrorMessage(gs.getMessage("Embedded Help Composite Key Validation"));
```

### JS Code Coverage highlighting

The JS Code Coverage application highlights script fields to indicate whether the system ran or skipped each line.
Sample code highlighting

```javascript
var build = gs.getProperty("glide.buildname");
if (GlideStringUtil.notNull(build))
    build = build.substring(0,1).toLowerCase();

var collision = new GlideRecord("sys_embedded_help_content");
collision.addActiveQuery();
collision.addQuery("page", current.page);
collision.addQuery("modifier", current.modifier);
collision.addQuery("product", current.product);
if (current.isValidRecord() & GlideStringUtil.notNull(current.sys_id))
    collision.addQuery("sys_id", "!=" current.sys_id);

if (GlideStringUtil.notNull(current.qualifier))
    collision.addQuery("qualifier", current.qualifier);
else
    collision.addNullQuery("qualifier");

if (current.version == "all" & GlideStringUtil.notNull(build))
collision.addQuery("version", build).addOrCondition("version", "all");
else
    collision.addQuery("version", current.version);
collision.query();
if (collision.next()) {
    if (collision.canWrite())
        gs.addErrorMessage(gs.getMessage("Embedded Help Composite Key Validation"));
```

The color of the highlight indicates how the system evaluated the code line.

### Meaning of code highlighting

<table>
<thead>
<tr>
<th>Highlight color</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Green</td>
<td>This is an executable line of code that the system ran during the session.</td>
</tr>
<tr>
<td>Red</td>
<td>This is an executable line of code that the system skipped for some reason. The system may have skipped an executable line of code because the necessary script conditions were not met or because the script function was never called. You may want to use the Script Debugger to determine why the system skipped the line of executable code.</td>
</tr>
<tr>
<td>Gray</td>
<td>This is a non-executable line of code such as white space, code comment, or a portion of an expression split across multiple lines that cannot run on its own.</td>
</tr>
</tbody>
</table>

Administrators and application developers can use this information to conduct more targeted debugging activities such as using the Script Debugger to determine why script conditions are not being met.
Activate JS Code Coverage Debug

You can activate the JS Code Coverage Debug plugin (com.glide.js.coverage) if you have the admin role.

Before you begin
Role required: admin

Procedure
1. Navigate to System Applications > All Available Applications > All.
2. Find the plugin using the filter criteria and search bar.
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click Install, and then in the Activate Plugin dialog box, click Activate.

   Note: When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

What to do next
To see the components the plugin installed, refresh the plugin form and select the Plugin Files related list.

Debug with JS Code Coverage Debug

Use JS Code Coverage Debug to record a user session and then review which scripts and lines of code the system ran.

Before you begin
Role required: admin or js_coverage_debugger

Procedure
1. Navigate to JS Code Coverage Debug > Enable Coverage.
   The system logs which scripts and code lines the system runs as well as displays session debug messages in the JS Code Coverage namespace.
2. Navigate to the table or page whose logic you want to test.

**Example**
For example, navigate to Incident > Create New.

3. Trigger the script or scripts you want to test.

**Example**
For example, create an incident with an associate CI item to test several business rules.

4. When you have completed testing, navigate to JS Code Coverage Debug > Disable Coverage.
The system stops logging script and code lines run.

The system displays the list of coverage data associated with the current user session.
6. Select the script or transaction you want to review.

### JavaScript Code Coverage fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Script Name</td>
<td>Displays the script run by table name, sys_id value, and script field.</td>
</tr>
<tr>
<td>Script Reference</td>
<td>Displays the script run by script type and name.</td>
</tr>
<tr>
<td>Transaction</td>
<td>Displays the transaction that called the script by thread ID and URI.</td>
</tr>
</tbody>
</table>

**Example**

For example, select the **Script Reference** Business Rule: incident events. The system displays the JS Code Coverage Debug record.

```javascript
if (current.operation() == 'insert' && current.comments.changes) {
  gs.eventQueue("incidentcommented", current, gs.getUserID(), gs.getUserName());
}
```

```javascript
if (current.operation() == 'insert') {
  gs.eventQueue("incident.inserted", current, gs.getUserID(), gs.getUserName());
}
```

```javascript
if (current.operation() == 'update') {
  gs.eventQueue("incident.updated", current, gs.getUserID(), gs.getUserName());
}
```

```javascript
if (current.assigned_to.nil() && current.assigned_to.changes()) {
  gs.eventQueue("incident.assigned", current,
  current.assigned_to.getDisplayValue(), previous.assigned_to.getDisplayValue());
}
```

```javascript
if (current.assignment_group.nil() && current.assignment_group.changes()) {
  gs.eventQueue("incident.assignment_group", current,
  previous.assignment_group.getDisplayValue());
}
```

```javascript
if (current.priority.changes() && current.priority == 1) {
  gs.eventQueue("incident.priority.1", current, current.priority,
  previous.priority);
}
```
7. Review the **Script** field to determine which lines of code the system ran.

**Example**
For example, the business rule added the incident.inserted event to the event queue.

**Results**
You determine which lines of code the system ran.

**What to do next**
Use the code coverage information to do more targeted debugging activities such as set breakpoints and review variable values with the Script Debugger.

### Packages Call Removal tool

The Packages Call Removal Tool provides modules to identify fields that might contain scripts, find scripts that contain Packages calls to ServiceNow Java classes, and to examine proposed script changes that eliminate those Packages calls. You can substitute your own changes in place of the proposed changes.

Packages calls to ServiceNow Java classes will be prevented in a future release. The Packages Call Removal tool helps prepare your instance to use the new API and includes the following scripts and pages:

- The Find Packages Fields script scans scripts for Packages calls to ServiceNow Java classes.
- The Find Packages Calls script proposes changes that remove Packages calls or replace them with GlideScriptable names.
- The Packages Call Items page lists, and enables you to work on, proposed changes to scripts.

The tool is available to users with the administrator role.

The tool can generate errors as it tries to generate preferred, scriptable alternatives for Packages calls to ServiceNow Java classes.

**Note:** If you intend to capture and migrate the changes that result from running the Packages Call Removal Tool, you should first create an update set.

### Activate the Packages Call Removal Tool

You must activate the Packages Call Removal Tool plugin to access the tool.
Before you begin
Role required: admin

Procedure
1. Navigate to System Applications > All Available Applications > All.
2. Find the Packages Call Removal Tool plugin using the filter criteria and search bar.
   You can search for the plugin by its name or ID. If you cannot find a plugin, you might have to request it from ServiceNow personnel. For more information, see Request a plugin.
3. Click Install, and then in the Activate Plugin dialog box, click Activate.

   Note: When domain separation and delegated admin are enabled in an instance, the administrative user must be in the global domain. Otherwise, the following error appears: Application installation is unavailable because another operation is running: Plugin Activation for <plugin name>.

Find a Packages call
After you run the Find Packages Fields script to define the list of fields to search for Packages calls, run the Find Packages Calls script to generate the list of fields with Packages calls to ServiceNow Java classes. The script also proposes changes.
Procedure

1. Click **(3) Find Packages Calls (script)** to execute a script that searches the fields for packages calls and populates the Packages Call Items list with proposed changes.

Example

2. Click **(4) Packages Call Items** to display the list of affected fields on the Packages Call Items page.

The Packages Call Items page lists the items with Packages calls, shows each item's current state, the table that contains the field, the affected record, the number of Packages calls contained in the field's script, and the number of errors that occurred when the proposed script was generated.
3. On the Packages Call Items page, click a record for any of the listed items to open the form and revise as described in Replacing Packages Calls.

As you work through the list, the **State** of the items are updated and the items are grouped by State:

- **Proposed**: A proposed revision exists for the field.
- **Error(red)**: One or more errors occurred when the proposed script was generated.
- **Rejected(gray)**: A proposed change has been rejected.
- **Completed(green)**: The field has been successfully revised to remove Packages calls to ServiceNow Java classes.
- **Canceled (gray)**: Since the proposed change was generated, either the original script has been changed to no longer require modification, or the original record no longer exists.

**Remove Packages calls from scripts**

The Packages Call Items page lists, and enables you to work on, proposed changes to scripts.
About this task
The Packages Call Items page lists all Packages calls to ServiceNow Java classes. From the page, you can open any item in a form to examine the proposed changes. You can accept a proposed change as-is, or edit the code as necessary to remove the Packages calls.

Initially, all items without errors are in the Proposed state. When you take an action on a field, its state is updated. As you work through the list, each field is tracked by its current state: Proposed, Error, Rejected, Completed, or Canceled. You work through all of the fields until all of the Packages calls to ServiceNow Java classes have been removed.

Procedure
1. To explore the details of an item in the list, click the link in the **State** column. The Package Migration Item form shows each line of the Original (current) version of the script and of the Proposed version. Lines with proposed changes are highlighted in yellow.

![Package Migration Item form](image)

2. Work through the items until all are in the **Completed**, **Canceled**, or **Rejected** state.

<table>
<thead>
<tr>
<th>To accomplish this for an item</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Accept the proposed change</strong></td>
<td><strong>Click Execute Change.</strong></td>
</tr>
</tbody>
</table>

© 2021 ServiceNow, Inc. All rights reserved. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
<table>
<thead>
<tr>
<th>To accomplish this for an item</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reject the proposed change</td>
<td>Click <strong>Reject Change</strong>. The change goes into the Rejected state. Rejecting a field allows you to defer action. To perform the change later, click <strong>Undo Rejection</strong>.</td>
</tr>
</tbody>
</table>
| Make the proposed change       | Click **Edit Proposed Version** to an editable script field where you can make changes. Below the edit field, a Diff pane displays line-by-line differences between the original and proposed versions. After you save changes, code is highlighted in the Diff pane as follows:  
  - **Yellow** indicates code differences between the original version and the proposed version.  
  - **Green** indicates lines added to the proposed version that were not in the original version.  
  - **Red** indicates lines in the original version that have been removed from the proposed version.  
  a. Make changes in the **Proposed version** pane.  
  b. To save the change and rerun the comparison, click **Save**. If the change generates an error, ServiceNow puts the field into the **Error** state.  
  c. To revert a change, click the text in the **State** column to reopen the field on the Packages Call Items page, and then click **Revert Change**. |

Glide object name

The names of the new Glide objects that replace Packages calls are derived from the Java package name used in the Packages call.

About this task

Although the tool automatically substitutes the appropriate new scriptable name for each Packages call it encounters, in some circumstances it can be useful to know how to manually replace a Packages call with its new scriptable object equivalent. Use the steps below to determine the new script object name from the Packages call name. The replacement objects include the same methods and properties as the objects they replace.

To determine the new object name:

Procedure

1. Note the third term in the Java package name. This is usually glide, but is sometimes snc or glideapp.

2. Drop all of the prefix terms, leaving only the last. For example, Packages.com.glide.monitor.AbstractBucketCollector becomes AbstractBucketCollector.

3. Capitalize the first letter of the term noted in the first step above and add it to the front of the term defined in step 2. For example, Packages.com.glide.monitor.AbstractBucketCollector becomes GlideAbstractBucketCollector and Packages.com.snc.cmdb.BaselineCMDB becomes SncBaselineCMDB.

4. Verify that the name is valid by executing a gs.print() command in Scripts Background, specifying only the name with no quotes. For example:

   gs.print( SncBaselineCMDB );

*** Script: [JavaClass com.snc.cmdb.BaselineCMDB]

Note that there are exceptions to this rule, such as "Glide", which replaces "Packages.com.glide.Glide", "TestExtension", which replaces "Packages.com.glide.junit.misc.TestExtension"; and "UINotification", which replaces "Packages.com.glide.ui.UINotification".

Glide object replacement list

This table lists the Glide classes and the Packages calls they replace.
**Note:** The publication of this list does not imply that these scriptable objects are for use by customers, consultants, and partners. The use of the Glide prefix does not imply that these scriptable objects are in the same category as or have the same status as objects such as GlideRecord. Except where documentation is provided in the API Reference, these undocumented APIs are not intended for general use, and ServiceNow, Inc., does not make any commitment to document them, answer questions about them, or maintain them indefinitely in their current form. Over time, ServiceNow, Inc., intends to migrate a subset of the functionality represented by these objects into the documented API and remove the rest.

### Packages Call Removal Tool error types

Possible error types generated by the Packages Call Removal Tool.

<table>
<thead>
<tr>
<th>Error message</th>
<th>Description</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Class Name Could</td>
<td>A line of script has what appears to be a Packages call (for example, the line contains Packages.com.glide) but on</td>
<td>This error type generally does not present a problem, but is nevertheless flagged as an error in case the script references...</td>
</tr>
</tbody>
</table>
### Error types (continued)

<table>
<thead>
<tr>
<th>Error message</th>
<th>Description</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not Be Parsed</td>
<td>examination there is insufficient text to parse out a class name that corresponds to a scriptable object name.</td>
<td>class that the parser, for whatever reason, cannot parse.</td>
</tr>
<tr>
<td>Class Does Not Exist</td>
<td>A line of script has an identifiable Packages call to a Java class that does not exist. This may be because it was incorrectly typed, or because the Java class no longer exists. Either way, the line of script is currently not doing anything and is potentially generating errors whenever it is run.</td>
<td>This error type usually identifies a script that is not doing what its author intended, or what it ever did. The original script should be revisited, and the invalid Packages call removed.</td>
</tr>
<tr>
<td>Class Is Not a Scriptable Class</td>
<td>A line of script has an identifiable Packages call to an existing ServiceNow Java class that is not currently marked as scriptable. The call cannot be replaced, because there is currently no corresponding scriptable name.</td>
<td>To convert this script, either rewrite the script so that it does not use the Java class or wait until ServiceNow, Inc., provides a scriptable name for the class.</td>
</tr>
<tr>
<td>Class Does Not Have a Scriptable Name</td>
<td>A line of script has an identifiable Packages call to an existing ServiceNow Java class that does not currently have a scriptable name.</td>
<td>This error is less likely to occur than a Class Is Not a Scriptable Class error; however, if it occurs, to convert this script, either rewrite the script so that it does not use the Java class or wait until ServiceNow, Inc., provides a scriptable name for the class.</td>
</tr>
<tr>
<td>Variable Name Being Assigned Conflicts With a Scriptable Name</td>
<td>A variable name has the same name as a scriptable name. For example, <code>var GlideSession = Packages.com.glide.sys.GlideSession.get();</code> would generate this error because the variable name <code>GlideSession</code> is the same as the scriptable name for the GlideSession Java class.</td>
<td>Before this script can be converted, the variable name must be changed wherever it occurs in the script. For this example, the line could be changed to <code>var gsession = Packages.com.glide.sys.GlideSession.get();</code> to remove the conflict. Also, be sure to change the variable name elsewhere in the script wherever it is used.</td>
</tr>
<tr>
<td>Internal Error - Unable To Find String</td>
<td>The tool is unable to find the script text it is currently evaluating for Packages call replacement.</td>
<td>This error type is very unlikely. If it does occur, examine your code and correct any errors. If the error message still appears, open an incident with Technical Support.</td>
</tr>
</tbody>
</table>

Now® Experience UI Builder

Now® Experience UI Builder is a web user interface builder. Use UI Builder to build pages for CSM Configurable Workspace, App Engine Studio-generated workspaces and portals, or custom web experiences using Now® Experience Components and custom web components.

[i] Note:

UI Builder is not yet capable of building or configuring out-of-the-box Service portals, like Employee Center. Continue to use the Service Portal Designer instead.

UI Builder overview
UI Builder overview

UI Builder quick start
UI Builder quick start video

Key features

Create pages for workspace or portal experiences

Create or customize pages for workspace and portal experiences. A page is a collection of components that make up a workspace or portal UI.
Create a variant of a page

Create variants of pages to target experiences for different audiences. For example, you can create a home page for agents, and a variant for managers at the same URL.

Use a full library of components

Use the UI Builder library of components to build your pages. You can add them to your page. Configure them any way you need and then connect your company data to them.

Connect data to your components
Bind data to your components using data resources to dynamically expose your data from tables, records, or other elements on your page. Data resources let you reuse your components.

**Modify the layout of a page**

Create any type of page design by changing the layout of the page.

**Add styling to your component**

Use CSS to change the visual style of a component in your workspace or portal experience. For example, you can add a background color to a container component.
Get started

<table>
<thead>
<tr>
<th>Explore</th>
<th>Use</th>
</tr>

<tr>
<td>Learn about UI Builder concepts and features.</td>
<td>Learn how to build pages in UI Builder.</td>
</tr>
</tbody>
</table>

Exploring UI Builder

Explore the areas of Now® Experience UI Builder to get you set up and creating pages quickly.

Check out the UI Builder quick start topic to understand the basics of UI Builder. If you want a deeper understanding of UI Builder, go through the tutorial to learn how to create your first page.

Find information relating to UI Builder audiences, security and roles settings like application scope and domain separation, as well as experience settings.

See how you can leverage UI Builder with CSM Workspace and portal experiences.

UI Builder quick start

This quick start guides you through the process of creating your first page in Now® Experience UI Builder. Creating your first page is the first step in understanding how to build user interface pages for your workspace or custom portal experiences.

Before you begin
Role required: ui_builder_admin

In this UI Builder quick start, you perform the following tasks to build your first page in UI Builder.

- Start UI Builder.
- Create a page for your workspace or custom portal experience. For more information about creating pages, see Create a page.
- Change the layout of the page to have two columns. For more information about layouts, see Work with layouts.
• Build your page by adding two container components. For more information about components, see Work with components.
• Rename your container components in the content tree.
• Add a heading component in one container. Add an image component in a second container.
• Save your page.
• Preview your page to see how it looks in a browser.

Procedure
1. Navigate to Now Experience Framework > UI Builder. You can also type UI Builder directly in the Filter navigator.

2. Select an experience you want to work in from the UI Builder home page. If you do not see any experiences listed in which to work, contact your administrator to get access to an experience, or create an experience. For more information, see Create an experience.
3. Create a page.
To do this task | Do the following

| a. Click **Menu** and select **Create Page**. |
| - UI Builder | - Menu | - Help | - URL (now/demo) |
| - Create page |
| - Create variant |
| - Duplicate variant |
| - Configure |
| - Edit page settings |
| - Edit variant settings |
| - Edit experience settings |
| - Developer |

| b. Type the name of your new page in **Create a page > Name of page**. The name can be anything you want. In this example, you can type **My First Page**. |

| c. In the **Path** field, a path is automatically entered based on your page name. In this example, the Path is **my-first-page**. The path is the URL of the page. You can change this path to anything you want, but the path must be unique. The path has to be lowercase and contain no spaces. The **URL preview** shows what the path of your page will be. |

| d. Skip the page template option as you are creating a blank page to start. |

| e. The application scope defaults to the scope that a user is currently in within the Now Platform®. For more information, see **Security and roles in UI Builder**. |

| f. Select **Create**. |

| g. After your page is created, you can change advanced settings such as the **URL settings** and **Variant** settings. For this quick start, you can skip these advanced options and select **Done**. For more information on changing advanced settings, see **Create a page: Advanced settings**. |
Congratulations! You have created your first page! The page is empty of content. You add components to the page to build functionality to it. Components are the building blocks of a page. UI Builder comes with many components ready for you to add to your page. Components can be as simple as a **Heading**, or as complex as a **List**.

4. Change the layout of the page to a two-column layout so your two containers show side by side on the page. For more information about layouts, see Work with layouts.

</tr>
<tr>
<td>iii. Change the <code>Component ID</code> to <code>container_for_heading</code> and select <code>Apply</code>. For more information on component IDs, see <code>Component ID</code>.</td>
</tr>
</tbody>
</table>
To do this task

<table>
<thead>
<tr>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td>Notice the container name changes to <strong>Container for Heading</strong> in the content tree. The content tree is an important concept. The content tree is an easy way to see the structured layout of your page. The content tree is especially important when you have multiple components on your page. You select the component in your content tree to highlight the component on the page, making it easier to build your page. You can do a text search for a component.</td>
</tr>
</tbody>
</table>

You have successfully added your first container component to your page.

6. Add a **Heading** component to your left column container.
To do this task | Do the following
--- | ---
You can add components to the page in different ways. For more information on the ways you can add components to your page, see [Ways to add a component to a page](#).

**a.** Select the + button in the middle of your container and type `Heading` in the search.

![](image)

**b.** Select the **Heading** component to add it to your container. A heading component is a way to add text or a title to your page.

c. Select your new **Heading** component to highlight it.

d. Select the pencil icon to see the **Component label** and **Component ID**. You can change these to anything you want, as long as they are unique.

e. Configure your **Heading** component. Component authors configure components to expose the appropriate properties required to set up their components.

   **i.** In the **Label** field, enter the text of your heading, such as *My new heading*.

   **ii.** Leave the Level as 1, and Style as **Header-primary**.
### To do this task

<table>
<thead>
<tr>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Add a container component to your right-column container</strong></td>
</tr>
</tbody>
</table>

#### iii. The Style changes the size of the heading text. For example, if you select **Header-secondary**, the text is smaller. Different headings sizes are useful if you have two headings and want the second heading smaller than the primary heading. For more information on configuring components, see **Configure components**.

For more information about configuring components, see, **Now Experience Components**.

f. Select **Save**. Save your page often as you work.

You have added a heading component to your page.

7. Add a second container in the right column of your page.

You can add components to the page in different ways. For more information on the ways you can add components to your page, see **Ways to add a component to a page**.
To do this task | Do the following
--- | ---
a. Similar to before, select the + button in the right-column container. Type `Container` in the search and select `Container` to add a new container to your container.
b. Rename the container.

i. Select the `Container 1` component in the content tree to highlight your new container on the page.

ii. Select the pencil icon in the right configuration panel and name your `Component label` to `My second container`.

iii. Change the `Component ID` to `my_second_container`. For more information on component IDs, see `Component ID`.

iv. Select `Apply`.

c. Look in the content tree to see your changes. Notice the container name changes to `My second container`. You can easily find your second container by name. Or you can do a text search for the component.
<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>d.</strong> Select <strong>Save</strong>. It is always a good idea to save your page often as you work.</td>
<td></td>
</tr>
</tbody>
</table>

**8.** Add an image component to your page. An image is a nice way to add a visual for your page. In this quick start, you add a stock photo that comes with UI Builder. But you can add any image that is available to you.

<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>8.</strong> Add an image component to your right-column container</td>
<td>You can add components to the page in different ways. For more information on the ways you can add components to your page, see <em>Ways to add a component to a page.</em></td>
</tr>
<tr>
<td></td>
<td><strong>a.</strong> Add the image component to the second container. Select the + in your container.</td>
</tr>
<tr>
<td></td>
<td><strong>b.</strong> In the <strong>Search</strong> field, start typing <strong>Image</strong> until you see the <strong>Image</strong> component, then select the component. A default image is loaded. You can add your own image by adding a URL to the image. You can use images hosted on the Internet or images in the <strong>Now Platform®</strong>. If you use an image hosted on an external site, you must use <strong>https</strong> protocol for security.</td>
</tr>
<tr>
<td></td>
<td><strong>c.</strong> Name your <strong>Image</strong> component to make it easier to identify it in the content tree as you work.</td>
</tr>
<tr>
<td></td>
<td><strong>i.</strong> Select the pencil icon in the right configuration panel to change the component details.</td>
</tr>
<tr>
<td></td>
<td><strong>ii.</strong> In the <strong>Component label</strong> field, type <strong>My image</strong>.</td>
</tr>
</tbody>
</table>
To do this task | Do the following
---|---
**iii.** For Component ID, type `my_image`. For more information on component IDs, see **Component ID**.
**iv.** Select **Apply**.
**v.** Save your page.

For more information about configuring components, see, **Now Experience Components**.

You added an image component to your page.

**9.** Save your new page one last time.

<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
</table>
| **Save your page** | **a.** In the far right corner of UI Builder, select **Save**.  
**b.** Now that you saved your page, you can access it in your experience at any time. |

**10.** Generate a preview of your page.
<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. In the right corner of the URL field, select <strong>Open</strong>.</td>
<td><strong>b.</strong> Your page generates a preview of how it looks in your Workspace or portal experience. The page preview opens in another tab of your browser.</td>
</tr>
</tbody>
</table>

Open your page to preview it

![Image of UI Builder interface with a preview of a page with a heading and an image.]()

Congratulations! You completed the UI Builder quick start.

**Results**

1. Created your first page in UI Builder.
2. Changed the layout of your page to have two columns.
3. Added your first container component to the left column. You changed the label for the container.
4. Added a **Heading** component as a title to your left component. You changed the text of the heading. You also changed the label.
5. Added another container component to your right column. You changed the label for the container.
6. Added an **Image** component. You changed the label of the image component.
7. Saved your new page.
8. Previewed your page in the browser.

You successfully completed the UI Builder quick start!

**UI Builder tutorial**

Learn how to use the basics of Now® Experience UI Builder to create a page called My Tutorial.

**Before you begin**

Role required: ui_builder_admin

In this UI Builder tutorial, you perform the following tasks to build a page in UI Builder.

- Start UI Builder.
- Create a page for your workspace or custom portal experience. For more information about creating pages, see Create a page.
- Change the layout of the page to have two columns. For more information, see Work with layouts.
- Build your page by adding two container components.
- Rename your container components in the content tree.
- Add a **Heading** component and a **Button** component to the first container. Add a **data visualization component** to the second container. For more information about components, see Work with components.
- Configure your components as follows:
  - Link the button to the ServiceNow® website.
  - Connect the **Data visualization** component to a data source to display task data. For more information about data resources, see Work with data resources.
- Save your page often.
- Preview your page to see how it looks in a browser.
Procedure

1. Navigate to **Now Experience Framework > UI Builder**. You can also type **UI Builder** directly in the **Filter navigator**.

2. From the UI Builder home page, choose an experience you want to work in. If you do not see any experiences listed in which to work, contact your administrator to get access to an experience or create an experience. For more information, see Create an experience.

3. Create a page.

<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>a.</strong> Click <strong>Menu</strong> and select <strong>+ Create Page</strong>.</td>
<td></td>
</tr>
<tr>
<td><strong>b.</strong> Enter the name of your new page. The name can be anything you want. In this example, you can type <strong>My tutorial page</strong>.</td>
<td></td>
</tr>
<tr>
<td><strong>c.</strong> In the <strong>Path</strong> field, a path is automatically entered based on your page name. In this example, the <strong>Path</strong> is <strong>my-tutorial-page</strong>. The path is the URL of the page. You can change this path</td>
<td></td>
</tr>
<tr>
<td>To do this task</td>
<td>Do the following</td>
</tr>
<tr>
<td>----------------</td>
<td>------------------</td>
</tr>
</tbody>
</table>
| to anything you want, but the path must be unique. The path has to be lowercase and contain no spaces. The **URL preview** shows what the path of your page will be. | Create a page  
First, let's set up this page.  

<table>
<thead>
<tr>
<th>Name of page</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>My tutorial page</td>
<td>my-tutorial-page</td>
</tr>
</tbody>
</table>

URL preview  
/now/demo/my-tutorial-page  
d. Skip the page template option as you are creating a blank page to start.  
e. The application scope defaults to the scope that a user is currently in within the Now Platform®. For more information, see Security and roles in UI Builder.  
f. Select **Create**.  
g. After your page is created, you can change advanced settings such as the **URL settings** and **Variant** settings. For this quick start, you can skip these advanced options and select **Done**. For more information on changing advanced settings, see Create a page: Advanced settings.
Congratulations! You created your tutorial page! The page is empty of content. You add components to the page to build functionality to it. Components are the building blocks of a page. UI Builder comes with many components ready for you to add to your page. Components can be as simple as a **Heading**, or as complex as a **List**.

4. Change the layout of the page to a two-column layout so your two containers show side by side on the page. For more information about layouts, see **Work with layouts**.

<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Change the layout of the page to two columns</strong></td>
<td>a. Select the <strong>Body</strong> level of the <strong>Content</strong> tree to highlight the page.</td>
</tr>
<tr>
<td></td>
<td>b. In <strong>Page configuration</strong> to the right of the main page area, select <strong>Layout</strong> to see the layout options for the page.</td>
</tr>
<tr>
<td>To do this task</td>
<td>Do the following</td>
</tr>
<tr>
<td>-----------------</td>
<td>------------------</td>
</tr>
<tr>
<td>c. Select the two-column layout option.</td>
<td></td>
</tr>
<tr>
<td><strong>Change layout of page</strong></td>
<td></td>
</tr>
</tbody>
</table>

5. Add a container component to the left column of your page. A container is what holds your components. Think of a container as an area of the page where you add information, images, or functionality (your components). You can have as many containers on a page as you want, with as many containers within containers, with as many components in the containers.

<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. Select the + Add component button in the middle of the left column on your page. Type container into the search and select the Container component.</td>
<td>You can add components to the page in different ways. For more information on the ways you can add components to your page, see Ways to add a component to a page.</td>
</tr>
</tbody>
</table>
b. Name your left container to make it easier to identify in the content tree as you work.
   i. Select Container 1 in the Content tree to highlight the container.
   ii. Select the pencil icon in the right configuration panel and in the Component label field, type Left container.
   iii. Change the Component ID to left_container and select Apply. For more information on component IDs, see Component ID.
<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
</table>

Notice the container name changes to **Left container** in the content tree. The content tree is an easy way to see the structured layout of your page. The content tree is especially important when you have multiple components on your page. You select the component in your content tree to highlight the component on the page, making it easier to build your page. You can also do a text search for a component.

You have successfully added your first container component to your page.

6. Add a **Heading** component, and a **Button** component to your left column container.
To do this task | Do the following
---|---
You can add components to the page in different ways. For more information on the ways you can add components to your page, see Ways to add a component to a page.

a. Select the + button in the middle of your container and type `Heading` in the search.

b. Select the `Heading` component to add it to your container. A heading component is a way to add text or a title to your page.

c. Select your new `Heading` component to highlight it.

d. Select the pencil icon to see the `Component label` and `Component ID`. You can change these to anything you want, as long as they are unique.

e. Configure your `Heading` component. Component authors configure components to expose the appropriate properties required to set up their components.

i. In the `Label` field, enter `My Tutorial` as the heading text.

ii. Leave the Level as 1, and Style as `Header-primary`. The Style changes the class of the heading text, like font, weight, and color. For
<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
</table>

- **Example:** If you select **Header-secondary**, the text is smaller. Different headings sizes are useful if you have two headings and want the second heading smaller than the primary heading.

Add and configure a button component to your left-column container

Add a **Button** component to your page. Configure the button by changing the text and the way it looks. Then change what happens when you click the button by adding an event handler for the button. The event handler adds an action to the button to link to the ServiceNow® home page. So when you click the button, the ServiceNow® home page opens in a new tab of your browser. For more information about configuring components, see [Now Experience Components](#).

1. Select the `+` on the bottom edge of your container to add a component beneath the container.
2. In the **Search** field, start typing **Button** until you see the **Button** component, then select the component to add it to your container. For more information on adding components to
<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td>your page, see Ways to add a component to a page.</td>
<td></td>
</tr>
<tr>
<td>c. Select the pencil icon to see the Component label and Component ID. You can change these to anything you want, as long as they are unique.</td>
<td></td>
</tr>
<tr>
<td>d. Configure the button component as follows.</td>
<td></td>
</tr>
<tr>
<td>i. Change the Size to Large.</td>
<td></td>
</tr>
<tr>
<td>ii. In the Label field, type Home Page to change the name of your button.</td>
<td></td>
</tr>
<tr>
<td>iii. In the Icon drop down, select Home Outline. You can search for Home Outline instead of scrolling through the list.</td>
<td></td>
</tr>
<tr>
<td>e. Add an event handler to configure what action applies to the button.</td>
<td></td>
</tr>
<tr>
<td>i. Select the Events tab.</td>
<td></td>
</tr>
<tr>
<td>ii. Under Button clicked, select + Add a new event handler.</td>
<td></td>
</tr>
</tbody>
</table>
To do this task | Do the following
---|---

| iii. Under Inherited event handlers, select **Link to destination**. |
| iv. Select **Select destination**. |
| v. In the **Configure navigation** screen, select **External URL**. |
| vi. Type your URL. For this tutorial, type `https://www.servicenow.com` **Select OK**. |
| vii. Select **Add**. |

For more information about event handlers, see **Work with events**.

f. Select **Save**. It is always a good idea to save your page often as you work.

You added and configured the **Heading** and **Button** component for your page.
7. Add a second container in the right column of your page.

<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add a container component to your right-column</td>
<td>You can add components to the page in different ways. For more information on the ways you can add components to your page, see Ways to add a component to a page.</td>
</tr>
<tr>
<td>a. Similar to before, select the + button in the right-column container. Type Container in the search and select Container to add a new container.</td>
<td></td>
</tr>
<tr>
<td>b. Rename the container.</td>
<td>i. Select the Container 1 component in the content tree to highlight your new container on the page.</td>
</tr>
<tr>
<td></td>
<td>ii. Select the pencil icon in the right configuration panel and name your Component label to My visualizations container.</td>
</tr>
<tr>
<td></td>
<td>iii. Change the Component ID to my_visualizations_container. For more information on component IDs, see Component ID.</td>
</tr>
<tr>
<td></td>
<td>iv. Select Apply.</td>
</tr>
</tbody>
</table>
To do this task | Do the following
--- | ---
c. Look in the content tree to see your changes. Notice the container name changes to **My visualizations container** in the content tree. You can easily find your second container by name. You can also do a text search for a component.
8. Add a **Data visualization** component to the container. A data visualization component contains data that you display in a visual manner. Configure the data visualization component parameters. Then, add a data resource to it.

<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>You can add components to the page in different ways. For more information on the ways you can add components to your page, see Ways to add a component to a page.</td>
</tr>
<tr>
<td>a.</td>
<td>Select the + to add a component to your second container.</td>
</tr>
<tr>
<td>b.</td>
<td>In the <strong>Search</strong> field, start typing Data visualization until you see the Data visualization component, then select the component to add it to your page.</td>
</tr>
<tr>
<td>c.</td>
<td>Select the pencil icon to see the <strong>Component label</strong> and <strong>Component ID</strong>. You can change these to anything you want, as long as they are unique.</td>
</tr>
<tr>
<td>d.</td>
<td>Add a data resource to your data visualization component to bring in customer account data.</td>
</tr>
</tbody>
</table>

Add and configure a data visualization component to your right-column container

  **c.** See the heading in the left column of your page.
  
  **d.** Select the **Home Page** button. The ServiceNow® home page opens in another browser tab. Close the browser tab to go back to your preview page.
  
  **e.** See the customer account data visualization in the right column of your page.

---

Congratulations! You completed the UI Builder tutorial.

**Results**

1. Created a page in UI Builder.
2. Changed the layout of your page to have two columns.
3. Added the first container component to the left column.
4. Changed the label for the container.
5. Added a **Heading** component as a title to your left component.
6. Added a button component below your heading component.
   • Configured your button.
   • Added an event handler for your button.
   • Added an event handler to set up a link to a web page. When you click the button, it opens the web page.

7. Added another container component to your right column.

8. Changed the label for the container.

9. Added a Data visualization component.
   • Configured the data visualization component.
   • Added a data resource to bring in task data.

10. Saved your new page.

11. Previewed your page in the browser.

**Understanding your audiences**

Learn how to apply the correct audiences to your Now® Experience UI Builder pages.

**Audiences**

Understanding your audiences in UI Builder is an important part of creating pages. The audience defines who can see your pages. You create pages for targeted experiences tailored to audiences and roles such as agents and managers. For example, you may want create a page for agents to solve issues for your employees. You want to ensure that only people who have the agent role can see the page.

Audiences are generally made of allow/deny lists that include role and domain. But, if the UX Framework User Criteria plugin is enabled, audiences can also target the following:

• Role
• Group
• User
• Company
• Department
You can set audiences to fit a specific role based on one or more criteria. For example, you could create an audience for an ITSM user in Europe who is not a manager.

Set an audience in UI Builder when you create your page or page variant. You can also set the priority of the audience record. The lower the number the higher the priority. Ensure the Active check box is selected to make this page active.

If you do not see an audience that you need, you can click Open audiences in platform to define an audience in the Now Platform®.

- Choosing an audience from the list in the Audience field.

- Selecting Open audiences in platform to edit or create an audience record in the Now Platform®.
• If you have multiple audiences, define the **Order** for each audience record. The order defines the importance of each audience record. For example, a CSMManager could have a higher priority than a CSM Consumer Agent.

• Ensuring the **Active** check box is selected to make this page active.

**Security and roles in UI Builder**

Set up the security and roles for your UI Builder instance.

Security and roles in Now® Experience UI Builder are controlled through your applications scope, domain separation, and protection policy settings.

**Roles**

Roles control access to features and capabilities in UI Builder. The admin role provides access to all features and capabilities. After access has been granted to a role, all the groups or users assigned to the role are granted the access. Roles can contain other roles, and any access granted to a role is granted to any role that contains it.

**Application scope**

Application scoping protects applications by identifying and restricting access to application files and data. Administrators can specify what parts of an application are accessible to other applications, which helps to protect data and application files. In UI Builder, System administrators and developers set application scope when creating a page. Note, you cannot change the application scope after creating the page, so choose your scope carefully.

Changing the scope in UI Builder also changes the scope in the Now Platform®, and vice-versa.

When creating a page, it is important for admins and developers to be aware of the scope you are in for the workspace or portal experience. Choose the correct application scope for your experience. The scope picker is to the right of the URL field. The scope defaults to the scope that the user is currently in within the Now Platform®.
If you change to a different scope while in a page, you will be notified that you are in a different application scope from the one the page was created in.

**Delegated developers for UI Builder**

If you have the application-specific admin role or the system-level admin role, you can delegate application development in ServiceNow® Studio to designated developers at the UI Builder application level.

For more information on how to designate UI Builder application development to a delegated developer, see Delegate development and deployment permissions to personnel.

For more information on delegated developers, see Delegated development and deployment.

For more information about adding an experience for UI Builder from ServiceNow® Studio, see Add an experience to UI Builder from Studio.

**Protection policy**

A protection policy prevents anyone from modifying and/or copying an application file or its related record. A protection policy is typically used when the author of an application is different than the company that will use the application. UI Builder will notify you if you try to modify a protected record.

**UI Builder and Customer Service Management Workspace**

Use Now® Experience UI Builder to create pages for your Customer Service Management Workspace experience.

A workspace is a collection of tasks and workflows in a single focused working area that enables a user to efficiently complete an entire job. It includes tools that a user can employ to quickly and easily assist customers and resolve questions and issues. A workspace also includes features that enable a user to be more efficient, including a multi-tab interface for managing multiple cases and a contextual display that provides quick orientation to the current task.

You can use UI Builder to create pages for your CSM Workspace experience. UI Builder provides CSM-related base system components that you can use to build workspace pages.

You do not create a CSM Workspace in UI Builder. You only use UI Builder to build pages for CSM Workspace experiences.

To create a page in UI Builder for a Workspace experience, you navigate to Now experience framework > UI Builder to open UI Builder.
The UI Builder home displays your available experiences under **My experiences**. If you are working in a Workspace experience, you should see the experience listed here.

For more information, see [Workspaces in Customer Service Management](#).

For information on how to change your Workspace experience settings from within UI Builder, see [UI Builder Workspace experience settings](#).

**UI Builder and portals**

Use Now® Experience UI Builder to create pages for your stand-alone, custom portal experiences.

You can use UI Builder to create and edit pages in your stand-alone, custom portal experiences. Creating pages for your custom portal experience is the same as creating pages for workspaces.
Note: UI Builder is not yet capable of building or configuring out-of-the-box Service portals, like Employee Center. Continue to use the Service Portal Designer instead.

To create a page in UI Builder for a portal experience, you navigate to Now experience framework > UI Builder to open UI Builder.

The UI Builder home displays your available experiences under My experiences. If you are working in a portal experience, you should see the portal experience listed here.

Once you select a portal experience, you can start editing pages, modifying pages, or creating new pages for that portal experience within UI Builder.

For information on how to change your portal experience settings from within UI Builder, see Portal experience settings.

The new framework for UI Builder
Learn about the framework that Now® Experience UI Builder is built on.
UI Builder is built on web standards, and provides a declarative way to build and configure pages for Workspace or Custom Portal. The framework is built on design patterns through reusable components, which allows customers a WYSIWYG experience for extending their experience.

The new framework that UI Builder sits on is powerful, extensible, and lets you build amazing pages for your experience.

**Preview a page in UI Builder**

Learn how to preview a page in Now® Experience UI Builder.

When you create or edit a page in UI Builder, you can open it as a preview to see what the page will look like as a web page. This is a great way to see how your page looks as you build it.

For example, if you add a Delete record button that opens a modal asking a user to confirm the deletion, you may want to open the page in runtime to ensure that the button and modal are displayed the way you want them to. To preview a page, first save your page, then select the Open button to the right of the URL field.

Your page will open as a web page. You can test your page as if it was live on a site. Click the components that you added to ensure they work as expected, check that the data resources are available, the layouts are set up correctly, and so on.

Previewing a page in UI Builder is a powerful tool to help you test your pages.

**Domain separation and UI Builder**

Domain separation is supported for UI Builder. Domain separation enables you to separate data, processes, and administrative tasks into logical groupings called domains. You can control several aspects of this separation, including which users can see and access data.

Role required: ui_builder_admin

**Support level: Standard**

- Includes **Basic** level support.

- Business logic: The service provider (SP) creates or modifies processes per customer. The use cases reflect proper use of the application by multiple SP customers in a single instance.

- The instance owner must configure the minimum viable product (MVP) business logic and data parameters per tenant as expected for the specific application.
Sample use case: An admin must be able to make comments required when a record closes for one tenant, but not for another.

For more information on support levels, see Application support for domain separation.

Overview

Now® Experience UI Builder is a WYSIWYG web user interface builder. UI Builder enables developers to build new pages or customize existing pages for web-based workspace and portal experiences using Now® Experience Components and custom web components. In addition, UI Builder supports Domain Separation, which is the ServiceNow® instance-wide multi-tenant architecture.

For more information on domain separation, see Domain separation explained.

Enable developers or dashboard builders in domain separated environments to safely create UI application screens or dashboards while in the same browser window. Domain Separation in UI Builder works similarly to application scope to help administrators safely create or edit in a multi-tenant environment.

It is important to understand a key principle to maintaining a stable, healthy, and scalable ServiceNow® instance, where Domain Separation is installed. The primary principle is standardization. Standardization means a common configuration that the majority of the instance operates by. When an instance has hundreds or thousands of domains, managing them successfully requires rigorous governance. Domain-specific configurations should be done only if they are deemed necessary by the instance owners. Generally, most instances should follow the common instance configuration. Doing so provides a more uniform experience across the instance. It also lets instance owners minimize code sprawl that slows the adoption of new ServiceNow® features included as part of release upgrades.

How domain separation works in UI Builder

Domain separation in UI Builder works similarly to application scope to help administrators safely create or edit in a multi-tenant environment.

UI Builder is comprised of a framework of interlocked components that you use to create web-based workspaces, dashboards, or portals. While the application supports domain separation, it does not mean every component or table is domain separated, which is important for instance owners to understand.

If the current domain does not match the domain of the variant or dashboard, the record is read-only. If a user has access to the domain, they can choose to switch their domain to the domain of the record. Alternatively, users can edit the
record. Editing the record temporarily forces the user session into that record’s domain. They can then make edits without fear of accidentally creating an override.

The following diagram shows what is (in green) and is not (in blue) domain separated in UI Builder.

Not shown in the diagram are viewports, declarative actions, and screen applicabilities, which are domain supported as process.

Data and Process/UI Separation are important when considering domain separation architecture. UI Builder fully supports data and process/UI separation, and any data (records) displayed in the web-based workspace, dashboard or portal experiences.

For example, a change request that belongs to the domain of Acme only shows for users who have access to the domain of Acme in an experience built using UI Builder. Conversely, if an application does not support data separation, its records won’t be domain separated by the workspace or portal experience.

Process/UI separation tables that form the underpinning framework in UI Builder are process separated, and a sys_override column exists on those tables. For example, if a page is created in Global, any changes to the logic created and saved in a sub domain results in an override.

For items that are not domain separated, any change to the logic globally affects any page or dashboard that references its content. Understanding domain separation is critical when interacting with these elements.
Domain Selection menu, messaging, and managing overrides

When designing a workspace, dashboard, or portal experience using the UI Builder (including Dashboard Builder), a system administrator or ui_builder_admin has access to a Domain Selection menu in UI Builder. A system administrator or ui_builder_admin should switch to the proper domain prior to creating, editing, or overriding a variant or dashboard page.

By default, the ui_builder_admin role does not have access to the Domain Selection menu; it must be coupled with a role that grants access, such as ITIL, or it can be added via system property. For more information, see Restrict access to the domain picker.

In addition, the Domain Selection menu also shows Expand/Collapse Domain Scope, that is displayed while the system administrator or ui_builder_admin is in Global. Select Expand to show any variant or dashboard that has been overridden, or exists as a standalone in a sub domain. Select Collapse to only show variants or dashboards created in Global.

Lastly, domain hierarchy is available from the Domain Selection menu. For deep-domain hierarchies, the user may have to collapse the branches of the domain hierarchy to physically select the domain. In these environments, perform a search to find the domain.

UI Builder has governance controls for editing and overriding variants or dashboards, similar to the way application scope is handled. Both application scope and domain scope are handled concurrently in UI Builder.

For example, if a variant was created in Global, but the current domain of the system administrator is set to Acme, then that variant is read-only. As long as that screen is not in a private scope that prevents editing, the system administrator or ui_builder_admin have two options. They can temporarily transact into the global domain if they have access to Global. Or, they can create an override.

You can edit the domain separation to make quick changes to the variant or dashboard and its content. When you edit the domain, you temporarily transact into the same domain scope as the variant or dashboard. Going into the same scope prevents accidental overrides when modifying certain settings such as Name, Order, Event Mappings, Page Definition configurations) tied to the variant. While in edit mode, not all settings are available in page management. For full capabilities, switch into the correct domain prior to editing the record.

Create Override allows a system administrator or ui_builder_admin to create an override of an existing variant or dashboard. Create an override of a variant or dashboard to perform an extensive copy of the page definition content, minus screen conditions and audiences in the user’s currently selected domain. The sys_override column is then updated appropriately.
Viewports which are variants in of themselves, are domain separated, and are typically nested inside page definition content. Some viewports may not copy over. For example, a viewport (displayed as a tab set) that was created as an override in a domain of a Global viewport would not be carried in the page definition content during the override creation process.

As screen conditions and audiences may be specific to a domain, this content is not carried over during the override creation process. A screen prompts the system administrator or ui_builder_admin to create screen conditions and audiences.

A user cannot create an override of a variant or dashboard in Global if the item exists in a sub domain, or if an override exists for that variant or dashboard in the same sub domain.

Once the override and the conditions and audiences are set, the content and configurations can be configured as needed. As standard to domain separation, the override is no longer affected by any changes done to the original variant or dashboard. The workspace, dashboard, or portal experience displays these overridden configurations if the user’s current domain session is within the affected domain or sub domains where this override was created. Audiences further determine what a user may or may not see.

In addition, a user can access the domain hierarchy to view existing overrides from higher domains. For example, Global <- Top <- Acme <- Current domain. If no overrides exist, the default variant or dashboard are displayed. The exception is if the default variant or dashboard is in a child domain or a peer domain.

If you select **Expand Domain Scope** while in Global, all variants and overrides in sub domains are shown as previously mentioned.
System administrators and ui_builder_admin can see what has been created in the ServiceNow® platform.

**Viewports and domain separation**

Viewports are variants that can be nested in page definition content. They can be created as a common configuration in Global, or can be overridden per sub domain.

**Declarative actions and domain separation**

Declarative Actions can be overridden per domain as well. A system administrator or ui_builder_admin should select the appropriate domain prior to creating a domain specific declarative action override.

**Themes and domain separation**

You can apply themes to a workspace or portal experience in UI Builder Experience Settings based on domain. However, prior to entering Experience Settings as a system administrator or ui_builder_admin, ensure that the appropriate domain is selected first.

Once the correct domain is selected, go to Experience Settings and select the theme that is to be applied. All sub domains have this theme applied unless specifically overridden.

**Create an experience for UI Builder**

Learn how to create a new workspace or portal experience for Now® Experience UI Builder in the ServiceNow platform.

**Before you begin**

Role required: ui_builder_admin

**About this task**

This task shows you a basic example of how to create a new workspace or portal experience for UI Builder. This example creates an experience called My App to demonstrate the process.
Procedure

1. Navigate to **Now Experience Framework > UI Builder**.

2. From the UI Builder home page, select **+ Create experience in Platform**. You leave UI Builder and go to the ServiceNow platform to create the experience.

3. Select **New** to create a new UX Application record for your new experience.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title</td>
<td>Add a title for your new experience. For this example, it is <strong>MyApp</strong>.</td>
</tr>
<tr>
<td>Page</td>
<td>Search for the page you want to create the experience for. In this example, select <strong>UI Builder</strong>.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>App Shell UI</td>
<td>You must choose an app shell in order for the experience to work. For example, you could choose a workspace or portal app shell. The app shell is the wrapper of the page contents, which is similar to the functionality of a web page. The app shell can show things like the logo of your company, user preferences, the search icon. For more information, see App Shells for UI Builder.</td>
</tr>
<tr>
<td>URL path</td>
<td>Add a path for your experience. The path appends to the end of the URL parameter of your experience. For example, if you used MyApp as the title for your experience, you could type my/app for the path.</td>
</tr>
<tr>
<td>Admin panel</td>
<td>a. Choose a table to associate to your experience from the list of tables, such as UX App Configuration.</td>
</tr>
<tr>
<td></td>
<td>b. Search for a document, or create a new document. If you create a new document, click the magnifying glass icon, then select New. In the simple MyApp example, you would type My App in the Name field, then select Submit.</td>
</tr>
<tr>
<td></td>
<td>c. Select OK in the Select the document field.</td>
</tr>
</tbody>
</table>
4. Select **Submit** to submit your new experience record.

5. Go back to your UI Builder home page. Refresh the page. You see your new experience listed under *My Experiences*. In this simple example, you see My App listed.

**App Shells for UI Builder**

Understand what app shells are, what app shells are available for UI Builder, and why you would pick one over another.

**App shells**

An app shell is the wrapper of the contents of an experience page. An app shell contains functionality similar to a web page. For example, an app shell can show things in a header or footer of your experience, such as a logo for your company, user preferences, a search icon, configuration icon, user menu, and so on.

An app shell is required for UI Builder.

The app shell defines whether your experience has a workspace or portal design. A workspace is a graphical user interface that puts multiple tools on one page for handling requests from users. A portal is a page where users can add requests, such as order items, track their tickets, and so on.

You choose which app shell to apply to your experience when you create a new experience in the ServiceNow® platform. For more information on how to create a new experience, see *Create an experience for UI Builder*.

You can choose from a number of app shells when creating a new experience.
Agent Workspace and portal app shell descriptions

<table>
<thead>
<tr>
<th>App shell</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Agent Workspace app shell</td>
<td>The Agent Workspace app shell contains the headers and footers for an Agent Workspace. An Agent Workspace includes the tools that agents need to find, research, and resolve issues. The ServiceNow platform provides different Agent Workspaces for different issue types. For example, agents using ITSM Manager Workspace (ITSM) track and resolve IT issues. Agents using Customer Service Management Workspace (CSM) resolve external customer cases, such as sending a piece of computer hardware to fulfill a customer’s request.</td>
</tr>
</tbody>
</table>
Agent Workspace and portal app shell descriptions (continued)

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Portal app shell</td>
<td>The portal app shell contains the header and footer for a portal experience. The portal app shell record is a reference implementation of how the menu, utilities, logo, and login are configured for a portal experience.</td>
</tr>
</tbody>
</table>

**Experience settings for UI Builder**

Learn about the User Interface (UI) Builder experience settings to build your own workspace and custom portal experiences.

By changing the settings of the workspace or portal experience that you're working in, you can affect how your users interact with the experience, how the experience looks, and how users navigate to and from the experience.

Before you can edit the experience settings, you need to be in the correct application scope. If you're in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker (Global), and then select the application scope that you want. For more information about the application scope, see Security and roles.

**Workspace experience settings**

You can change these settings for your workspace experience:

- Modify or add some general settings for your experience. For example, you can change the title, description, and the path of the workspace or portal.

- Apply your organization's branding to all pages in your experience or to a page within your experience.

- Configure your side navigation settings to add pages to the side navigation in your experience.

- Turn on or turn off the notifications for your experience. You can change the global search settings for your experience. For example, you can choose to show or hide the search bar in your experience or change the search source that determines where the search results come from.
Workspace edit experience settings screen

<table>
<thead>
<tr>
<th>General</th>
<th>What are experience settings?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Branding and theming</td>
<td></td>
</tr>
<tr>
<td>Side navigation</td>
<td></td>
</tr>
<tr>
<td>Utilities</td>
<td></td>
</tr>
</tbody>
</table>

These settings allow you to customize your web experience to your needs. You can apply your organization's branding, pick a theme, configure navigation systems, or enable search functionality on any pages you create. Learn more on setting up your experience.

**Portal experience settings**

You can change these settings for your portal experience:

- Modify or add general settings for your experience. For example, you can change the title, the description, and the path of the workspace or portal.
- Apply your organization's branding to all of the pages in your experience or to a page within your experience.
- Set up the navigation and menu settings in the app shell of your portal experience. The app shell, which is the wrapper of the portal contents, is similar to a Google Chrome web page.
- Control whether the global search functionality is visible to the users of your portal experience. For example, you can enable or disable the global search for either your public or private pages.

To learn more about the workspace experience settings, see **UI Builder workspace experience settings**.

To learn more about the portal experience settings, see **UI Builder portal experience settings**.

**UI Builder workspace experience settings**

You can change the User Interface (UI) Builder workspace experience settings to fit your company goals.
By changing the experience settings, you can affect how your users interact with your workspace experience, how your workspace looks, and how users navigate to and around your workspace.

Before you can edit the experience settings, you need to be in the correct application scope. If you’re in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker ( ), and then select the application scope that you want. For more information about the application scope, see Security and roles.

Learn how you can change these workspace experience settings:

• Modify or add the workspace general settings for your workspace experience. For example, you can change the title, the description, and the path of the workspace.

• Work with the workspace branding and theming settings to apply your organization’s branding to all pages in your workspace experience or to a specific page within your workspace experience.

• Change the workspace side navigation settings to add pages to the side navigation in your workspace experience.

• Modify the workspace utility settings to turn on or turn off notifications for your workspace experience. Also, you can change the global search settings for your workspace experience. For example, you can choose to show or hide the search bar in your workspace experience or change the search source that determines where the search results come from.

Experience settings for workspace

<table>
<thead>
<tr>
<th></th>
<th>What are experience settings?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>These settings allow you to customize your web experience to your needs. You can apply your organization’s branding, pick a theme, configure navigation systems, or enable search functionality on any pages you create. Learn more on setting up your experience.</td>
</tr>
</tbody>
</table>

Change the general settings in your workspace experience

Change the general settings for your workspace experience in User Interface (UI) Builder to fit the needs of your organization. For example, you can modify the title, description, and path for your workspace experience.
Before you begin
You need to be in the correct application scope to edit the experience settings. If you're in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker ( ), and then select the application scope that you want. For more information about the application scope, see Security and roles.

Role required: ui_builder_admin

Procedure
1. Navigate to Now Experience Framework > UI Builder.
2. Open a workspace experience or create an experience by selecting Create experience in Platform.
   For more information, see Create an experience.
3. Open or create a page in your workspace experience.
4. To change the title, description, and path of your workspace experience, go to the menu and then click Edit experience settings.
   • The title lets everyone know what the workspace is called. Take care when choosing a name for your workspace.
   • The description lets your users know the details of the workspace.
   • The path must be unique. The path can include digits (0-9), letters (A-Z, a-z), and a few special characters ("-", ".", "_", or "~") with the words separated by a forward slash or hyphen.

5. To edit the workspace record on the Now Platform, navigate to **General > Advanced settings**.

6. Update the record in the platform when you are finished. When you go back to your workspace experience settings in UI Builder, you see the changes that you made to the general settings.

### Change the brand and theme settings in your workspace experience

Change the brand and theme settings for your workspace experience in UI Builder so that your users can see a consistent look and feel across all pages.

**Before you begin**

You need to be in the correct application scope to edit the experience settings. If you’re in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker (Global), and then select the application scope that you want. For more information about the application scope, see **Security and roles**.

Role required: ui_builder_admin

**Procedure**

1. Navigate to **Now Experience Framework > UI Builder**.

2. Open a workspace experience to work in or create an experience by selecting **Create experience in Platform**.
   For more information, see **Create an experience**.

3. Open or create a page in your workspace experience.

4. From the list, select **Edit experience settings**.

5. Make changes to your brand and theme.
   For more information about themes in UI Builder, see **Work with themes**.

<table>
<thead>
<tr>
<th>Action</th>
<th>Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apply a theme</td>
<td>a. Select <strong>Branding and theming</strong>. If themes are available on your instance, select a theme from the list so that you can apply or change the theme for the workspace record on the platform, including</td>
</tr>
</tbody>
</table>
a. To edit the application record, navigate to Branding and theming > Advanced settings. You are now in the Now platform where you can edit the application record.

b. Update the record in the platform when you are finished.

c. To go back to your portal experience, select Open in UI Builder. Refresh UI Builder to see the changes that you made to the branding and theming.

Workspace platform opens in UI Builder.

**Add pages to the side navigation in your workspace experience**

Add primary and secondary pages to your workspace side navigation in User Interface (UI) Builder so that your users can navigate to different pages within your workspace experience.

**Before you begin**

Role required: ui_builder_admin

**About this task**

You can add up to seven pages to your side navigation.

You need to be in the correct application scope to edit the experience settings. If you are in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker (Global), and then select the application scope that you want. For more information about the application scope, see [Security and roles](#).
Procedure

1. Navigate to **Now Experience Framework > UI Builder**.

2. Open a workspace experience to work in or create an experience by selecting **Create experience in Platform**. For more information, see **Create an experience**.

3. Open or create a page in your workspace experience.

4. To change the settings for the entire workspace experience that you are working in, go to the menu and click **Edit experience settings**. You can only change the experience settings in the workspace record in the **Now Platform®**.

5. To add pages to the side navigation in your workspace experience, click **Side navigation**.

6. To go to the Now Platform® to modify the navigation settings in the application record, select **Advanced side navigation settings**.

   **Experience settings for the workspace side navigation**

   **Side navigation**

   Choose up to 7 pages to add to your side navigation. Each page can have an icon and reflect a certain order. Learn more

   ![Advanced side navigation settings](image)

   **a.** Search for the page that you want to add to your side navigation. You can add multiple pages to your workspace side navigation, but only the first seven icons show in the side navigation in the order that you select.

   **b.** If you have more than one page, define the order value of the page in the workspace side navigation.

7. Select **Submit**.

8. Go back to your workspace experience in UI Builder and preview your page to see the side navigation.

   You can preview your page in UI Builder by clicking **Open** in the right corner of the URL field.

**UI Builder portal experience settings**

You can change your UI Builder custom portal experience settings to affect how your users interact with your portal experience.
Use experience settings to change the settings for the custom portal experience that you are working in. These settings affect how your users interact with your portal experience, how your portal looks, and how users navigate to and around your portal.

You need to be in the correct application scope to edit experience settings. If you are in a different scope, the experience settings are read-only. To change your application scope, in the main header, select the application picker, and then select the application scope that you want. For more information about the application scope, see Security and roles.

Learn how to change the following portal experience settings.

• Modify or add portal general settings for your portal experience. Change the title of your portal, the description, and the path of the portal.

• Work with portal branding and theming to apply an existing theme, or create a theme for your portal experience. You use a theme to add your organization's branding to all of the pages in your portal experience or to a specific page within your portal experience.

• Use portal navigation and menu settings to set up the navigation and menu settings in the app shell of your portal experience. The app shell is the wrapper of the portal contents. For example, the app shell can show things like the logo of your company, user preferences, the search icon, the configuration icon, and the user menu. For more information about app shells, see App shells for UI Builder.

• Modify the Portal search settings to show or hide the global search functionality on public or private pages in your portal experience.

---

**Change the general settings in your portal experience**

Change the general settings for your custom portal experience in UI Builder. For example, you can modify the title, description, and path for your portal experience.

**Before you begin**

You need to be in the correct application scope to edit the experience settings. If you're in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker.
( Local ), and then select the application scope that you want. For more information about the application scope, see Security and roles.

Role required: ui_builder_admin

Procedure

1. Navigate to Now Experience Framework > UI Builder.

2. Open a portal experience to work in or create an experience by selecting Create experience in Platform.
   For more information, see Create an experience.

3. Open or create a page in your portal experience.

4. From the menu, click Edit experience settings to change certain settings for the portal experience you are working in.
   You can fully change all the experience settings in the portal record in the Now Platform®.

5. To change the title, description, and the path of the portal experience, click General.
   • The title lets everyone know what the workspace is called. Take care when choosing a name for your portal.
   • The description lets your users know the details of the portal.
   • The path must be unique. The path can include digits (0-9), letters (A-Z, a-z), and a few special characters ("-", ".", "+", "~"), with the words separated by a forward slash or hyphen.

   a. Add a title for your portal experience.
      The title of the portal is required. The title is an important part of the portal settings, as it tells everyone what the portal is. Take care to choose the proper name and naming convention when naming or changing the name of a portal.

   b. Optional: Add a description for your portal experience.
      The description helps the administrators and developers know the details of the portal.

   c. Set the path for your portal experience.
      The path is set based on the name of the page that you created in your portal experience. You can change this path any time. The path is required and must be unique. The path can include digits (0-9), letters (A-Z, a-z), and a few special characters ("-", ".", "+", "~"), with the words separated by a forward slash or hyphen.
6. To edit the portal record on the Now Platform, navigate to **General > Advanced settings**.

7. **Optional:** To change the title, description, and the path of the portal record on the Now Platform, click **Advanced settings**. You must have the proper role assigned to you before you can make these changes.

8. Update the record in the platform when you are finished.

**Results**
When you go back to your portal experience settings in UI Builder, you see the changes that you made to the general settings.

**Change the brand and theme settings in your portal experience**
Change the brand and theme settings for your custom portal experience in UI Builder so that your users can see a consistent look and feel across all pages.

**Before you begin**
You need to be in the correct application scope to edit the experience settings. If you're in a different scope, the experience settings are read-only. To change your application scope, go to the main header, select the application picker (Global), and then select the application scope that you want. For more information about the application scope, see **Security and roles**.

Role required: ui_builder_admin

**Procedure**

1. Navigate to **Now Experience Framework > UI Builder**.

2. Open a portal experience to work in or create an experience by selecting **Create experience in Platform**. For more information, see **Create an experience**.

3. Open or create a page in your portal experience.

4. To change certain settings for the portal experience that you are working in, from the menu, click **Edit experience settings**. You can fully change all the experience settings in the portal record in the Now Platform®.

5. Make changes to your brand and theme.
   For more information about themes in UI Builder, see **Work with themes**.

**Change the navigation and menu settings in your portal experience**

Change the header, footer, and menu settings for your custom portal experience in UI Builder to fit the needs of your organization.

**Before you begin**

Role required: ui_builder_admin

**About this task**

Set up the navigation and menu settings in the app shell of your portal experience. The app shell is the wrapper of the portal contents. For example, the app shell can show things like the logo of your company, user preferences, the search icon, the configuration icon, and the user menu. You can configure this app shell in the Now Platform. For more information about app shells, see [App shells for UI Builder](#).

You need to be in the correct application scope to edit experience settings. If you are in a different scope, the experience settings are read-only. To change your application scope, in the main header, select the application picker ( ), and then select the application scope. For more information about the application scope, see [Security and roles](#).
Procedure

1. Navigate to **Now Experience Framework > UI Builder**.
2. Open a portal experience to work in or create a portal experience by selecting **Create experience in Platform**.
   For more information, see **Create an experience**.
3. Open or create a page in your portal experience.
4. To change certain settings for the portal experience that you are working in, from the menu, click **Edit experience settings**.
   You can fully change all the experience settings in the portal record in the **Now Platform®**.
5. To change the settings for the header, footer, and navigation menu for the app shell of the portal experience you are working in, click **Navigation and menus**.

### Portal experience settings for navigation

</tr>
<tr>
<td></td>
<td><strong>c.</strong> To add a second footer to your portal experience, select <strong>Secondary footer</strong>. A secondary footer includes additional text links, social media elements, and copyright information.</td>
</tr>
</tbody>
</table>

6. Click **Save all changes**.
Show or hide the search settings for your portal experience

Show or hide the global search functionality on the public or private pages for your custom portal experience in UI Builder so that your users can search on the portal.

Before you begin
Role required: ui_builder_admin

You can control whether the global search functionality is visible to users of your portal experience. You can enable or disable the global search for either public or private pages.

You need to be in the correct application scope to edit the experience settings. If you are in a different scope, the experience settings are read-only. To change your application scope, in the main header, select the application picker ( ), and then select the application scope. For more information about the application scope, see Security and roles.

Procedure

1. Navigate to Now Experience Framework > UI Builder.
2. Open a portal experience to work in or create a portal experience by selecting Create experience in Platform.
   For more information, see Create an experience.
3. Open or create a page in your portal experience.
4. From the menu, click Edit experience settings to change certain settings for the portal experience that you are working in.
   You can fully change all of the experience settings in the portal record in the Now Platform®.
5. To show or hide the global search settings for your portal experience, click Search.
Portal search

- General
- Branding and theming
- Navigation and menus

Search

Global search

You can show or hide the search functionality on any pages found in your portal. By default, all pages show search.

Learn more

Public pages

- Enable global search

Private pages

- Enable global search

Advanced settings

<table>
<thead>
<tr>
<th>Action</th>
<th>Step</th>
</tr>
</thead>
<tbody>
<tr>
<td>To enable your search functionality on any public-facing pages in your portal experience.</td>
<td>Navigate to <strong>Public pages &gt; Enable global search.</strong></td>
</tr>
<tr>
<td>To enable your search functionality on the private pages in your portal experience.</td>
<td>Navigate <strong>Private pages &gt; Enable global search.</strong></td>
</tr>
</tbody>
</table>

6. To go to the Now Platform to make changes to the application record on the Now Platform®, click **Advanced settings.**

To enable or disable the search for a page, you must create a separate UX Page property. The UX Page property overrides the global search setting.

**Using UI Builder**

Get a full understanding of everything you can do when creating a page for your workspace or custom portal experience in UI Builder.

**UI Builder quick start**

Quick start for UI Builder

**Using UI Builder resources**

Find information on how to create a fully functioning page in UI Builder.

The following information will help you along your UI Builder journey.
• Work with pages.
• Create a variant of a page
• Work with components
• Work with layouts
• Work with themes
• Work with data resources
• Work with events

Work with pages
Learn what a page is in Now® Experience UI Builder. Understand the building blocks of a page, such as containers and components.

UI Builder quick start
UI Builder quick start video
Create pages in UI Builder as part of a workspace or custom portal experience. Pages consist of containers and components. You build a page using containers and components to guide a user through an experience. For example, you could build a page to manage travel requests for your employees. The page could have components that contain lists of all travel requests submitted and approved. You add buttons that let users add and submit travel requests. Then apply a company theme to your components. The way you build your page is limitless.

Components and containers
Components are the building blocks of your page. Add components to your page to build or customize your workspace or portal experience. For example, add a button component to your page that lets users submit requests.

You can add components to your page from the Toolbox or from the page itself. As you add components to your page, use the Content tree to easily navigate between components.

A container is a type of component that can contain other components. Containers have layout properties applied to them. Change the page layout and visual styling to make it your own experience.
Types of containers

<table>
<thead>
<tr>
<th>Container Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Page</td>
<td>A container that spans a large area. It respects the rules of the app it exists in.</td>
</tr>
<tr>
<td>Container</td>
<td>Add components to a container to create the layout and organizational structure for your page. A page may have multiple containers. Containers can also include containers.</td>
</tr>
<tr>
<td>Modal</td>
<td>Use a modal to create a page type in UI Builder that renders on top of the page. Think of a modal as a pop-over screen that requires action.</td>
</tr>
<tr>
<td>Tabs</td>
<td>Use tabs as a collection of containers that only displays one container at a time.</td>
</tr>
</tbody>
</table>

See Work with components for more information.

**Structure of UI Builder**

UI Builder is separated into the following areas.

- Use the left vertical bar for access to the following in UI Builder.
  - Home screen
  - Page management panel
  - Components
  - Data resources
  - Client state
  - Client scripts
• Utilize the page management panel to create, edit, and manage your pages.

• Work in the main page area to build and modify your pages.
• Go to Page configuration to configure your components, add styling, and set events.

• Use the top bar to access the main menu and Help. Also see the URL, and open your page to preview it. You can also select a domain and set application scope. And finally, click the Save button often to save your page.
Left vertical bar

- Home screen: The landing page for UI Builder includes a list of all of your experiences and links to important documentation.

- Page management panel: Control and manage every aspect of your page. Create pages and variants, edit page settings, and use the content tree to easily manage your page construction.

- Components: See every component available in UI Builder that you can use to build your pages. You can drag components from here onto your page.

- Data resources: Bind data to your components using data resources to dynamically expose your data from tables, records, or other elements on your page. Data resources enable you to reuse your components. See Connect data to your components for more information.

- Client state: Set the parameters for the client state for your page. The client state parameters consist of a name, a type, and an initial value. You can see the preview of the client state parameters.

Page management panel

The page management panel lets you manage all aspects of your pages. You can do the following:

- Create a page.
- Open existing pages in your experience.
- Create a variant of a page.
- View existing variants of a page.
- Edit page settings
• Edit **Required parameters** for a page.
• Edit **Optional parameters** for a page.
• Open a page to preview it in a Web browser.
• If you have the proper role, open a page, variant, variant collection, page definition, or app config in Developer mode.
• Work in the **Content** tree, where you see all of your components in a tree, making it easy to navigate through your page.

**Create page**

Create a page to build a page experience from scratch or from a page template. Build a page one component at a time. If you use one of the pre-defined page templates, you start from a base structure and customize it to meet your needs.

Name your page. Set the path (or keep the default path that is automatically added based on your page name). A default path is added based on your page name. You can also create your own path, but the path must be unique. The **URL preview** shows what the path of your page will be.

The application scope protects applications by identifying and restricting access to application files and data. The application scope defaults to the scope that the user is currently in within the Now Platform®. For more information about application scope, see **Security and roles**.

Use a page template to create a page based on a pre-defined page template, and then customize the page to your needs. You can reference or copy a page template. For more information, see **Page templates**.
Create a page: Advanced settings

Add required parameters to your page. A required parameter is a piece of data that your page requires, such as a sysid, table, or query. Required parameters are useful for components, as they can bind to the value of the required parameter. For example, you can add a table parameter to the URL field, and then bind data to that table. When the table is referenced, it exposes the table data to any components on the page. Required parameters are visible in the URL when you add them to your page. In the following example, a required parameter called table was added. Notice it was appended to the URL.

Add optional parameters to your page. Optional parameters are optional pieces of data that you can add to the URL of your page. Unlike required parameters, optional parameters are always name and value pairs that work no matter what order they’re provided.
Select the **Variant** tab to set the audience and conditions settings for your page. When you create a page, UI Builder also creates a variant of the page for you by default. A page variant is a variation of your page at the same path that lets you target experiences for different audiences using user criteria. For example, a page for managers, and a variant of that page for the manager's direct reports. For more information about creating a variant, see [Create a variant of a page](#).

For more information about audiences, see [Understanding your audiences](#).

**Test values**
Add a test value to your page as a way to bring test data into the page for testing purposes. For example, if you add a table as a required parameter, you could add a test value of incident and bind a data resource to it to bring in test data on the incident for that table.
To get test values to show data, add a data resource, then configure the data resource to bind a record to the test value in the URL. For example, you could add `incident` as a test value. Then add a data resource named **Look Up Record**. In the **Table field**, dynamically bind the `incident` test value to a `context.props.table` table, as shown in the following image.

**View an existing page**
You can work in any page in your experience based on your role settings. To change to a different page, click the list next to page.

**Create a page variant**
A page variant is based on another page and exists at the same path as the page. A variant lets you target different audiences using user criteria. For example, you can create a homepage for agents, and a variant of the page for managers that exists at the same URL. You create a page variant by clicking the **Create** on the page management panel.
You set the audience for each page variant. The audience determines who uses the page variant. For example, if you create a travel request page, create a variant of that page for managers to manage the employee travel requests. You set the audience for the manager page for anyone in the manager role. Employees cannot view that variant. For more information about audiences, see Understanding your audiences.

Page variants are listed under **Variants** in the page management panel. You can change to any variant at any time.

See Create a variant of a page for more information.

**Edit page settings**
Change the settings of your page at any time from the **Menu**. Or, click the three-dot menu to the right of your page name and select **Edit page settings**. You can change the name and path of your page after you create a page.

**Edit required page parameters**
Edit required parameters to your page any time from the three-dot menu next to your page name. A required parameter is a piece of data that your page requires, such as a sysid, table, or query. Required parameters are useful for components, as they can bind to the value of the required parameter. For example, you can add a table parameter to the URL field, and then bind data to that table. When the table is referenced, it exposes the table data to any components on the page. Required parameters are visible in the URL when you add them to your page. In the following example, a required parameter called table was added. Notice it was appended to the URL.
Edit optional parameters
Edit optional parameters to your page any time from the three-dot menu next to your page name. Optional parameters are optional pieces of data that you can add to the URL of your page. Unlike required parameters, optional parameters are always name and value pairs that work no matter what order they’re provided.

Parameters

Optional parameter 1 name  
Enter a name for your optional parameter, like "selectedTabIndex"

Content tree

The content tree in the page management panel is important. It not only shows every container and component on your page, it lets you easily find your components and work with them. The content tree is especially important when you have multiple components on your page. You select the component in your content tree to highlight the component on the page, making it easier to build your page.

When you click a component in the content tree, it highlights the component on your page so you can configure them, add styling, events, data, and so on.

It is important to add a component label when you add a component to your page. The component label is used in the content tree to apply labels and IDs to each component in the content tree. You can identify the components much easier in the content tree when they are labeled. Use the pencil icon in the configuration panel to add or edit a component label.
Main page area
The main page area of UI Builder is where you perform the work when building your pages. It is the largest area of UI Builder. You add your containers and components here by either clicking the + button, or dragging components from the Component section to the page.

Configuration panel
Use the configuration panel to configure your components, add styling to your components, set up event handlers for components, and set the layout of a container.

- Select the Config tab to configure components. Each component has different configuration options that let you control the necessary parts of the component. For example, a button component is simple, and you can only configure how it looks, labels, and some properties. A list component is more complicated. You change dozens of list parameters.
Select the Styles tab in the configuration panel to add styling to a component. You can use standards-based Cascading Style Sheets (CSS) to change the visual style of a component. For example, add or change a background color, a border, or any other CSS style.
See Add styling to your component for more information.

• Select the Events tab to configure events in to add actions to your components, pages, data resources, and declarative actions. When you add components to your page, they are not configured to perform any action. For example, a button component is static and does not do anything until you bind an event action to it, such as deleting a record.

![Button 1](image)

See Work with events for more information.

• Layouts. Layouts govern what and how slots are available in a container on a page. A slot is a section of the page where components exist. When you create a page, you configure how you want the layout designed. Decide how many slots are included and how they are arranged. Once you add a component to a container, you can configure the layout systems in more advanced ways. For example, you can choose to have your content displayed as Flex or Grid. Flex lets you set the direction of the component layout, like up, down, or left right. You can also justify the content, align items, and set the height, width, margins, and padding of your content. CSS grid is the most powerful layout system. CSS Grid is built on top of a two-dimensional grid that gives you power over how you create your pages.
Open a page to preview it
Preview a page to see what the page looks like as a web page. Preview a page to test how your page looks and works as you build it. For example, say you add a Delete record button that opens a modal. The modal asks a user to confirm a deletion. You could open the page to ensure that the button and modal work the way you want them to.

Developer editing
From the Menu, edit the page as a developer on the platform. This option is dependent if you have the proper role as a developer and takes you out of UI Builder. This option lets you change the platform-level details of your page.

See Work with layouts for more information.
Create a page in UI Builder

Create a page in Now® Experience UI Builder for a portal, workspace, or custom application so that you can build a web experience for your users.

Before you begin
Role required: ui_builder_admin

About this task
A page has a collection of components that make up a workspace, portal, or custom application user interface (UI).
Procedure

1. Open UI Builder in any of the following ways.

<table>
<thead>
<tr>
<th>To open UI Builder from the following locations</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Now Experience Framework</td>
<td>a. Navigate to <strong>Now Experience Framework &gt; UI Builder.</strong></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>To open UI Builder from the following locations</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Admin panel of a specific experience</strong></td>
<td>b. Click an experience to work in, or create a new experience by selecting <strong>Create experience in Platform</strong>. For more information about creating an experience, see <strong>Create an experience</strong>.</td>
</tr>
</tbody>
</table>
| **From CSM Configurable Workspace**              | a. Navigate to **Experiences** and select your experience.  
|                                                  | b. Open the record in the **Admin panel**.  
|                                                  | c. Click **Open in UI Builder**.  
|                                                  | a. Navigate to **Workspace Experience > Workspaces > CSM Configurable Workspace**.  
|                                                  | b. Click the **User Menu** in CSM Configurable Workspace.  
|                                                  | c. Click **Edit page** to edit the CSM Configurable Workspace in UI Builder. |
To open UI Builder from the following locations

<table>
<thead>
<tr>
<th>From CSM Configurable Workspace</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. Navigate to <strong>Workspace Experience</strong>  &gt; <strong>Workspaces</strong> &gt; <strong>CSM Configurable Workspace</strong>.</td>
<td></td>
</tr>
<tr>
<td>b. Click the <strong>User Menu</strong> in CSM Configurable Workspace.</td>
<td></td>
</tr>
<tr>
<td>c. Click <strong>Configure Workspace</strong>.</td>
<td></td>
</tr>
<tr>
<td>d. Click <strong>Open in UI Builder</strong>.</td>
<td></td>
</tr>
</tbody>
</table>

2. Click an experience to open it, or create a new experience by selecting **Create experience in Platform**. For more information, see Create an experience.

3. Create a blank page, or use one of the included page templates to get you up and running quicker.

<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a blank page</td>
<td>a. Select <strong>Menu</strong> and select + <strong>Create page</strong>.</td>
</tr>
<tr>
<td></td>
<td>b. On the Create a page screen, in <strong>Name of page</strong>, enter the name of your new page.</td>
</tr>
<tr>
<td></td>
<td>c. In the <strong>Path</strong> field, specify a path for your page. A default path is added based on your page name. You can also create your own path. The path is required and must be unique. The path can include digits (0-9), letters (A-Z, a-z), and a few special characters (&quot;_&quot;, &quot;.&quot;, &quot;~&quot;, &quot;&quot;), with the words separated by a forward slash or hyphen. The <strong>URL preview</strong> shows what the path of your page will be.</td>
</tr>
</tbody>
</table>
To do this task | Do this
--- | ---
Create a page |
First, let’s set up this page.

Note: The application scope defaults to the scope that the user is currently in within the Now Platform®. For more information about the application scope, see Security and roles in UI Builder.

d. Select **Create** to create your page.

When creating a page, you can set advanced settings such as required and optional parameters, as well as variant settings.

a. Select **Add required parameters** to add any required parameters to your page URL.
   A required parameter is a piece of data that your page requires, such as a sys_id, table, or query. Required parameters are useful for components, because they can bind to the value of the required parameter.

For more information, see **Work with pages**.

b. Select **Add optional parameters** to add any optional pieces of data that you want to add to the URL of your page.
   Unlike required parameters, optional parameters are always name and value pairs that work no matter what order that they are provided in.

For more information, see **Work with pages**.
To do this task | Do this
---|---
c. Click the required or optional parameter in the URL, and in **Test values** type a value, such as `incident`.
You add a test value to your page to populate data into the page as a way to test it. For example, if you add a table as a required parameter, you could add a test value of `incident` to bring in test data on the incident for that table.

d. Select the **Variant** tab to set the audience and conditions settings for your page.
When you create a page, UI Builder also creates a variant of the page for you by default. A page variant is a variation of your page at the same path that lets you target experiences for different audiences using user criteria. For example, a page for managers, and a variant of that page for the manager's direct reports. For more information about creating a variant, see **Create a variant of a page**
To do this task | Do this
--- | ---
| Page | Variant |
Visibility |
Audiences |
You can target specific audiences with specific content. Audiences are based on user criteria or roles. |
Add audience |
Conditions |
You can adjust when the page will display. |
Set conditions |

For more information about audiences, see Understanding your audiences.

e. Click **Done**.

Use a page template if you want to create a page based on a pre-defined page template. You can customize the page to your needs. When using a template, either reference the template and its data, or copy the contents of the page template. When you reference a page template, your page automatically updates when you upgrade to a new release. If you copy the page template, your page will not update after upgrade. For more information, see Page templates.

a. Select **Menu** and select + Create page.

b. On the Create a page screen, in **Name of page**, enter the name of your new page.

c. In the **Path** field, specify a path for your page. A default path is added based on your page name. You can also create your own path. The path is required and must be unique. The path can include digits (0-9), letters (A-Z, a-z), and a few special characters ("_", ".", "~", ";"), with the words separated by a forward slash or hyphen.

**d.** Select the **Variant** tab to set the audience and conditions settings for your variant page. When you create a page, UI Builder also creates a variant of the page for you by default. A page variant is a variation of your page at the same path that lets you target experiences for different audiences using user criteria. For example, a page for managers, and a variant of that page for the manager's direct reports.

For more information about variants, see Create a page variant.

**e.** Ensure that the **Active** check box is selected to make this page active.

**f.** Select **Done**.

---

**Edit a page**

Edit a page to change the page settings, components, layouts, styles, and data resources.

**Before you begin**

Role required: ui_builder_admin
Procedure

1. Navigate to **Now Experience Framework > UI Builder**.

2. Open an experience to work in. Or, create a new experience by selecting **Create experience in Platform**. See **Create an experience** for more information.

3. Open the page you want to edit.

4. From the **Menu**, select **Edit page settings** to change the name and path of your page. This is useful if you decide the name or path should be changed after you create the page. If your page is in a different application scope, you can choose to edit it in the original scope.

5. **Optional**: You can also change the settings of your page by clicking the three-dot drop-down menu to the right of your page name in the page management panel and selecting **Edit page settings**.

6. From the **Menu**, select **Edit variant settings** to change the settings for any page variants that you have. You can change the name of the variant, change the page template, or change the application scope. You may need to change these settings because the variant was created with the wrong application scope. You may also want to change the page template if the wrong template was incorrectly chosen when the variant was created. Or, you may just want to change the name of the variant.
7. From the Menu, select **Edit experience settings** to change the settings for the entire workspace or portal experience you are working in. See **Experience settings** for more information on both workspace and portal experience settings.

8. Click **Menu > Developer** to edit page and variant settings, page definitions, and app configuration settings on the ServiceNow platform as a developer. This is useful when you need to make changes to the application record itself.

**Test values**

Add test values to your URL as a way to bring test data into a page.

Use test values to provide values for required and optional URL parameters as a way to test your page with actual data.

Test values are important because you can use them to simulate how your page behaves when the page gets its required or optional parameters from the URL. A UI Builder URL is not the same as the URL when you preview your page. So, UI Builder needs a way to simulate what happens to the page during different states of the preview URL.

For example, say that you are building a record page that displays a form for a single record. For the record page to load, the page must have a `<table>` and `<sysId>` in the URL so that it can get and display the proper record. In UI Builder, you must supply test values for the table and sysId so that you can see how the page will look when you preview the page.
To get test values to show data, add a data resource, then configure the data resource to bind a record to the test value in the URL. For example, you could add `incident` as a test value.

Then add a data resource named **Look Up Record**. In the **Table field**, dynamically bind the incident test value to a `context.props.table` table, as shown in the following image.
Page templates

Use page templates to reuse a page definition, such as record or list page, for pages in your workspace or portal.

Before you begin
Role required: ui_builder_admin

About this task
Use a page template to create a page based on a pre-defined page template. Customize the page to your needs. You can reference or copy a page template.

Procedure
1. Navigate to Now Experience Framework > UI Builder.
2. Open an experience to work in. Or, create a new experience by selecting Create experience in Platform. See Create an experience for more information.
3. Create a page using a page template.

<td></td>
</tr>
<tr>
<td>h. Click <strong>Add optional parameters</strong> to add any optional pieces of data to your variant that you want to add to the URL of your variant page. Unlike required parameters, optional parameters are always name and value pairs that work no matter what order they're provided.</td>
<td></td>
</tr>
</tbody>
</table>
To do this task | Do the following
---|---

See [Work with pages](#) for more information.

i. **Optional**: Click the required or optional parameter in the URL, and in **Test values** type a value, such as `incident`. You add a test value to your page to populate data into the page as a way to test it. For example, if you add a table as a required parameter, you could add a test value of `incident` to bring in test data on the incident for that table.

For more information on test values, see **Test values**.

j. Click the **Variant** tab to set the audience and conditions settings for your variant page. When you create a page, UI Builder also creates a variant of the page for you by default. A page variant is a version of your page that lets you target experiences for different audiences using user criteria. For example, you can create a homepage for agents, and a variant for managers at the same URL.
To do this task | Do the following
--- | ---
Click Add audience to set the audiences for your variant to fit a specific role based on one or more criteria.
Select the Active check box to make this page active.
Click Done to create your page.

Create a variant of a page
A page variant in Now® Experience UI Builder is a variation of a page that exists at the same path that targets different audiences using user criteria.
Before you begin
Role required: ui_builder_admin

About this task
Learn how to create a page variant in UI Builder. A page variant is based on your page with content targeted for a different audience. For example, you can create a homepage for agents, and a variant of that page for managers of those agents. The variant exists at the same URL.

Procedure
1. Navigate to Now Experience Framework > UI Builder.
2. Open an experience to work in. Or, create a new experience by selecting Create experience in Platform. See Create an experience for more information.
3. Create or open a page.
4. To create a page variant, you can create it from scratch, or use a page template.

<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. Create a variant from scratch</td>
<td>a. Select Menu and select Create variant. Alternatively, you can click + Create next to Variants on the page as shown in the following image.</td>
</tr>
<tr>
<td>b. Create a variant from scratch</td>
<td>b. On the Create a variant screen, in Variant name, enter the name of your variant. The name can be similar to your page name, or what ever you want it to be.</td>
</tr>
<tr>
<td>c. Create a variant from scratch</td>
<td>c. Select Create to create your variant.</td>
</tr>
</tbody>
</table>

Note: The application scope defaults to the scope that the user is currently in within the Now Platform®. For more information about application scope, see Security and roles in UI Builder.
To do this task | Do the following
--- | ---
 | 
page shows different content based on the au­
dience assigned to the page.

For more information about audiences, see Un­
derstanding your audiences.

b. Select **Set conditions** to set criteria that deter­
mines when your page variant displays to users.

**Edit conditions**

By setting these conditions, you are adding additional criteria
to determine when this page will display

**Variant conditions**

e.g. `table=incident^sys_id!=-1` will only show this variant if the
table field is incident, and the sys_id field is not -1

**Order**

100

**Application scope**

Global

For more information on how to edit these con­
ditions, see **Edit conditions**.

c. Add an encoded query string in the **Variant
conditions** field. The query string can be some­
thing like

`table=incident^sys_id!=-1`

This query string only shows this variant if the ta­
ble field is incident, and the sys_id field is not -1.
For more information on encoded query strings, see **Encoded query strings**.

d. Add an order for the condition in the **Order**
field. You may want certain conditions to have
<table>
<thead>

<table>
<thead>
<tr>
<th>To do this task</th>
<th>Do the following</th>
</tr>
</thead>
</table>

**d.** Choose to either reference the template and its data, or copy the contents of the page template. When you reference a page template, your variant automatically updates when you upgrade to a new release. If you copy the page template, your variant does not update after you upgrade.

**Note:** The application scope defaults to the scope that the user is currently within the Now Platform®. For more information about application scope, see Security and roles in UI Builder.

**e.** Select **Create** to create your variant.

**a.** Select **Add audience** to set the audience settings for your variant page to fit a specific role based on one or more criteria. The audience is important because it lets you assign your page variant to a specific role, group, and so on. The page shows different content based on the audience assigned to the page.

For more information about audiences, see Understanding your audiences.
To do this task | Do the following
---|---

**b.** Select **Set conditions** to set criteria that determines when your page variant displays to users.

**Edit conditions**

By setting these conditions, you are adding additional criteria to determine when this page will display

**Variant conditions**

* e.g. `table=incident^sys_id!=-1` will only show this variant if the `table` field is `incident`, and the `sys_id` field is not `-1`

**Order**

100

**Application scope**

Global

For more information on how to edit these conditions, see **Edit conditions**.

**c.** Add an encoded query string in the **Variant conditions** field. The query string can be something like

```
table=incident^sys_id!=-1
```

This query string only shows this variant if the `table` field is `incident`, and the `sys_id` field is not `-1`. For more information on encoded query strings, see **Encoded query strings**.

**d.** Add an order for the condition in the **Order** field. You may want certain conditions to have a higher priority than others. The lower the number, the higher the priority.

**e.** Select **Done**.

**Edit conditions**

A page variant has the same URL as a page. Edit the UI Builder page variant conditions to add additional criteria to determine when the page variant displays to users.
Before you begin
Role required: ui_builder_admin

About this task
You can use audience settings to set who sees a page variant. But you also edit the conditions to determine when a page variant is shown. The conditions are based on setting an order, and adding a query string that sets the criteria that must be met for the page variant to display. If you have multiple page variants that all have the same conditions, then the variants will go by the order setting. The following task shows how to set the variant conditions and order.

Procedure
1. Navigate to Now Experience Framework > UI Builder.
2. Open an experience to work in. Or, create a new experience by selecting Create experience in Platform. See Create an experience for more information.
3. Create or open a page variant.
4. In the page management panel, to the right of the variant, select Edit conditions to set criteria that determines when your page variant displays to users.

   Edit conditions

   By setting these conditions, you are adding additional criteria to determine when this page will display

   Variant conditions

   e.g. table=incident^sys_id!=-1 will only show this variant if the table field is incident, and the sys_id field is not -1

   Order: 100

   Application scope: Global

5. Add an encoded query string in the Variant conditions field. The query string can be something like table=incident^sys_id!=-1. This query string will only show this variant if the table field is incident, and the sys_id field is not -1. For more information on encoded query strings, see Encoded query strings.
6. Add an order for the condition in the **Order** field. You may want certain conditions to have a higher priority than others. The lower the number, the higher the priority.

7. Click **Save**.

**Work with components**

Learn what a component is in UI Builder. Also, see how components work within UI Builder.

Components are the base elements of your page. Components range from core elements like buttons and labels to more complex experience components like lists and forms.

You can add these components to your page to build or customize your workspace or portal experience. For example, adding an **Activity stream** component to your page that lets users see their travel request activity.

You can add components to your page in the following ways.
### Ways to add a component to a page

<table>
<thead>
<tr>
<th>Location</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>From the <strong>Components</strong> list in the far left column in UI Builder</td>
<td><img src="image1.png" alt="Image of UI Builder" /></td>
</tr>
<tr>
<td>Directly from a page in UI Builder</td>
<td><img src="image2.png" alt="Image of UI Builder" /></td>
</tr>
<tr>
<td>From the <strong>Content</strong> tree in UI Builder</td>
<td>Selecting a component in the content tree highlights the component.</td>
</tr>
</tbody>
</table>
### Ways to add a component to a page (continued)

<table>
<thead>
<tr>
<th>Location</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Selecting the component in the content tree also exposes the <strong>Config</strong> panel where you configure the component properties.</td>
</tr>
</tbody>
</table>

![Component Configuration Example](image-url)
Ways to add a component to a page (continued)

<table>
<thead>
<tr>
<th>Location</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>From the floating menu above the page in UI Builder</td>
<td><img src="image_url" alt="Image" /></td>
</tr>
</tbody>
</table>

**Containers**
A container is a type of component that you add to your page first. You then add other components to a container to build or customize your page. Think of a container as a defined part of the screen where you add components like lists and headings. You can have as many containers on a page as you want, with as many containers within containers, with as many components in the containers. As you add containers to your page, use the `Content` tree to easily navigate between the containers.
Configure components
There are three ways to configure a component in the configuration panel.

- Configure the component properties.
- Add CSS style overrides.
- Set up event handlers for the components.

Config tab. Component authors configure components to expose the appropriate properties required to set up their components. Component properties vary based on each component. Component configuration can be simple, as is the case with simple elements like buttons, headings, and labels. Experience components like lists and forms require significant configuration.

For more information about configuring components, see Now® Experience Components.

Styles tab. You can change the Cascading Style Sheets (CSS) styles for individual components. Change color borders, font size, and so on.

Events tab. Configure page-level and variant-level event mappings. Also add dispatched events and handled events for your variant. The more complex, experience components rely heavily on dynamic data that is provided by a data resource. Binding dynamic data to a component is an important feature.

You dynamically expose data from tables, records, or other elements on your page. Exposing data enables you to reuse your components. Also, you can point to the configuration fields to see icons data or scripting options for each field.

For each property in the component configuration panel, you can choose from the following options.

- Static: Use data from a list, or enter your own data. The data doesn't connect to an external data source.
- Dynamic data binding: A way to bind a component property to a data resource, page property, or client state.
- Script: Enter JavaScript code to populate a property value.
Component ID
Use the component ID when you add a script or bind data to the component as a way to reference the component. A component ID is automatically created and is based on the component label when you add a component to a page. You can change the component ID to anything you want, as long as it is unique. Click the pencil icon in the Config panel to see the component ID.

Component details

Component label
- Button 1

Component ID
- button_1

Apply Cancel

Component visibility
Select the eye icon in the Config panel to set component visibility. Component visibility is based on a property of the component itself, not who is viewing it. You could show or hide a component based on conditions. For example, hiding an image if it has a broken link.

Set the Test value to test what happens when the visibility is set to true, false, or none.

Test value
- None
- true
- false
- None

You can set the visibility based on dynamic data binding, or by editing a scripted property value.
Add and configure components

Learn how to add components to your page in Now® Experience UI Builder. A page is built by adding components.

Before you begin
Role required: ui_builder_admin

About this task
Learn how to add a component to a page. Once you add a component to a page, you must configure the component. For more information about configuring components, see Components.

Procedure
1. Open UI Builder in any of the following ways.

<table>
<thead>
<tr>
<th>To open UI Builder from the following locations</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>b. Click an experience to work in. Or, create a new experience by select-</td>
</tr>
</tbody>
</table>
To open UI Builder from the following locations | Do this
--- | ---
**Admin panel of a specific experience** | ing **Create experience in Platform**. See **Create an experience** for more information.

| | a. Navigate to **Experiences** and select your experience.
b. Open the record in the **Admin panel**.
c. Click **Open in UI Builder**.

| From CSM Configurable Workspace | a. Navigate to **Workspace Experience > Workspaces > CSM Configurable Workspace**.
b. Click the **User Menu** in CSM Configurable Workspace.
c. Click **Edit page** to edit the CSM Configurable Workspace in UI Builder.

| From CSM Configurable Workspace | a. Navigate to **Workspace Experience > Workspaces > CSM Configurable Workspace**.
b. Click the **User Menu** in CSM Configurable Workspace.
c. Click **Configure Workspace**.
To open UI Builder from the following locations

<table>
<thead>
<tr>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="UI Builder menu" /></td>
</tr>
</tbody>
</table>

d. Click **Open in UI Builder**.

2. Open or create a page. If you open an existing page, ensure you are in the same scope as the original page. If not, change the scope before you start editing the page. Application scoping protects applications by identifying and restricting access to application files and data. Administrators set the scope to specify what parts of an application are accessible to other applications. Application scope protects data and application files. See [Security and roles](#) for more information on application scope.

3. Change the layout of the page or containers as follows. See [Work with layouts](#) for more information.

<table>
<thead>
<tr>
<th>Are you working in an existing page, or a new page?</th>
<th>Then change the layout procedure as follows:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Working in an existing page</strong></td>
<td>Change the layout to add a component to a specific location. For example, say that the page already has a three-column container. Each column has a data visualization component. But, you must add another data visualization component. You can highlight the container and change the layout to four columns. Then, you can add the new data visualization component to the fourth column.</td>
</tr>
</tbody>
</table>
### Are you working in an existing page, or a new page?

<table>
<thead>
<tr>
<th>Then change the layout procedure as follows:</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Layout Procedure" /></td>
</tr>
</tbody>
</table>

**a.** Select the container on your page for which you want to change the layout. Or, you can select the container in the content tree to the left of the main page area. The content tree is often easier to use. When the page structure is in the structured tree, you can more easily find the container you want to change.

**b.** Select the **Layout** tab and select the layout you want to change it.
Are you working in an existing page, or a new page?

Then change the layout procedure as follows:

to. For example, say that the container has a three-column layout. You can change the layout to a four-column layout. Then, you can add a component in that fourth column in your container.

c. Select **Save** often as you work.

d. Select **Open** to see a preview of what it looks like as a web page.

Start by setting the layout you want for the page. For example, you can set your page to have two slots or columns. Then, you can add containers to each slot and change the layout for each container. You can also set the layout at the container level after you add containers to your page.

a. Select the **Body** of your page in the content tree to the left of the main page area. The content tree is a graphical look at how your page
Are you working in an existing page, or a new page?

Then change the layout procedure as follows:

construction. **Body** is the top page-level.

b. Select the **Layout** tab in the page configuration on the left. Layouts govern what slots are available on a page. Layouts also decide how to position slots, and what CSS rules apply to them. You can choose to have your page divided into columns, rows, or any custom design you want. You can also set the layout for a container.

c. Select **Save** often as you work.
Are you working in an existing page, or a new page?

<table>
<thead>
<tr>
<th>Then change the layout procedure as follows:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
<tr>
<td>d. Select <strong>Open</strong> to see a preview of what it looks like as a web page.</td>
</tr>
</tbody>
</table>

4. Add components to your page. UI Builder comes with a library of components to choose from. You add components as the building blocks of your page. For example, you can add a heading, data visualizations, and so on. The following table shows you the different ways you can add a component to a page.

<table>
<thead>
<tr>
<th>To add a component</th>
<th>Do the following</th>
</tr>
</thead>
<tbody>
<tr>
<td>From the component list</td>
<td>Select the <strong>Components</strong> icon in the left column of UI Builder. Drag a component from the component list onto your page.</td>
</tr>
<tr>
<td>Directly from your page</td>
<td>From your page, select + and choose a component from the list. You can search for a component or scroll through the list.</td>
</tr>
<tr>
<td>To add a component</td>
<td>Do the following</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>Floating menu above page</td>
<td>Select the floating menu above your component.</td>
</tr>
<tr>
<td></td>
<td>• Select <strong>Add component</strong>.</td>
</tr>
<tr>
<td></td>
<td>• Choose a component from the component list.</td>
</tr>
<tr>
<td>To add a component</td>
<td>Do the following</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>You can add a component from the content tree in the following two ways.</td>
<td></td>
</tr>
<tr>
<td>• Select <strong>Add component</strong> beneath the container in the content tree. Then choose a component from the component list.</td>
<td></td>
</tr>
<tr>
<td>• Select <strong>Add</strong> to the right of the content tree, then select Component. Then choose a component from the component list.</td>
<td></td>
</tr>
</tbody>
</table>

5. Now configure the properties of the components that you just added. Configuring components means to customize them to your needs.

For more information about configuring components, see [Now® Experience Components](#).

a. Select the component you want to configure.

b. Select the **Config** tab from configuration in UI Builder.
c. Customize the component properties for the component. For example, you could add a name for a button component. Some components, like data visualizations, require a data source before you can configure the properties. Each component has different configuration properties based on the requirements and options for each component. For example, the Button component configuration is simple, while a List component requires more configuration.

For more information about configuring components, see Now® ExperienceComponents.

6. Optional: Select the Events tab to add an event handler to your component. You add an event handler to add actions to components on your page. For example, a button component is static and does not do anything until you bind an event action to it, such as saving a record. Some components do not have an event action applied to them, such as a heading component. But many components require you to map an event to your component to actually make it perform an action. See Bind an event to a component for more information on how to add event handlers to your component.

7. Optional: You can override any styles for a component by adding CSS styling under the Styles tab. For more information, see Add styling to a component.

Note: Style changes only affect a single component at a time. To change the visual style of all components in your experience, you must apply a theme to your experience. For more information, see Apply a theme to your experience.

8. Optional: Add additional containers to your page to display your components in an organized way. For example, one container could have a heading component. Another container below it could include a list component, a button component, and so on.

a. Select the + at the top of your container to add a container component before the existing component. Select the + at the bottom of a component to insert a container component after it.

b. Drag a container component from the Components list to your existing container on the page. Hold over the top line of the container to insert the new container before the existing container. Hold the container over the bottom line of the existing container to add it after.

9. Optional: Add more components to your page. Select the + on the top or bottom of components on the page. The + changes to + Add.
a. Select the + at the top of your component to add a component before the existing component. Select the + at the bottom of a component to insert a component after it.

b. Drag a component from the component list to insert the component before or after an existing component.

10. Optional: To make a modal appear when you select a component such as a button, you must add the modal to the component first. A modal is a confirmation pop-up that appears when you click the component. For example, if you add a button component that deletes a record, you add a modal to ask the user to confirm they want to delete the record. See Modals in Now Experience UI Builder for more information.

11. Select Save often on your page as you work.

12. Select Open to preview your page.

What to do next
You have added and configured components on your page. See work with data resources for more information. A data resource in UI Builder is the data that a page fetches to display content in components. Components use data resources as a way to reuse data and configurations across different experiences, and make the components dynamic on a page.

Add styling to a component
Set CSS styles for a component to change its default appearance.

Before you begin
Role required: ui_builder_admin

About this task
This task describes how to add styles to the wrapper containing your component, which is generally recommended instead of applying styles to the component directly. Make sure that the component whose styles you want to define is placed within a container component to put the component in a wrapper. Your component's wrapper is one level higher than the component in the Content hierarchy and is labeled by default as Main.
To add styling to an entire page, you can use standards-based CSS in the wrapper for the page. To add styling to your entire experience, you must Apply a theme to your experience.

Procedure

1. Navigate to Now Experience Framework > UI Builder.
2. Select an experience from the list, or select + Create experience in Platform to create a new experience and add it to the list. After selecting the experience you want to build, the UI Builder environment appears.
3. If you haven’t created a page for your experience, follow the steps to Create a page in UI Builder and Add and configure components.

   Note: Place your component in a container before adding styles to the component.

Then, in the Content panel, select the wrapper holding the component that you want to add styling to. Your component’s wrapper is one level higher than the component in the Content hierarchy and is labeled by default as Main. The Main Styles configuration panel appears.

4. In the CSS Styles window, enter standards-based CSS properties and values. The following CSS properties are the most commonly used to apply styles for components within containers:

   - background-color
   - background-image
   - border-style
   - border-width
   - border-color
   - border-radius
   - box-shadow
   - height
   - min-height
   - max-height
   - margin
   - overflow
   - padding
   - width
• min-width
• max-width
• z-index

**Important:** Some components contain built-in styling configurations that you cannot override with CSS in UI Builder. To override these style configurations, you must Apply a theme to your experience.

5. In the main header, select **Save** to save your changes.

---

**Work with viewports**

Viewports are specialized components that enable you to extend your experience without needing to own the parent page in Now® Experience UI Builder. You can work with viewports in three ways. You can add a viewport component or a viewport-enabled tab to a page, or add a viewport to the Contextual sidebar component.

Add a viewport component to your page to create separate content even if you do not own the content of the page itself. Create sub-pages, specify audiences, or customize content with different data, routes, and screens. For more information about viewport components, see **Viewport component**.

You can replace Tabs components with Viewport-enabled tabs as a way to display third-party custom data, assign audiences, and create variants. For more information about viewport-enabled tabs, see **Replace a tab with a viewport-enabled tab**.

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Adding viewports within a Contextual sidebar component is unique because you design the viewport in the Edit content mode of UI Builder and not on the page itself.

Edit tabs in a Contextual sidebar component as you would on a page using the Config panel. The main difference is, when you are in Edit content mode of a tab, the page management area changes to Tab management.

Select the menu icon to edit your tab settings, or change the required or optional parameters. For more information about using viewports in a Contextual sidebar component, see Add a viewport to a contextual sidebar component.

Add a Tabs component

Use the Tabs component to add tabs inline on your page. Each tab has its own container. Add components and tabs within a Tabs component on your page. You can move tabs in the Config pane to reorder them on the page.

Before you begin
Role required: admin

Procedure
1. Navigate to Now Experience Framework > UI Builder.
2. Open an experience to work in. Or, create a new experience by selecting Create experience in Platform. See Create an experience for UI Builder for more information.
3. Create or open a page.
4. Add a Tabs component to your page.

For more information on how to add a component to a page, see Add and configure components.
5. Click the **Edit settings** icon to add a tab label and icon to your Tabs component.

**Add label and icon to Tabs component**

*Edit settings for Tab 1*

<table>
<thead>
<tr>
<th>Tab label</th>
<th>Tab 1</th>
</tr>
</thead>
</table>

| Icon (Optional) | Add Item Above Fill |

6. Add a component to your tab, such as a list, button, or heading. The following example shows a Heading component, labeled **Tab 1 heading**.

7. You can also add additional tabs within a Tabs component. Click (+) in the Tabs configuration panel.
8. Add a label for your second tab. The following example shows Tab 2. Click the down arrow to choose an icon for the tab, then click Create when finished.

Add tab label and icon to Tab 2

Add a tab

Set this tab up with a label and icon. The icon is optional.

Tab label: 
Tab 2

Icon (Optional)

No icon

Search

- Add Item Above Fill
- Add Item Above Outline
- Add Item Below Fill
- Add Item Below Outline
- Add Item Left Fill
- Add Item Left Outline
- Add Item Right Fill
- Add Item Right Outline

9. Click the Config panel to configure the tabs.
a. From the Config panel, drag the tabs to reorder them. The tab reorder will then be reflected on the page.

Reorder tabs

<table>
<thead>
<tr>
<th>Tabs</th>
<th>Add</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tab 1</td>
<td></td>
</tr>
<tr>
<td>Tab 2</td>
<td></td>
</tr>
</tbody>
</table>

Default ⌁

- Span tab labels full width of tabs container ⌁
- Hide all tab labels ⌁

b. Click the Default down arrow to choose which tab opens by default when the page loads.

Set default tab

<table>
<thead>
<tr>
<th>Tabs</th>
<th>Add</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tab 1</td>
<td></td>
</tr>
<tr>
<td>Tab 2</td>
<td></td>
</tr>
</tbody>
</table>

Default ⌁

- Span tab labels full width of tabs container ⌁
- Hide all tab labels ⌁
c. Choose where the tab labels appear on the page, and whether to hide tab labels so you only see the icons.

Set tab labels full width, or hide tab labels.

- Span tab labels full width of tabs container
- Hide all tab labels

Results
Your page shows the two tabs you created. Click each tab to further configure them, add styling, or add an event handler. For more information on styling, see Add styling to a component. For more information on adding an event handler, see Events in UI Builder.

Replace a tab with a viewport-enabled tab
Convert a tab on a page to a viewport-enabled tab. Use viewport-enabled tabs to display third-party custom data, assign audiences, and create variants.

Before you begin
Role required: admin

About this task
Replace your tab or tabs with viewport-enabled tabs.

Note:
Replacing a tab with a viewport-enabled tab is a permanent and one-way process. You lose any existing tab content and must recreate the viewport tab content.
Procedure

1. Navigate to Now Experience Framework > UI Builder.
2. Open an experience to work in. Or, create a new experience by selecting Create experience in Platform. See Create an experience for UI Builder for more information.
3. Create or open a page with existing tabs, or add a Tabs component to your page.

   Tabs component
   
   Components
   
   ![Component image]
   
   For more information on how to add a Tabs component to a page, see Add a Tabs component.

4. Click the three-dot icon ( ⋮ ) and select Replace with viewport tabs.

Note:
Replacing a tab with a viewport-enabled tab is a permanent and one-way process. You lose any existing tab content and must recreate the viewport tab content.

**Viewport tab**

<table>
<thead>
<tr>
<th>Tabs 1</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>ID: viewport_nrj</td>
<td></td>
</tr>
</tbody>
</table>

[Image of Viewport tab configuration]

5. Click **+ Add** in the Config panel to add a viewport-enabled tab.

For more information on viewport components, see [Viewport component](#).

6. From **Create a tab**, add the following information:

   a. In the **Name of tab** field, type a name for your viewport-enabled tab. For example, **Viewport tab**.

   b. Keep the default path, or change it to your preference.

   c. Choose a **page template** to start with a pre-defined template.

   d. Enter an order for the tab. The lower the number, the higher the priority.

   e. Choose an **icon** to represent the viewport-enabled tab.
f. Click **Create** to create the viewport-enabled tab.

g. In the Success! screen, click the **Variant** tab to add an audience for the viewport-enabled tab. Setting an audience lets you define who can see the viewport-enabled tab. For more information about audiences, see **Understanding your audiences**.
**Viewport-enabled tab audience**

**Success!**

Your tab has been created and we have created the first tab variant for you. Variants render different content for different users at the tab’s URL path.

Apply these additional settings now or later.

<table>
<thead>
<tr>
<th>Tab</th>
<th>Variant</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Visibility</th>
</tr>
</thead>
</table>

**Audiences**
You can target specific audiences with specific content. Audiences are based on user criteria or roles.

**Conditions**
You can adjust when this tab will display.

| order: 0 |

**Access controls**

---

**h. Click Done to finalize your viewport-enabled tab.**

**7. Add components to your tab.** You build your tab just as you build a page.

**8. Add an event handler to any components to make them perform actions, such as loading page content.** For more information about event handlers, see *Events in UI Builder*.

**9. In Data driven tabs, select a data source to bind data to your viewport-enabled tab using data resources to dynamically expose your data from tables and records.** You then bind these data properties to components in your tab. For more information about using data resources, see *Data resources in UI Builder*. 
Data driven tabs

Choose where the viewport-enabled tab labels appear on the page. Also decide whether to hide tab labels so you only see the icons.

Set tab labels full width, or hide tab labels.
- Span tab labels full width of tabs container
- Hide all tab labels

Add a viewport to a contextual sidebar component

Adding a viewport to your page lets you create separate content that is viewed when you click a tab on your page. You create tabs within a component. Then, within those tabs, you can create custom pages or even third-party custom user interfaces.

Before you begin
Role required: ui_builder_admin

About this task
Create a viewport by adding a tab to a contextual sidebar component on your page. Then create content for the tab.

Procedure
1. Navigate to Now Experience Framework > UI Builder.
2. Open an experience to work in. Or, create a new experience by selecting Create experience in Platform. See Create an experience for more information.
3. Create or open a page.
4. Add a contextual sidebar component to your page.
5. Select your component and click **Edit content** to add a tab.

6. Design your content for the tab. Notice you are designing it in the edit content mode of UI Builder and not on the page itself. You can build the tab just like you would build a page. You can add components, change layouts, and so on. This example shows adding a tab to a contextual sidebar component.

7. Optional: Click the **Config** panel to edit the tab you created. When you add viewport tabs to a component in UI Builder, the Config panel changes to show the Tabs configuration. When you click a tab in the Config panel, the tab information changes in the corresponding component on the page.
Viewport component

Add a viewport component to your page to create separate content even if you do not own the content of the page itself. Create sub-pages, specify audiences, or customize content with different data, routes, and screens.

Viewport components use sub-pages within the component. A sub-page is similar to a page variant, but is specific to the viewport component. Treat a sub-page like any other page. Add components, use different layouts, and apply custom data and events to the sub-page to make it specific to your needs.

Viewport components can be added anywhere on a page.

Next step

Work with viewport components

Work with viewport components

Add a viewport component to your page and create a sub-page to create separate content on the page.

Before you begin

Role required: admin

Procedure

1. Navigate to Now Experience Framework > UI Builder.

2. Open an experience to work in. Or, create a new experience by selecting Create experience in Platform. See Create an experience for more information.

3. Open or create a page. If you open an existing page, ensure you are in the same scope as the original page. If not, change the scope before you start editing the page. Application scoping protects applications by identifying and restricting access to application files and data. Administrators set the scope to specify what parts of an application are accessible to other applications. Application scope protects data and application files. See Security and roles in UI Builder for more information on application scope.

4. Add a viewport component. From your page, select + and choose the Viewport component from the list, or drag and drop it to your page. You can search for the component or scroll through the list.
5. Define the audience for the viewport. Click the edit icon to the right of the viewport component in the Variants panel, then click **Edit audiences**.

   a. Select an audience, for example, **Admin**.

   b. Add an order if you want the audience to have a higher priority. The lower the number, the higher the priority.
c. Click **Done** to add the audience.

**Audience info**

**Add audiences**

Select one or more audiences for this page. If an audience you need is not listed, you can choose the Open audiences in platform link to create one.

No audiences, yet.

6. Select the viewport component, then click **Edit content**.
7. Click Create a sub-page to create a sub-page for the viewport component.
a. Name of sub-page: Enter a name for your sub-page. This example uses **Sub page for viewport component**.
b. Path: The path defaults to the name you entered, with hyphens added between words.
c. Optional: Choose a page template if you want to pre-define the sub-page.
d. Icon: Choose an icon to represent the sub-page, or go without an icon.
e. Order: Choose an order for the sub-page. The lower the number, the higher it is prioritized.
f. Application scope. The sub-page is created in the default application scope.
g. Click **Create** to create your sub-page.

8. Build your sub-page. Add components, data resources, and events as needed. Save your sub-page. In the following example, a list component is added to the sub-page.
9. Click **Back to viewport-component** to get out of the sub-page and return to the viewport component. Notice the sub-page is grayed-out to show it is a sub-page.
10. To make the viewport component active, you must add an event handler that contains the route and component ID.

a. Locate the viewport ID and route. You can see the ID and route in the Config panel as shown in the following figure.

b. Select the viewport component in the Content tree, then click **Edit content**.

c. Click **Events**, then select **Add a new event handler**.
d. From **Page-level event handlers**, click **UXF Macroponent Viewport Load Requested**.

**Add event handler**

**Event handler preview:** On, Row Clicked → Select event handler below.

- Search

- **Inherited event handlers**
  - Add alert notifications
  - Remove alert notifications
  - Clear alert notifications
  - Set loading state
  - Modal closed
  - Add parameters to URL
  - Open or close modal dialog
  - Link to destination
  - USER_PREF_UPDATED
  - Modal opened
  - Screen Close Confirmed
  - Form Header Updated
  - Screen Status Changed
  - Session Logged out

- **Page-level event handlers**
  - Add alert notifications
  - Remove alert notifications
  - Clear alert notifications
  - Set loading state
  - Update client state parameter
  - UXF Macroponent Viewport Load Requested

**e.** In **viewportElementID**, replace null with the viewport ID that you located in a previous step. In this example, it is, "viewport_tsj".

**f.** In **route**, replace null with the viewport component route that you located earlier in a previous step. In this example, it is, "Sub page for viewport component".
g. Click Add.

11. The sub-page that you create in the viewport component shows in the Config pane of the page. You can edit sub-pages at any time. The following example shows the Sub page for viewport component example created in this task.
12. Select **Open** to preview your page.

**Results**

1. You added a viewport component to a page.
2. You defined the audience for your viewport component.
3. You then created a sub-page to the viewport component, and added a list component.
4. You added an event handler to make the viewport component active.
5. You saved your work and opened it to preview what it looks like.

**Modals in UI Builder**

Use modals in Now® Experience UI Builder with components to provide alerts or calls to action for a user. UI Builder comes with modals to save time and effort.

A modal window disables the main page in UI Builder. A modal keeps the page visible with the modal window displayed in front of it. Users must interact with the modal before they can return to the main UI Builder page.

UI Builder has preconfigured modals available. You can add a modal to your component. Then, configure the content of the modal, and how it displays on the screen. Add an event handler to the modal to perform an action when a user selects it. The action can alert a user about something, or ask a user to confirm an action. A modal is a way to ensure that a user knows what is happening. For example, a modal may ask a user to confirm a selection before continuing whatever action they are performing on the main page.
**Modal types**

Different types of modals are available in UI Builder, as shown in the following table.

<table>
<thead>
<tr>
<th>Modal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert</td>
<td>An Alert modal provides information relating to the component action. For example, when a user presses a delete button, you could have an alert pop-up that lets the user know they cannot undo a delete action.</td>
</tr>
<tr>
<td>Confirm</td>
<td>A Confirm modal asks a user to confirm the component action. For example, when a user presses a delete button, the user would have to confirm the deletion of data. You can choose the confirm options from the primary and secondary button label fields, such as Yes/Cancel.</td>
</tr>
<tr>
<td>Confirm and destroy</td>
<td>A Confirm and destroy modal is more directive, usually relating to deleting or erasing content. It lets the user know the seriousness of an action, and asks them whether they want to proceed with the action.</td>
</tr>
<tr>
<td>Custom</td>
<td>Custom modals address scenarios that are not handled using the standard modals. Custom modals can be thought of as a container component on a modal. You can add a custom layout, components, events, and data resources just like you do on a page. The custom modal uses layouts to let you fully design what information you want in the modal. Layouts also decide where the information sits within the modal screen. You can use Cascading Style Sheets (CSS) styling to change the visual look of the modal.</td>
</tr>
<tr>
<td>Modal type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>iframe</td>
<td>Use iframe to bring content into your modal from existing iframe content from a URL and data.</td>
</tr>
<tr>
<td>Modal viewport</td>
<td>Dynamically pass content into your viewport modal through an event binding using a client script.</td>
</tr>
</tbody>
</table>

**Event handlers and modals**

Exposé events to modals to handle call-to-action events. For example, a primary action, secondary action, and so on. You configure the data by adding an event handler and invoking a data resource. It is as simple as adding a new event handler for the component that has a modal. Or you can add an event handler to the modal itself. You select the event you want associated with the component or modal and add it. See Add modal to component for detailed instructions.

**Add modal to component**

Learn how to add a modal in Now® Experience UI Builder. A modal is a window that appears when you click a component. For example, add a button component that deletes a record. Then, add a modal to ask the user to confirm they want to delete the record.

**Before you begin**

Role required: ui_builder_admin

**About this task**

Add a modal to a component and add an event handler. This task uses a button component with a confirm modal as an example.

**Procedure**

1. Navigate to Now experience framework > UI Builder.
2. Open an experience to work in. Or, create a new experience by selecting Create experience in Platform. See Create an experience for more information.
3. Open or create a page.
4. Add a component to your page, such as a button component. See Add components to a page for more information.
5. Add a modal to the component. A modal is a screen that appears when you click a component such as a button.
a. Select the component to highlight it, either in the content tree, or on the page itself. When you highlight a component, you can configure it.

b. Select **+Add > Modal** in the content section.

c. Choose a modal type such as **Confirm**. You can choose from the six modal types.

<table>
<thead>
<tr>
<th>Modal type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert</td>
<td>An alert modal provides information relating to the component action. For example, when a user presses a delete button, you could have an alert pop-up that lets the user know they cannot undo a delete action.</td>
</tr>
<tr>
<td>Confirm</td>
<td>A Confirm modal asks a user to confirm the component action. For example, when a user presses a delete button, the user would have to confirm the deletion of data. You can choose the confirm options from the primary and secondary button label fields, such as Yes/Cancel.</td>
</tr>
<tr>
<td>Modal type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Confirm and destroy</td>
<td>A Confirm and destroy modal is more directive, usually relating to deleting or erasing content. It lets the user know the seriousness of an action, and asks them whether they want to proceed with the action.</td>
</tr>
<tr>
<td>Custom</td>
<td>The custom modal uses layouts to let you fully design what information you want in the modal. Layouts also decide where the information sits within the modal screen. You can use Cascading Style Sheets (CSS) styling to change the visual look of the modal, such as background color.</td>
</tr>
<tr>
<td>iframe</td>
<td>Use iframe to bring content into your modal from existing iframe content from a URL and data.</td>
</tr>
<tr>
<td>Modal viewport</td>
<td>Dynamically pass content into your viewport modal through an event binding using a client script. See Bind an event to a component for more information on binding an event to a component.</td>
</tr>
</tbody>
</table>

d. Configure the modals as shown in the table. Configure each modal differently, depending on what the modal requires. Change what information goes into the modal, the size of the modal, and how it looks. You can add an event handler to the modal that performs the action for the modal, such as opening or closing the modal.

<table>
<thead>
<tr>
<th>Modal</th>
<th>Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alert</td>
<td>• Add a header, which is the title of the modal.</td>
</tr>
<tr>
<td></td>
<td>• Write the content that you want displayed in the modal. The content tells the user what the alert is.</td>
</tr>
</tbody>
</table>
Modal Configuration

- Add text for the button label. It can be anything you want, such as **OK**, **Yes**, and so on.

- Choose the size of the modal on the screen. Select **Small**, **Medium**, **Large**, or **Fullscreen**.

- Enable or disable **Prevent Default Button Action**, depending on whether you want the modal to close based on the default action.

- Enable or disable **Defer modal content loading**. If you disable it, the modal loads with the page. If you enable it, the modal doesn’t load when the page loads.

- Select **Events > Add a new event handler** to add an event handler to the modal.

- Select an event handler to apply to the modal, then select **Add** to add it to the page. Choose from inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the
## Modal Configuration

- Add a header, which is the title of the modal.
- Write the content that you want displayed in the modal. The content tells the user what the alert is.
- Add text for the primary button. The primary button is the main action button for users, such as **Yes**, **Add**, and so on.
- Add text for the secondary button. The secondary button is usually the no choice for users, such as **Cancel**, **No**, and so on.
- Choose the size of the modal on the screen. Select **Small**, **Medium**, **Large**, or **Fullscreen**.
- Enable or disable **Prevent Default Primary Button Action**, depending on whether you want the modal to close based on the default action.
- Enable or disable **Prevent Default Secondary Button Action**, depending on whether you want...
## Modal Configuration

The modal to close based on the default action.

- Enable or disable **Defer modal content loading**. If you disable it, the modal loads with the page. If you enable it, the modal doesn't load when the page loads.

- Select **Events > Add a new event handler** to add an event handler to the modal.

- Select an event handler to apply to the modal. Choose from inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the user session for GraphQL, or a user session for Transform.

## Confirm or destroy

- Add a header, which is the title of the modal.

- Write the content that you want displayed in the modal. The content tells the user what the alert is.
### Modal Configuration

- **Add text for the primary button.** Primary is the main action button for users, such as **Delete** or **Erase**.
- **Add text for the secondary button.** The secondary button is usually the no choice for users, such as **Cancel, No**, and so on.
- **Choose the size of the modal on the screen.** Select **Small, Medium, Large**, or **Fullscreen**.
- **Enable or disable Prevent Default Primary Button Action,** depending on whether you want the modal to close based on the default action.
- **Enable or disable Prevent Default Secondary Button Action,** depending on whether you want the modal to close based on the default action.
- **Enable or disable Defer modal content loading.** If you disable it, the modal loads with the page. If you enable it, the modal doesn't load when the page loads.
- **Select Events > Add a new event handler** to add an event handler to the modal.
- **Select an event handler to apply to the modal.** Choose from inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the

user session for GraphQL, or a user session for Transform.

- Choose a layout for your modal. You can select no columns, multiple columns, rows, and so on. The layout lets you add content in your modal however you want.

- Use CSS styling to change how your modal looks. You can apply any standard CSS styling to your modal, such as background color.

- Select **Events > Add a new event handler** to add an event handler to the modal.

- Select an event handler to apply to the modal. Choose from inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the
## Modal Configuration

- Add a header, which is the title of the modal.
- Add a source URL that points to your existing iframe content.
- Set the parameters and initial data that you want to iframe.
- Choose the size of the modal on the screen. Select **Small**, **Medium**, **Large**, or **Fullscreen**.
- Turn on **disable sandbox** to lift the following restrictions: allow-forms, allow-modals, allow-popups, allow-presentation, allow-same-origin, allow-scripts, and allow-downloads options. Turn off the **disable sandbox** to only lift the allow-scripts option.
- Enable or disable **Defer modal content loading**. If you disable it, the modal loads with the page. If you enable it, the modal doesn’t load when the page loads.
- Select **Events > Add a new event handler** to add an event handler to the modal.
Modal configuration

• Select an event handler to apply to the modal. Choose from inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the user session for GraphQL, or a user session for Transform.

Modal viewport

• Choose the size of the modal on the screen. Select Small, Medium, Large, or Fullscreen.

• Route any viewport contents to your modal by adding a script in the Viewport Contents field.

• Enable or disable Disable Dismiss. If enabled, the modal omits the dismiss icon. Pressing Escape doesn’t close the modal. This property only works for Bare Modals (select Bare as true in Event Mapping).

• Select Events > Add a new event handler to add an event handler to the modal.

• Select an event handler to apply to the modal. Choose from
Modal Configuration

inherited or page-level event handlers. Event handlers perform an action such as open or close a modal. Depending on the modal type, you can refresh data for the App Shell data source, the user session for GraphQL, or a user session for Transform.

6. When you finish configuring the modal, close it. Notice in the content tree that the modals you create sit above the body of your page structure.

Layouts in UI Builder

Layouts control what slots are available in a container on a page, and how these slots are organized. Learn how layouts are used in User Interface (UI) Builder.
Think about the layout of your page before you begin building it. Think about what you want to achieve and how complex the page layout must be. These questions determine what type of layout you will use.

Cascading Style Sheets (CSS) rules apply to layouts. Layouts can also specify empty spaces on a page that components cannot be inserted into. Changing the layout on an existing page will discard the component placements that were made to the page.

Layouts in UI Builder use standards-based CSS web layout technologies such as flexbox, CSS grid, and absolute positioning. So whatever you can do in CSS you can do here. Visit Mozilla to learn more about CSS.

The legacy UI Builder 12-column/row-column layout is also available, although you should use flexbox and CSS grid. For more information about using Flexbox and CSS Grid, see Change the layout of a page.

**Slots and containers in layouts**

Containers are a type of component that contains other components. Containers have layout properties applied to them.

Slots define where containers can be placed in a layout. Slots can hold a component, which could be a container. Slots support layout nesting, which is when one layout is inside another. In this example, your container has slot A and slot B. Slot B has another container inside with four more slots defined.
Types of layout systems

Flexbox is excellent for laying out items in a single dimension, such as a row of items flexibly spaced, or a column of unequally sized items vertically centered and spaced. Flexbox is used with a single slot that has multiple components within it. Components can be spaced in a row or column without needing a separate container with additional slots to maintain and style.

CSS Grid works well for larger layouts with a mix of columns and grids. CSS Grid lets you to position elements across these two dimensions. CSS Grid can also represent a literal grid with X number of columns, and Y number of rows.

A larger layout, such as one for the overall page, can easily incorporate things like a header, main content with two side bars, and a footer that is always at the bottom of your content. Instead of using multiple containers with different layout types applied, you can build a custom page layout that incorporates an overall grid page layout, with room for flex-based slots that will space out your content automatically as needed. You can add additional slots when necessary for additional content instead of containers.

The following table describes the Flexbox and CSS Grid layout systems.

<table>
<thead>
<tr>
<th>Layout system</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flexbox</td>
<td>Flexbox is a one-dimensional layout system in CSS. Flexbox is inherently flexible, which is useful for when you do not know the size of your content. You can change the direction of your content in the layout in the following ways:</td>
</tr>
<tr>
<td></td>
<td>• Row: Rows are organized left-to-right or right-to-left, depending on the direction of your browser's default language. Left/right is the case for an English browser.</td>
</tr>
<tr>
<td></td>
<td>• Row-reverse: Rows are organized in the reverse direction of your browser's default language, such as right-to-left or left-to-right.</td>
</tr>
<tr>
<td></td>
<td>• Column: Up/down or down/up</td>
</tr>
<tr>
<td></td>
<td>• Column-reverse: Down/up</td>
</tr>
<tr>
<td>Layout system</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>Flexbox row and column directions</strong></td>
<td></td>
</tr>
<tr>
<td><img src="image" alt="Diagram" /></td>
<td></td>
</tr>
</tbody>
</table>

- **Justify content**: Defines the alignment along the main axis. Choices are as follows:
  - Flex-start: Items are at the start of the flex direction, similar to left-justified content. This is the default setting.
  - Flex-end: Items are at the end of the flex direction, similar to right-justified content.
  - Space-between: Items are distributed evenly.
  - Space-around: Items are distributed evenly with equal space around them.
  - Space-evenly: The spacing between items is equal.

- **Align items**: Defines how you want your flex content displayed along the cross axis. Choices are as follows:
  - Stretch: Stretch your content to fill the container. This is the default setting.
  - Flex-start: Place your content at the start of the cross axis.
  - Flex-end: Place your content at the end of the cross axis.
## Layout systems (continued)

<table>
<thead>
<tr>
<th>Layout system</th>
<th>Description</th>
</tr>
</thead>
</table>
|               | ◦ Center: Center your content in the cross axis.  
|               | ◦ Baseline: Align your content the same as your baseline alignment.  
|               | • Height: Set the height automatically or manually.  
|               | • Width: Set the height of your flexbox items automatically or manually.  
|               | • Margin: Set your minimal distance between flexbox items.  
|               | • Padding: Set the padding for each side of your flexbox items.  
|               | See [Create a Flexbox layout to build a page](#) for more information. |

**CSS Grid**  
CSS Grid is the most powerful layout system in CSS. CSS Grid is built on top of a two-dimensional grid. CSS Grid gives you control over how you create your pages. For example, you can have a grid with three columns and nine cells. Five slots are built on top of the grid. The header slot spans three columns and three cells. A footer slot also spans three columns and cells. And three slots exist in the middle columns, with the middle slot larger than the left and right slots.  
To find out more about CSS layouts within your UI Builder instance, you can find them in the [sys_uib_template] table.
## Change the layout of a page

Add and modify your layout design to change the way your page looks. Choose how components are displayed on a page through Cascading Style Sheets (CSS) web layout technologies such as Flexbox and CSS Grid.

### Before you begin
Role required: ui_builder_admin

### About this task
Layouts control what slots are available on a page, and where they are. CSS rules apply to them. You can change the layout as follows.

### Procedure
1. Navigate to **Now Experience Framework > UI Builder**.
2. Open an experience to work in or create a new experience by selecting **Create experience in Platform**.

---

### Layout systems (continued)

<table>
<thead>
<tr>
<th>Layout system</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSS Grid layout</td>
<td>[Image of CSS Grid layout] &lt;br&gt;See <a href="#">Create a CSS Grid layout to build a page</a> for more information.</td>
</tr>
<tr>
<td>Standard row/column</td>
<td>Standard row/column layout uses the legacy UI Builder 12-column grid and row system. Flexbox and CSS Grid provide you with more control over the page layout. You should use them instead of the legacy standard row/column layout.</td>
</tr>
</tbody>
</table>
See Create an experience for more information on creating experiences.

3. Create or open a page.
4. Select the Layout tab.
5. Depending on the type of page, do one of the following to select a container to update.

<table>
<thead>
<tr>
<th>Type of page</th>
<th>Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Existing page</strong></td>
<td>Select the container on your page for which you want to change the layout.</td>
</tr>
<tr>
<td></td>
<td>Note: Alternately, you can select the container in the content tree to the left of the main page area. When the page structure is in the structured tree, you can more easily find the container you want to change. If you have many components and containers in the content tree, use the search bar to find a specific container.</td>
</tr>
<tr>
<td><strong>New page</strong></td>
<td>In the content tree to the left of the main page area, select the <strong>Body</strong> of your page. <strong>Body</strong> is the root element of the page.</td>
</tr>
</tbody>
</table>

If you are starting a new page, you can select the layout at the page level, and later at the container level. If you are not the owner of an existing page, be aware of the impact of changing the layout at the page level.

6. To change the layout of your container, do the following:
a. In the Page configuration pane, select the **Layout** tab to select the layout that you want to use.

You can change the current layout of an existing page into a new one. For example, in a three-column layout, you can click the four-column layout to change the layout.

You can also set the layout for a container. The following image shows the layout options for the UI Builder.

![Layout Options](image)

b. If you are creating a page, add components to the new areas in your layout.

c. Click **Save**.

d. To see a preview of the page, click **Open**.

**Example**

For changing an existing page, the following video shows how you can change the container layout from three to four columns, and then add a new component to the fourth column.
For setting the layout of a new page, the following video shows you how to set the layout that you want for the page. For example, you can set your page to have two slots or columns. Then, you can add containers to each slot and change the layout for each container. You can also set the layout at the container level after you add containers to your page.
7. Add components to slots.
   You build your page with containers components. See Work with components for more information.
   You can add components by using any of the following ways.

<table>
<thead>
<tr>
<th>Option</th>
<th>Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>a. Select the components icon (מגש) in the left column of UI Builder.</td>
</tr>
<tr>
<td></td>
<td>b. Drag a component from the component list onto your page.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option</th>
<th>Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Directly from your page</td>
<td>From your page, select the +Add icon (+Add) and choose a component from the list. You can search for a component or scroll through the list.</td>
</tr>
<tr>
<td>Floating menu above the page</td>
<td>Click the menu icon (Ⅲ) above your component, and choose <strong>Add component</strong>.</td>
</tr>
<tr>
<td>Option</td>
<td>Instruction</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>Select + Add component, then select Component.</td>
</tr>
</tbody>
</table>

8. Modify the layout styling options in any of the following ways.
### Change the layout styling

<table>
<thead>
<tr>
<th>Option</th>
<th>Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>a.</td>
<td>Click a container for which you want to change the layout. You can click the container in the content tree, or you can click the container on the page.</td>
</tr>
<tr>
<td>b.</td>
<td>From the floating menu above the page, click <strong>Layout</strong>.</td>
</tr>
<tr>
<td>c.</td>
<td>Choose to display your content as either Flex or Grid. For more information about flex or grid options, see Change the layout of a page.</td>
</tr>
</tbody>
</table>

### Choose Flex

<table>
<thead>
<tr>
<th>Display</th>
<th>Flex</th>
<th>Flex</th>
<th>Grid</th>
</tr>
</thead>
</table>

**a.** From the Display list, select **Flex**.

**b.** Select the following options based on how you want to display your container content on the page. The options can also be entered in the CSS styles box.

- **Flex direction:** Choose from **Row**, **Row-reverse**, **Column**, or **Column-reverse**.
- **Justify content:** Choose from any of the following:
  - **Flex-start:** Items are at the start of the flex direction, similar to left-justified content. This is the default setting.
  - **Flex-end:** Items are at the end of the flex direction, similar to right-justified content.
  - **Space-between:** Items are distributed evenly.
<table>
<thead>
<tr>
<th>Option</th>
<th>Instruction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Space-around</td>
<td>Items are distributed evenly with equal space around them.</td>
</tr>
<tr>
<td>Space-evenly</td>
<td>The spacing between items is equal.</td>
</tr>
<tr>
<td>Align items</td>
<td>Defines how you want your flex content displayed along the cross axis.</td>
</tr>
<tr>
<td></td>
<td>Choices are as follows:</td>
</tr>
<tr>
<td></td>
<td>◦ Stretch: Stretch your content to fill the container. This is the default</td>
</tr>
<tr>
<td></td>
<td>setting.</td>
</tr>
<tr>
<td></td>
<td>◦ Flex-start: Place your content at the start of the cross axis.</td>
</tr>
<tr>
<td></td>
<td>◦ Flex-end: Place your content at the end of the cross axis.</td>
</tr>
<tr>
<td></td>
<td>◦ Center: Center your content in the cross axis.</td>
</tr>
<tr>
<td></td>
<td>◦ Baseline: Align your content the same as your baseline alignment.</td>
</tr>
<tr>
<td>Height</td>
<td>Set the height automatically, or manually.</td>
</tr>
<tr>
<td>Width</td>
<td>Set the height of your flexbox items automatically or manually.</td>
</tr>
</tbody>
</table>

<td>Set the padding for each side of your grid items.</td>
</tr>
</tbody>
</table>

Create a Flexbox layout to build a page

Create a Flexbox layout in Now Experience UI Builder to build powerful pages so that you can customize with cascading style sheets (CSS) and can improve your performance.

Before you begin
Role required: admin

About this task
You can easily build pages with the layouts that are included with UI Builder. If you plan to build complex pages, you can customize the layout of your page with CSS. Customizing the layout of your page lets you take full advantage of Flexbox so that you can achieve your overall page design. For more information, see Types of layout systems.

In the following procedure, you learn how to use Flexbox to modify your CSS to customize the layout of your page.

Procedure
1. Navigate to Now Experience Framework > UI Builder.
2. Open an experience to work in or create a new experience by selecting Create experience in Platform.
   For more information, see Create an experience for UI Builder.
3. Create a page in UI Builder or open a page.
4. Click the Layout tab and choose the two-column layout.
5. Click **Edit layout code**.

6. Expand the code editor so that you can easily view the CSS code.
7. Add another slot to the layout by copying the CSS code for an existing slot. Copying the code is easier than typing it into the layout.

Copy the CSS code for a slot

8. Below the code that you copied, place a comma and then paste the following CSS code:
   a. Change the "slotName" property to "Column 3",
   b. Change the "flex" property to "2",
   c. Add "margin-left": "1rem".
Changing the "flex" property increases the size of the column. By using "margin-left", you add space between the previous columns.
9. Collapse the expanded view, and then click **Apply**.

Apply a layout change

Update your page's layout

Changes made here will overwrite the existing configuration.

```json
{  "slotName": "Column 3",  "rules": {    "flex": "2",    "margin-left": "1rem"  },  "styles": {    "display": "flex",    "flex-direction": "column"  },  "root": null}
```

Results

The new Flexbox layout that you created shows the new slot that you added to the original two-column layout.
Click **Reset to original** to reset these layout changes back to the original at any time.

**Related information**

- Create a CSS Grid layout to build a page

**Create a CSS Grid layout to build a page**

Create a CSS Grid layout in Now® Experience UI Builder to build powerful pages so that you can customize with cascading style sheets (CSS) and can improve your performance.
Before you begin
Role required: admin

About this task
You can easily build pages with the layouts that are included with UI Builder. If you plan to build complex pages, you can customize the layout of your page by using CSS. Customizing the layout of your page lets you take full advantage of CSS Grid so that you can achieve your overall page design. For more information, see Types of layout systems.

In the following procedure, you learn how to use CSS Grid to modify your CSS to customize the layout of your page.

Procedure
1. Navigate to **Now Experience Framework > UI Builder**.
2. Open an experience to work in or create a new experience by selecting **Create experience in Platform**.
   See [Create an experience for UI Builder](#) for more information.
3. Create a page in UI Builder or open a page.
4. Click the **Layout** tab and choose the two-row by two-column layout.
5. Click **Edit layout code**.
6. Expand the code editor so that you can easily view the CSS code.

7. Add another slot to the layout by copying the CSS code for an existing slot. Copying the CSS code is easier than typing it into the layout.
Copy the CSS code for a slot

```
Copy the CSS code for a slot

8. Paste the CSS code below the code that you copied and change the
   slotName and grid-area to a unique value.
```
9. Modify the layout rules to include the new column and template area, as follows:

a. Delete the "Grid-template-columns": "1fr 1fr", line.

b. Add a second cell1 after cell1, and then add cell5 after cell4.

You can set many different configurations. In this example, there are the two resulting grids from two different grid template areas. The "grid-template-areas" property being modified is setting the CSS property of the same name. For more information, see MDN grid-templates-areas.
10. Collapse the expanded view, and then click **Apply**.

**Apply a layout change**
**Update your page's layout**

---

**Results**
The new CSS Grid layout shows that the new slot was added to the original two-row, two-column layout.
Click **Reset to original** to reset the layout changes back to the original at any time.

Create a Flexbox layout to build a page

**Themes in UI Builder**

Themes enable you to change the visual style of your app's experiences so that they express the look and feel of your brand.

**Note:** You can only apply themes to CSM Configurable Workspace and the Workspace and Portal experiences for App Engine Studio. To create a theme for a mobile app, see Mobile themes.
Getting started with themes
Before creating a theme to apply to your experience, create a theming plan for all of the experiences that your users interact with. Your theming plan can consider the following questions:

• What kinds of experiences do my users interact with?
• What similarities and differences should the visual styles of these experiences have?

For example, if you just want to create one theme that represents a singular branding look and feel throughout all of your experiences, then you might want to only create a main theme. However, if you want to represent multiple branding variations that are based on an overall brand style, then you can create a main theme and then extend that theme to create theme variations.

Creating your main theme
Your main theme represents the overall look and feel of your organization’s brand. When creating a main theme, consider the following:

• Which brand colors do you want to display to users for the following types of elements?
  1. Primary, or the most important, actions.
  2. Secondary, or complementary, actions.

After choosing your brand colors, you can then assign color values, as RGB triplets, to the following Now® Experience CSS custom properties for theming.

Now® Experience CSS custom properties for theming

<table>
<thead>
<tr>
<th>CSS custom property</th>
<th>RGB color value to assign</th>
</tr>
</thead>
<tbody>
<tr>
<td>--now-color_brand--primary</td>
<td>Your primary brand color.</td>
</tr>
<tr>
<td></td>
<td>Note: A saturated, darker color works best, because this color frequently appears on a light background. Dark backgrounds are not currently supported.</td>
</tr>
<tr>
<td>--now-color--primary-1</td>
<td>Same as previous. Your primary brand color.</td>
</tr>
</tbody>
</table>

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Now® Experience CSS custom properties for theming (continued)

<table>
<thead>
<tr>
<th>CSS custom property</th>
<th>RGB color value to assign</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Note: A saturated, darker color works best, because this color frequently appears on a light background. Dark backgrounds are not currently supported.</td>
</tr>
<tr>
<td>--now-color--primary-0</td>
<td>Slightly lighter variation of your primary brand color.</td>
</tr>
<tr>
<td>--now-color--primary-2</td>
<td>Slightly darker variation of your primary brand color.</td>
</tr>
<tr>
<td>--now-color--primary-3</td>
<td>Darkest variation of your primary brand color.</td>
</tr>
<tr>
<td>--now-color_brand--secondary</td>
<td>Your secondary brand color.</td>
</tr>
<tr>
<td>--now-color--secondary-1</td>
<td>Same as previous. Your secondary brand color.</td>
</tr>
<tr>
<td>--now-color--secondary-0</td>
<td>Slightly lighter variation of your secondary brand color.</td>
</tr>
<tr>
<td>--now-color--secondary-2</td>
<td>Slightly darker variation of your secondary brand color.</td>
</tr>
<tr>
<td>--now-color--secondary-3</td>
<td>Darkest variation of your secondary brand color.</td>
</tr>
</tbody>
</table>

You can then use these CSS custom properties in a Theme [sys_ux_theme] record to Create a custom theme.

Note: Your instance doesn’t apply your main theme to all of your experiences automatically. To learn more about how to apply your main theme to an experience, see Apply a theme to your experience.

The following images demonstrate where Now® Experience CSS custom properties appear in a Workspace and Portal. Refer to these images when determining which CSS custom properties to use in your theme.
Where CSS custom properties appear in a Workspace experience

Workspace

Note: To change the banner image, you must do the following:

1. Upload a new image at System UI > Images.
2. From the Image [db_image] record, copy the value of the Name field.
3. In UI Builder, select the Hero Banner's Row container.
4. In CSS styles, set the value of the background-image property to the URL for the copied image's name. For example, if your image's name is my_image.png, set the value of background-image to url(my_image.png).

Creating variations on your main theme
You can create variations on your main theme depending on the type of experience that you're building for your users. When creating a variation on a main theme to apply to an experience, consider the following questions:

- What roles do your users have in this experience?
- What tasks are your users focusing on the most in this experience?
- How might your users be feeling when working in this experience?

Asking your team these questions can help you better understand your approach for creating a variation on your main theme. For example, assume you’re creating a theme variation for fulfillers who have strict SLAs for completing actions in a Workspace. Then, you should consider calling more attention to primary and secondary actions in the Workspace by transforming all button text to uppercase.

The following is an example of how to style a main theme and two variations on a main theme:

---

**Main Workspace theme**

- Primary brand color: blue
- Secondary brand color: purple

**Workspace Theme A**
- Inherits: Primary brand color: blue
- Overrides: Secondary brand color: green
- Adds: More rounding to button borders

**Workspace Theme B**
- Inherits: Primary brand color: blue
- Secondary brand color: purple
- Adds: Thicker border to menus
- All uppercase text to button labels

---

**Note:** Your instance doesn't apply your main theme and theme variations to experiences automatically. To step through an example of creating a main theme and a variation on a main theme, see Extend a theme.
**Theme variables in CSS editor**

When you define theme variables in the [sys_ux_theme] table, you can use them directly in the UI Builder Styles CSS editor to add styling to your pages.

UI Builder will intelligently predict or suggest theme variables that you defined in your theme, as well as CSS properties and values to you as you type your CSS configuration.

Use the open icon () icon to expand the CSS styles editor in a modal. The expanded modal provides a search option and a larger space to work in so you can fully view the variables. The expanded editor also shows two tabs. The Editor tab shows a full view of the CSS code. The Variables tab shows the variables defined by the user’s theme.

### Theme Preview template

Create a new page and apply the Theme Preview page template to see how an applied theme looks on a page.
The theme preview page shows how common components will look with the theme applied to them. For example, a theme preview page will look similar to the following, depending on what theme you have defined.

Create a custom theme

Create a custom theme so that you can override default component styles. You can define your own style properties in a theme record.
Before you begin
Role required: ui_builder_admin or admin

About this task
Themes enable you to change the visual style of your app’s experiences so that they express the look and feel of your brand. Before creating a own custom theme for only one experience, consider creating a theming plan for your app. For more information, see Themes in UI Builder.

Note: You can apply themes to CSM Configurable Workspace and only to experiences created in App Engine Studio.

Procedure
1. To apply a theme, do one of the following:
   - Follow the steps to Apply a theme to your experience:
     a. Navigate to Menu > Edit experience settings > Branding and theming.
     b. On the Brand and theming settings screen under Themes, select Create a theme.
   - Navigate to Now Experience Framework > Themes.
The Themes list view appears.
2. To create a new theme record in the Theme [sys_ux_theme] table, click New.
3. On the form, fill in the fields.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name that describes your theme. This name appears in the list of selectable themes in the UI Builder Experience Settings menu.</td>
</tr>
<tr>
<td>Description</td>
<td>Detailed description for your theme.</td>
</tr>
<tr>
<td>Extends</td>
<td>Another theme record that inherits from your styling configurations. To inherit default ServiceNow fonts and component spacing, select the lookup using list icon and then select the Default theme from the list. For more information on how to extend a theme from your main custom theme, see Extend a theme.</td>
</tr>
<tr>
<td>Application</td>
<td>Application that contains your experience.</td>
</tr>
<tr>
<td>Active</td>
<td>Leave selected.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>Domain</td>
<td>Domain that is associated with your create. For more information, see domain-separated themes.</td>
</tr>
<tr>
<td>Override</td>
<td>This field should be left empty.</td>
</tr>
</tbody>
</table>
| Theme   | Enter Now® Experience CSS custom properties and values for your theme, formatted as a JSON object.  
When configuring your theme in this field, consider the following questions:  
- Which brand colors do you want to display to users for the following types of elements?  
  a. Primary, or the most important, actions.  
  b. Secondary, or complementary, actions.  
After choosing your brand colors, you can then assign color values, as RGB triplets, to the following Now® Experience CSS custom properties for theming. |

**Now® Experience CSS custom properties for theming**

<table>
<thead>
<tr>
<th>CSS custom property</th>
<th>RGB color value to assign</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--now-color_brand--primary</code></td>
<td>Your primary brand color.</td>
</tr>
<tr>
<td><strong>Note:</strong> A saturated, darker color works best, because this color frequently appears on a light background. Dark backgrounds are not currently supported.</td>
<td></td>
</tr>
<tr>
<td><code>--now-color--primary-1</code></td>
<td>Same as previous. Your primary brand color.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td><strong>CSS custom property</strong></td>
<td><strong>RGB color value to assign</strong></td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> A saturated, darker color works best, because this color frequently appears on a light background. Dark backgrounds are not currently supported.</td>
</tr>
<tr>
<td>--now-color--primary-0</td>
<td>Slightly lighter variation of your primary brand color.</td>
</tr>
<tr>
<td>--now-color--primary-2</td>
<td>Slightly darker variation of your primary brand color.</td>
</tr>
<tr>
<td>--now-color--primary-3</td>
<td>Darkest variation of your primary brand color.</td>
</tr>
<tr>
<td>--now-color_brand--secondary</td>
<td>Your secondary brand color.</td>
</tr>
<tr>
<td>--now-color--secondary-1</td>
<td>Same as previous. Your secondary brand color.</td>
</tr>
<tr>
<td>--now-color--secondary-0</td>
<td>Slightly lighter variation of your secondary brand color.</td>
</tr>
<tr>
<td>--now-color--secondary-2</td>
<td>Slightly darker variation of your secondary brand color.</td>
</tr>
<tr>
<td>--now-color--secondary-3</td>
<td>Darkest variation of your secondary brand color.</td>
</tr>
</tbody>
</table>

The following images demonstrate where Now® Experience CSS custom properties appear in a Workspace and Portal. Refer to these images when determining which CSS custom properties to use in your theme.
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>

Where CSS custom properties appear in a Workspace experience

**Workspace**

![Workspace Image]

Where CSS custom properties appear in a Portal experience

**Portal**

![Portal Image]

**Note:** To change the banner image, you must do the following:

a. Upload a new image at **System UI > Images**.

b. From the Image [db_image] record, copy the value of the **Name** field.

c. In UI Builder, select the Hero Banner's Row container.

d. In CSS styles, set the value of the **background-image** property to the URL for the copied image's name.

For example, if your image's name is **my_image.png**, set the value of **background-image** to **url(my_image.png)**.

The following is an example theme configuration snippet.

```json
{
    "--now-color_brand--primary": "23,64,139",
    "--now-color--primary-1": "23,64,139",
    "--now-color--primary-0": "220,226,238",
    "--now-color--primary-2": "18,48,105",
    "--now-color--primary-3": "12,32,70",
    "--now-color_brand--secondary": "201,8,42",
    "--now-color--secondary-1": "201,8,42",
    "--now-color--secondary-0": "247,218,223",
    "--now-color--secondary-2": "151,6,32",
    "--now-color--secondary-3": "151,6,32"
}
```

**Note:** Hex color values are not supported in a Theme [sys_ux_theme] record. All color values must be RGB triplets.

4. To finish creating your theme, select **Submit**.

**What to do next**
Apply your theme to an experience so that your custom styles get applied to all of the visual elements in your app. For more information, see **Apply a theme to your experience**.

**Extend a theme**
Create a variation on your main theme by extending it to another theme.

**Before you begin**
Role required: ui_builder_admin or admin

**About this task**
Extending a Theme [sys_ux_theme] record to another Theme record enables you to create a variation on your main theme for a specific experience. After extending a theme, you can then override inherited styles from the main theme by setting more specific styles in the extended theme variation. For example, you can create your organization's main branding theme. You can then extend that theme to a Workspace theme with some customized styles specific to the Workspace.

The following procedure walks you through an example of how to create a main theme and then extend that theme and customize its style configurations for a
Workspace. For more information on how to create and extend themes using Now® Experience CSS custom properties, see Themes in UI Builder.

**Procedure**

1. Do one of the following:
   - Follow the steps to Apply a theme to your experience:
     a. Navigate to **Menu > Edit experience settings > Branding and theming.**
     b. On the Brand and theming settings screen under Themes, select **Create a theme.**
   - Navigate to **Now Experience Framework > Themes.** The Themes list view appears.

2. Click **New** to create a new Theme [sys_ux_theme] record.

3. On the form, fill in the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter the name of your theme extension, for example, <em>My Main Theme</em></td>
</tr>
<tr>
<td>Description</td>
<td>Describe the theme extension.</td>
</tr>
<tr>
<td>Extends</td>
<td>Select the lookup using list icon (🔍) and then select the <strong>Default</strong> record from the list.</td>
</tr>
</tbody>
</table>
   | Theme   | Enter the following:

```plaintext
{
    "--now-color_brand--primary": "23,64,139",
    "--now-color--primary-1": "23,64,139",
    "--now-color--primary-0": "220,226,238",
    "--now-color--primary-2": "18,48,105",
    "--now-color--primary-3": "12,32,70",
    "--now-color_brand--secondary": "201,8,42",
    "--now-color--secondary-1": "201,8,42",
    "--now-color--secondary-0": "247,218,223",
    "--now-color--secondary-2": "151,6,32",
    "--now-color--secondary-3": "151,6,32"
}
```
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>Hex color values are not supported in a Theme [sys_ux_theme] record. All color values must be RGB triplets.</td>
</tr>
<tr>
<td>Active</td>
<td>Select to make this theme extension active.</td>
</tr>
<tr>
<td>Override</td>
<td>Leave this field empty.</td>
</tr>
</tbody>
</table>

4. Leave all other fields as they are, and then select **Submit** to finish creating the main theme. The Themes list view appears again.

5. In the context header, select **New** to create another Theme record.

6. In the form, fill in the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Enter <strong>My Workspace Theme</strong></td>
</tr>
<tr>
<td>Description</td>
<td>Describe the theme extension.</td>
</tr>
<tr>
<td>Extends</td>
<td>Select the lookup using list icon (🔍) and then select the <strong>My Main Theme</strong> record from the list.</td>
</tr>
<tr>
<td>Theme</td>
<td>Enter the following code:</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;--now-actionable--text-transform&quot;: &quot;uppercase&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;--now-actionable--border-radius&quot;: &quot;30px&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;--now-actionable--border-width&quot;: &quot;5px&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;--now-window--border-radius&quot;: &quot;30px&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;--now-window--border-width&quot;: &quot;5px&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>

**Note:** Hex color values are not supported in a Theme [sys_ux_theme] record. All color values must be RGB triplets.
7. Leave all other fields as they are, and then select **Submit** to finish creating the Workspace theme.
   Your main theme now extends to your Workspace theme. Styles set in your main theme are inherited by the Workspace theme unless a more specific style in the Workspace theme overrides the inherited style.

**What to do next**
Now that you’ve created a main theme and an extended theme variation, try applying a theme to your experience.

**Apply a theme to your experience**
Apply a theme to change the visual style of your experience and provide a consistent look and feel across all pages.

**Before you begin**
Role required: ui_builder_admin or admin

**About this task**
Themes enable you to override default component styles, such as fonts and colors. You can create a consistent look and feel across your entire experience.

With Theme [sys_ux_theme] records, you can set style properties that are passed down to all of the visual elements in your experience, without needing to rebuild components from scratch. For more information on creating your own theme, see [Create a custom theme](#).

When you define theme variables in the [sys_ux_theme] table, you can use them directly in the UI Builder Styles CSS editor to add styling to your pages. For more information about working with theme variables in the CSS styles editor, see [Themes in UI Builder](#).

**Procedure**

1. Navigate to **Now Experience Framework > UI Builder**.

2. To select an experience that you want to build, do one of the following:
   - Select an experience from the list.
   - Select + **Create experience in Platform** to create a new experience, and then add it to the list.
   The UI Builder environment appears.

3. Make sure that your selected application scope is the same scope that your experience is associated with.
   To change your application scope, do the following:
a. In the main header, select the application picker ( ),
b. Select the appropriate application scope.

4. In the UI Builder main header, select **Menu > Edit experience settings**. The Experience Settings screen appears.

5. From the settings menu, select **Branding and theming**.

6. From the Themes list, select the theme that you want to apply to all pages in your experience.
   The following themes are available for you to select:
   - Default: The default ServiceNow theme.
   - Base Agent Workspace theme: The default theme for a Workspace experience.
   - If you want to create a new theme, select **Create a theme**. See **Create a custom theme**.

7. After selecting a theme to apply, select **Save all changes**.

8. **Optional**: To view your theming changes, select **Open** in the URL header.

## Data resources in UI Builder

You can bind data to your page by using data resources to dynamically expose your data from the tables and records on your page. You then bind these data properties to the components on your page so that you can reuse your components in User Interface (UI) Builder.
Learning about data resources

A data resource is the data that a page fetches to display the content in the components. The components use these data resources as a way to reuse the data and configurations across different experiences. Data resources make the components dynamic on a page, which means that you don’t have to create a component for every page.

You can bind the configuration properties for components, other data resources, client scripts, client state, and events to these data resources.

Set conditions for a filter in your data resource. For more information, see Connect data to your components.

How data resources work

The data resources fetch the data from Glide, GraphQL, as well as the REST APIs. The data resources then update the data that it fetches and transforms the data for use in a component on a page.

Both inherited data resource instances and local data resource instances are used in components. The inherited data resources are automatically brought in through your page. The local data resource instances enable you to add and configure additional data resources. You can also specify when the resources get evaluated and supply the input values so that the data resources know how to get the right data. For more information about inherited and local data resources, see Inherited versus local data resources.

Local data resources

You can choose local data resources, such as the server data, operations, transforms, or client data, like the gForm API, to bring your own data to your page.

The data resources are organized by the application that owns them. They are then further organized by the data resource type like Server data or Transform. For example, the Global application has several data resources but the Customer Service Management (CSM) Workspace application has only a few data resources.
You see different data resources depending on the application that you are in. If you select the Global application, you see different data resources under Server data than if you had selected the CSM Configurable Workspace application and Server data.

The following table shows the data resources that are available for the Global application.

### Global data resources

<table>
<thead>
<tr>
<th>Data resource</th>
<th>Definition</th>
</tr>
</thead>
</table>
| Server data   | Server data resources that grab data from a server. They include:  
  - Aggregation Query  
  - Build route map  
  - Canvas_User_Session_DB_GQL  
  - Dynamic Routing  
  - EVAM Data Resource  
  - Fetch EVAM Data  
  - Fetch EVAM Metadata |
<table>
<thead>
<tr>
<th>Data resource</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Filtered Incidents</td>
</tr>
<tr>
<td></td>
<td>• GlideRecord Collection Query</td>
</tr>
<tr>
<td></td>
<td>• GlideRecord Query</td>
</tr>
<tr>
<td></td>
<td>• Look Up Properties</td>
</tr>
<tr>
<td></td>
<td>• Look Up Records</td>
</tr>
<tr>
<td></td>
<td>• Look Up Users</td>
</tr>
<tr>
<td></td>
<td>• Look Up User Preferences</td>
</tr>
<tr>
<td></td>
<td>• Search EVAM Data Resource</td>
</tr>
<tr>
<td></td>
<td>• Table route map</td>
</tr>
</tbody>
</table>

**Operations**

Operations data resources that let you perform actions. They include:

- Create Record
- Delete Multiple Records
- Delete Record
- Update Multiple Records
- Update Record

**Transform**

Transform data resources that let you perform transforms. They include:

- Bind data to component prop
- Canvas_User_Session_DB_Transform
- Data Driven Items
- Data Driven Tabs Transform
- Get Incident Caller Greetings
- Now DateTime
- Substitute Query Variables

**Client data**

Client data resources that include:

- Service Catalog Glide Form
Using data binding

You can use data binding to bind properties to static components to make a dynamic page. When you first add a component to a page, it is static, which means that it doesn't perform any action. You add data resources to fetch data from the back end of your instance to connect a component to data. For example, a Content tree component doesn't show any data until you bind it to a data resource that pulls in the content. You use field parameters to get data resource properties from the URL, like a table name or sys_id.

You can bind data to a component in the following ways:

Context binding. Use required or optional URL parameters to bind context property fields in the URL. For example, you bind the table name from the URL into your component by using @context syntax, such as @context.props.table.

For example, let's say that your page has a required field on it called table. The URL that resolves to your page would then be something like /demo/page/<table-name>. The <table-name> could be incident. Data could also come from the parent data resources or be local page properties that don't map to anything. You bind component properties, other data resource properties, or event payload properties to the page property with a @context.props.table context binding. If you are using a context binding, make sure that you have supplied a test value on the URL or a static value for that property in the body configuration of your page.

Data resource binding. Add data resources to fetch data from the back end of your instance, such as Client state, GraphQL, or a REST API. Data resources expose properties that you can bind to components and elements on a page.

For example, let's say that you have a Lookup Record data resource. In a button component, you could use a data expression in the label prop like @data.lookup_record_1.result.number.displayValue.

Component binding. Use component binding to bind one component to another. Let's say that you have a List Menu component on the page. It exposes the currently selected list to other components on the page. Other components could get the data by binding to it with an expression such as @elements.list_menu_1.selectedListId.
Client state parameter binding. Use `@state` syntax to bind a state property to a client state parameter.

**Types of data sources available in UI Builder**
You can use the following data resource types that are shown in the table.

<table>
<thead>
<tr>
<th>Data resource type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GraphQL</td>
<td>GraphQL queries and mutations that are executed.</td>
</tr>
<tr>
<td>Transform</td>
<td>Script that transforms the input data into another format.</td>
</tr>
<tr>
<td>Client state</td>
<td>Client-side data resources that include the client information, domain-specific states or logic, user preferences, and so on.</td>
</tr>
<tr>
<td>Composite</td>
<td>Single reusable data resource that contains multiple data resources.</td>
</tr>
<tr>
<td>REST</td>
<td>Data resources that are made through REST API requests.</td>
</tr>
</tbody>
</table>

**Inherited versus local data resources**
Inherited data resources come from the parent page or pages that surround your current page. For example, there may be data resources coming from the application shell of your UX application or data resources from the page surrounding a tab set. Inherited data resources are available for you to use and expose to your page by binding to them in the body properties for your page and mapping them to local page (context) properties. You do not need to add your own data resource if the data you need is already being supplied through inheritance.

Local data resource instances are data resources that you add to the page. Think of local data resources as specific data resources that you add yourself. You expose local data resources to a component on a page.

For example, if you are creating a travel request page, you can expose employee records to a list component. Employees can then create travel requests that are associated with their own employee data.
You can add a data resource from an application or you can create a local data resource in ServiceNow platform Lists and Forms. You then use UI Builder to expose that data for the components on your page.

Once the data is available to your page, bind the data to your component so that the component can use the data. For example, you can create a data resource for a set of records. You then expose that set of records in UI Builder. Finally, you bind that set of records to a component. You then configure the component to perform an action on that data, such as save a new record.

**Data resource properties**

Data resource properties can be thought of as how the data resource fetches the data. The properties of a data resource get exposed when you add the data resource to UI Builder. The properties define everything about the data resource. For example, the properties of a data resource could be the tables, conditions, how to order them, and so on.

**Data resource scripts**

When you add a data resource to your page, you see a preview of the outputs of that data resource if all the required properties have been configured. The output preview is a good way to see how the data gets retrieved so that you can quickly determine if the data you need is present.

**Next steps**

Connect data to your components

Define and bind client scripts to components

Create and bind a client state parameter to a component

**Connect data to your components**

Add data resources so that you can dynamically expose your data from tables, records, or other elements on your page in User Interface (UI) Builder. You can bind that exposed data to components on your page and later reuse those components elsewhere.

**Before you begin**

Role required: ui_builder_admin

**Procedure**

1. Navigate to Now Experience Framework > UI Builder.
2. Open an experience to work in or create a new experience by selecting Create experience in Platform.
For more information, see Create an experience for UI Builder.

3. Create or open a page.

4. Add a component to your page, such as a button.
   You need a component on your page before you can bind a data resource to it.

5. From the lower-left pane, select Data.
   In the Data resource instances section, you can add and configure data resource instances for your page. If you have any inherited data resources, you see them listed in the inherited data resource pane but they are read-only. You do not configure inherited data in UI Builder.

6. To add a data resource to your page, select + Add.

7. Choose an application to select a data resource from.
   The Global application contains the most common data resources. The data resources relate to Server data, Operations, and Transform. You can add a data resource such as Look Up Records, Table route map, GlideRecord Query, and so on.

8. Select a data resource to add to your page.
   For example, under Server data, you could select Lookup Record. Select Add to add it to your page.

9. Click the Configurations tab to configure the data resource and then do the following actions:

   a. From the When to evaluate this data resource list, select when you want to evoke the data resource.

   b. To set the conditions for a filter for your data resource, click Edit incident filter.
For more information about using the condition builder, see Condition builder.

10. To set up an event handler for your component, click + Add a new event handler.
   The following example shows how to add an event handler for a button component.

11. From the Event handler preview section, select an event handler to bind to your component.
   For more information about event handlers, see Configure an event handler.
For more information about binding an event to a component, see Bind an event to a component.

12. **Configure the event handler and click Add.**
You configure each event handler differently, depending on the action of the event. For example, if you add an event handler for a button component, you can choose what that button action performs.
For more information about binding an event to a component, see Bind an event to a component.

**Define and bind client scripts to components**
Add and edit client scripts in User Interface (UI) Builder so that you can update the client state through events. You can bind these scripts to any component by using an event handler.

**Before you begin**
Role required: ui_builder_admin

**About this task**
You can create JavaScript client scripts in UI Builder by using the Now Code editor. Then, you can add the client script as an event handler to update the client state, emit a handled event of your page, or execute a data resource
operation. For example, you could write a script to increment a date or counter, and bind the script to a component event, like a button click. For more information about the Now Code Editor, see Now Code Editor.

With these scripts, you can do the following actions:

• Get available data, manipulate the data, and store it in the client state.
• Access data resource results.
• Execute data resource operations.
• Dispatch events.

Procedure

1. Navigate to Now experience framework > UI Builder.

2. Open an experience to work in or create a new experience by clicking Create experience in Platform.
   For more information, see Create an experience for UI Builder.

3. Open or create a page.
   For more information, see Work with pages.

4. Optional: If you do not have any components on your page, add a component to your page.
   For example, you can add a Heading component. For more information, see Add and configure components.

5. In the lower-left panel, click the Client Scripts icon, and then click the Add.
6. Write your script to perform an action.
   For example, you could write a simple date script that you bind to a component.

7. Name your script.
   A descriptive name helps you know what the script does. It also makes it easier to find the script later when you add it to an event handler. The following example shows a simple date client script.

8. Optional: Add a **Script include** or **Associated components**, which will show up in the **imports** parameter of your client script function.

9. Select the component on your page that you want to bind the script to and then click **Events**.

10. Click **+Add a new event handler**, select the script that you created under Scripts, and then click **Add**.
    The following example shows a date client script.
11. Click **Save**.

12. To preview your scripted component, click **Open**.

Create and bind a client state parameter to a component

Create and bind a client state parameter value to a component in User Interface (UI) Builder. By adding custom values to your components, these components can then be automatically updated through a script.

**Before you begin**
Role required: ui_builder_admin

**About this task**
You can add two components to a page and then connect them by using client state parameters and scripts. Start by creating a client state parameter and then binding the client state parameter to one of the components, such as a label. Next, you create a client script and bind it to a second component, such as a button, using an event handler. When you create the event handler, bind the client state parameter value to it to connect the two components. If you click one component, it changes the state of the other component. Client
states are useful because you can add custom values to your components that can be automatically updated through a script. Think of a client state as a bucket for storing information that is specific to the page.

For example, you can add a button and label component to your page. The button changes the value of the label, such as changing the text color.

**Procedure**

1. Navigate to **Now Experience Framework > UI Builder**.

2. Open an experience to work in or create a new experience by selecting **Create experience in Platform**.
   For more information, see **Create an experience**.

3. Create or open a page.
   For more information, see **Work with pages**.

4. Add two components to your page.
   For more information, see **Add and configure components**.

5. To define a client state parameter that has a value that is associated with it, click the Client state icon in the lower-left panel, and click +Add.

6. Enter a name for the client state, a type, and an initial value.
   The client state supports Strings, Numbers, Boolean, and JSON. For example, you could enter the name as `dynamic_label_value`, the type as `String`, and the initial value as `Initial Value`. 
7. Bind the value of the client state parameter to your component.
   a. Select the component you want to bind the client state parameter to.
   b. Click the Config panel and in the Value field, start typing @state and auto-complete lists the available client state parameters.
   c. Select the client state parameter you created from the list.
   d. In the ongoing dynamic_label_value example, you are using in this task, in the Value field, you would enter @state, and select @state.dynamic_label_value from the list.

8. Click Save, and select Open.

9. Bind the client state value to one component and create a script to connect the second component to the first.
   a. In the left pane, click the script icon.
   b. Click the +Add icon.
   c. Enter a script name that describes the task. For example, you could enter Update Label Value because that is what you want the script to do.
   d. In the Now Code Editor, add your script. Let’s say that you choose an API to call, and the parameters for the API, such as a state and a value. For example, you could call the api.setState, and include the
dynamic_label_value as the first parameter, and a NEW VALUE as the second parameter.

```javascript
/**
 * @param {params} params
 * @param {api} params.api
 * @param {any} params.event
 * @param {any} params.imports
 */
function handler({api, event, helpers, imports}) {
  api.setState('dynamic_label_value', 'NEW VALUE')
}
```

10. Add an event handler to your second component to call the new client script that you created.

   a. Select the component on your page that you want to bind the script to.

   b. Click the Events tab.

   c. Click + Add a new event handler.

   d. Under the Scripts section of event handlers, select the script that you created, and click the + Add icon to add it as an event handler for the component.

11. Save your page.
12. To preview your page and test the components to ensure they are connected, select Open.
When you select one component, it should change the state of the second component. For example, click the Button component to change the Label value component text from Initial Value to NEW VALUE.

Results
What you did in this procedure:

• Added two components to your page.
• Defined a client state parameter that had an initial value.
• Bound the client state parameter to the first component.
• Created a client script that updates a value that is defined by the client state parameter.
• Created an event handler for the second component to call the new client script that you just created.
• Selected the second component so that it changed the state of the first component.

Entity View Action Mapper for UI Builder
With User Interface (UI) Builder, you can use the Entity View Action Mapper (EVAM) application to standardize how the data sources in your components are displayed in your cards and lists.

EVAM Overview
Entity View Action Mapper (EVAM) is an application that standardizes how different data sources are displayed in cards and lists. UI Builder uses EVAM data sources to show information in a component as a card grid view or as a list of information. You can add a toggle to your component to let users switch between card grid and list views.

EVAM consists of the following components:

• Entity (data source). Associated data that you intend to display, such as a community post or a user.
• View. How a card displays data and actions.
• Actions. Action that it performs on the card. For example, you can activate a user into your system.
• Map. A process that maps the data source to generic fields that are displayed on the card. You can also associate actions that trigger from the card view.
**EVAM data sources**
You add EVAM data sources in UI Builder and bind them to a component.

### EVAM data resources

## Add an Entity View Action Mapper data resource to a page

Add an Entity View Action Mapper (EVAM) data resource to your page in Now® Experience UI Builder so that you can standardize how the data sources in your components are displayed in your cards and lists.

### Before you begin

Role required: ui_builder_admin

### Procedure

1. Navigate to **Now experience framework** > **UI Builder**.
2. Open an experience to work in or create a new experience by selecting **Create experience in Platform**. For more information, see **Create an experience**.
3. Open or create a page. For more information, see **Work with pages**.
4. Optional: If you do not have any components on your page, add a **Data set** component to your page. For more information, see **Add and configure components**.

### EVAM data sources (continued)

<table>
<thead>
<tr>
<th>EVAM data source</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add an Entity View Action Mapper data resource to a page</td>
<td>Add an Entity View Action Mapper (EVAM) data resource to your page in Now® Experience UI Builder so that you can standardize how the data sources in your components are displayed in your cards and lists.</td>
</tr>
<tr>
<td><strong>Before you begin</strong></td>

</tr>
<tr>
<td></td>
<td>• Pagination Token: In the <strong>Pagination Token</strong> field, add a pagination token if needed.</td>
</tr>
</tbody>
</table>

To add an event handler for when that data fetch is initiated, succeeded, or failed, select **Events**.

Preview the EVAM definition script in the **Now Code Editor** to the right of the Configuration pane.
9. Configure your data set component:
   
   a. Bind an EVAM data resource to your component.
   
   b. Set the Show grid/list toggle to on to let users choose between the grid or list view of the EVAM information on the page.
   
   c. Set the other configuration settings for the cards on the page.

10. Click Save.

11. To preview your component with the EVAM data resources, click Open.
Finished state of the EVAM

What to do next
For more information, see the following EVAM topics:

- Entity View Action Mapper
- Getting started: Create a multi-data source list display in Entity View Action Mapper
- Create an EVAM action definition
- Create an EVAM definition

Events in UI Builder
Learn how to work with events so that you can add actions to components, pages, data resources, and declarative actions in User Interface (UI) Builder.

Event mapping
An event mapping is the process that enables you to map an event’s payload or contextual values to the object or handler that acts on that event.

For more information about event mapping, see Event mapping.

Events
Use an event to add actions to your components, pages, and data resources.
• A component event is an action that you set up for a component. You set up an event handler to configure that component action. For example, you can add a button component to your page. Then, you can add an event handler to apply an action for that button, such as going to a web page.

• Page events perform actions for the entire page. You can configure the following page events:
  ◦ Page event mappings. Add, remove, or clear alert notifications on your page.
  ◦ Variant event mappings. Add, remove, or clear alert notifications on your page variant.
  ◦ Dispatched events. Create dispatched events for your page to create relayed event mappings that model events after a parent event handler. Select a target parent event handler to model the payload fields after it.
  ◦ Handled events. A handled event is an event that is exposed and available for use by other users. After you create a handled event, it is available under Page event mappings for other users to use. You can also set up payload fields that you create manually or choose a template for your handled event, such as an open or close a modal dialog.

• Data resources events map data resources to notify information about when data is fetched.

Event handlers

Use an event handler to configure an action for your page or the components on the page. For example, you can map an event to your page to add an alert notification when the page successfully loads. The alert notification shows as a modal on the page that asks a user to verify that the user wants to delete the record.

When you add an event handler to a page or component, you can choose different types of event handlers. For example, a Button component can have the following types of event handlers:

• Inherited event handlers. An inherited event handler is exposed from the page that you are working in. If you are in the parent page, an inherited event handler could be exposed from the app shell. The following table lists the different types of inherited event handlers that you can use and what you can do with them.
Inherited event handlers

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Link to destination</td>
<td>Navigate to a destination.</td>
</tr>
<tr>
<td>◦ App routes: Link to another page within an app, like a home screen.</td>
<td></td>
</tr>
<tr>
<td>◦ External URL: Link to a website or any external URL.</td>
<td></td>
</tr>
<tr>
<td>Add parameters to URL</td>
<td>Add additional parameters to a URL.</td>
</tr>
<tr>
<td>Open or close modal dialog</td>
<td>After you create a modal, use Open or close modal dialog to trigger the modal.</td>
</tr>
</tbody>
</table>

Page-level event handlers. This type of event handler is common to all pages, and you would use this handler type when you want to add or clear page-level alert notifications. The following table lists the different types of page-level event handlers that you can use and what you can do with them.

<table>
<thead>
<tr>
<th>Event handler</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add alert notifications</td>
<td>Add a code snippet to send an alert notification. For example:</td>
</tr>
<tr>
<td></td>
<td>[{&quot;content&quot;: &quot;hello world&quot;}]</td>
</tr>
<tr>
<td>Remove alert notification</td>
<td>Add code to call alert notification IDs that you want to dismiss. For example, click a button to remove a page load alert notification.</td>
</tr>
<tr>
<td>Clear alert notification</td>
<td>Add code to call all alert notification IDs that you want to dismiss. For example, click a button to remove all alert notifications.</td>
</tr>
<tr>
<td>Set loading state</td>
<td>Toggle loading on or off. For example, you can toggle loading on to load the page when you click a button or toggle loading off to not load the page when a button is clicked.</td>
</tr>
</tbody>
</table>
### Event handler | Description
--- | ---
Update client state parameter | Declaratively set the client state parameter. Let's say that you have a client state parameter that you set up with a value. You can configure the **Update client state parameter** event handler to update the client state parameter with a new value. For example, you have a client state parameter that is called **Greeting** that is set up with **Hello** as the initial value. You can add an **Update client state parameter** event handler select the **Greeting** client state parameter, and then enter a new value like **Goodbye**. When you click the button, **Goodbye** replaces **Hello** on the page.

- Data resource handlers. This type of event handler triggers the fetching or writing of data to the server. You can refresh the app shell data source data on your page by clicking a button. For example, with a data resource handler, you can do the following actions:
  - Bind data to the description of an incident record.
  - Change the value of the incident description.
  - Add a button component to your page.
  - Label the button as **Refresh incident**.
  - Add a **Look Up Record** event handler for the button.
  - Save your page.
  - If the description of the incident record changes, click **Refresh** to update the description on your page.

- Client scripts. Scripts that execute when an event is triggered on a component. You create these scripts in the Client scripts section in UI Builder. For more information, see **Define client scripts**.

#### Binding events to components

Bind event handlers to the events on a component. When you add components to your page, these components are not configured to perform any action on your page. For example, a button component is static and does not do
anything until you bind an event action to it, such as deleting a record. Some components have several events where event handlers can be assigned. For example, on the list component, you can assign a navigation handler to the Row clicked event. You can also assign an open modal to the Data fetch failed event. For more information, see Bind event to a component.

**Binding events to pages**

Bind a page-level event to execute event handlers on the page. For example, use page-level events for page notifications, page load, or when a page property changes. The assignment of the event handler to the page-level event is similar to assigning handlers to events from components.

You can bind event mappings using the following methods:

- Page event mappings. Add, remove, or clear alert notifications on your page.
- Variant event mappings. Add, remove, or clear alert notifications on your page variant.
- Dispatched events. Create dispatched events for your page to create relayed event mappings that model events after a parent event handler. Select a target parent event handler to model the payload fields after it.
- Handled events. Add a handled event for an event that is exposed and available for use by other users.

For more information, see Bind event to page.

**Binding events to data resources**

Bind event handlers to individual data resources on your page. For example, when a data resource successfully fetches new data, it executes an event handler, like navigation, to take a user to the next step in a flow. When a data resource successfully adds a record to a table, it shows a success modal that uses the show modal event handler. For more information, see Bind event to data resources.

**Binding events to declarative actions**

Bind data elements to add event actions to a declarative action definition in Actions & Components in the Now Platform®. For example, you could bind a data element to add an event action to complete work on a table.

If you add a component to your page that has a declarative action, you must bind it to a handled event. The handled event creates an action that is performed when a user selects the component. By selecting Configure declarative action event mapping, you add a new event handler to define what the declarative action does on the page.
Event mapping

An event mapping in User Interface (UI) Builder is the process that enables you to map an event's payload or contextual values to the object or handler that acts on that event. The four event types are component, page, data resource, and declarative action.

Event mapping is an important process within UI Builder. When you build pages with components, you need those components to perform actions for users. For example, if you add a button component to the page, a button-clicked event must be mapped to an event handler. The event handler performs a button-clicked action when it is selected by a user. An example is when you add a data resource, such as a form, and have an event handler notify the user when the form successfully loads.

Event types

The event types that are available are based on the component. For example, declarative action events are available for specific components, such as the Action bar or List components.

You choose a type of event based on what action you want to perform on your page. For example, if you want to bind an action to a component, such as a button loading a web page, you would use a component event. If you want an event to apply to your whole page, such as adding an alert notification to a page, you use a page event. The following table describes each event type
that is available in UI Builder and provides some examples on how you can use the events.

### Event types and descriptions

<table>
<thead>
<tr>
<th>Event type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component events</td>
<td>Action that you set up for a component. You set up an event handler to configure that component action. The following example shows how to add an event handler to apply an action for a button, such as going to a web page. For more information on binding events to components, see <a href="#">Bind an event to a component</a>.</td>
</tr>
<tr>
<td>Page events</td>
<td>Page event that performs an action for the entire page. You can configure the following page events:</td>
</tr>
<tr>
<td></td>
<td>• Page event mappings.</td>
</tr>
<tr>
<td></td>
<td>◦ These event mappings are saved on the page definition record, which can be found in the [sys_ux_macroponent] table.</td>
</tr>
<tr>
<td></td>
<td>◦ The source events for these event mappings are Page ready and Page property. They are defined for your page.</td>
</tr>
<tr>
<td></td>
<td>◦ The available handlers for these event mappings are as follows:</td>
</tr>
<tr>
<td></td>
<td>■ User session events</td>
</tr>
<tr>
<td></td>
<td>■ Page-level events</td>
</tr>
<tr>
<td></td>
<td>■ UXR App Shell Data Source</td>
</tr>
<tr>
<td></td>
<td>■ Client scripts that are defined on the page</td>
</tr>
<tr>
<td></td>
<td>■ Operations from local and inherited data resources</td>
</tr>
<tr>
<td></td>
<td>• Variant event mappings.</td>
</tr>
<tr>
<td>Event type</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>◦ These event mappings are saved on the variant record, which you can find in the [sys_ux_screen] table.</td>
<td></td>
</tr>
<tr>
<td>◦ The source events for these event mappings are any dispatched events that are defined for your page.</td>
<td></td>
</tr>
<tr>
<td>◦ The available handlers for these event mappings are canvas-level events, the UXR App Shell Data Source, and operations from the inherited data resources.</td>
<td></td>
</tr>
<tr>
<td>◦ Variant event mappings are used as relays so that the events that are dispatched from components on your page can be relayed up to user session event handlers.</td>
<td></td>
</tr>
<tr>
<td>◦ Mappings are created automatically on a page save when you have mapped a component's dispatched event to a user session handler. For example, by mapping a <strong>Button clicked</strong> event to the canvas-level <strong>Link to destination</strong> event, the event creates a dispatched relay event and a variant event mapping when the page is saved.</td>
<td></td>
</tr>
</tbody>
</table>

• Dispatched events.

| ◦ These events are saved in the [sys_ux_event] table. The page definition record contains references to the [sys_ux_event] record. |
## Event types and descriptions (continued)

<table>
<thead>
<tr>
<th>Event type</th>
<th>Description</th>
</tr>
</thead>
</table>
| ◦ These events serve as source events for variant event mappings.  
◦ You can select **+Add** to create new dispatched events for your page. Configure the event label to auto-populate the event name and payload fields for your new `sys_ux_event`.  
◦ These events are used to create relay event mappings. You can select a **Target parent event handler** to model the payload fields after the selected event. You can also manually create payload fields for your dispatched event. |  
• Handled events.  
◦ These events are saved in the `[sys_ux_event]` table. The page definition record contains references to the `[sys_ux_event]` record.  
◦ These events serve as source events for page event mappings.  
◦ You can select **+Add** to create new dispatched events for your page. Handled events are not modeled after parent event handlers. Payload fields for handled events are created manually. To use an existing handler's payload fields as a template, select a template and edit the fields as necessary. |
## Event types and descriptions (continued)

</thead>
<tbody>
<tr>
<td>Data resource events</td>
<td>Events that are mapped to data resources to provide notifications about when data is fetched.</td>
</tr>
<tr>
<td></td>
<td>• Data Fetch Initiated. When a data resource event is triggered, the event handler executes the data fetch process.</td>
</tr>
<tr>
<td></td>
<td>• Data Fetch Succeeded. When a data resource event is triggered, the event handler executes the process</td>
</tr>
</tbody>
</table>

For more information on binding an event to a page, see [Bind event to page](#).
<table>
<thead>
<tr>
<th>Event type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Fetch Initiated</td>
<td>to notify a user when the data fetch completed successfully.</td>
</tr>
<tr>
<td>Data Fetch Succeeded</td>
<td>• Data Fetch Failed. When a data resource event is triggered, the event handler executes the process to notify a user if the data fetch was unsuccessful.</td>
</tr>
</tbody>
</table>

For more information on binding an event to a data resource, see Bind event to data resource.

### Declarative action events

Bind data elements within UI Builder to add event actions to a declarative action.

You configure a declarative action event mapping in the Now Platform® declarative action assignment table. For an example, navigate to Filter navigator > sys_declarative_action_assignment.list and then search for and open an existing declarative action.

In UI Builder, you bind an event to the declarative action. For more information on how to use declarative event actions, see Bind event to data resource.
### Event types and descriptions (continued)

<table>
<thead>
<tr>
<th>Event type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action events, see Bind event to declarative action.</td>
<td>action events, see Bind event to declarative action.</td>
</tr>
</tbody>
</table>
a. Select the component to highlight it, either in the content tree or on the page itself.

b. From the Content section, click +Add.

c. Select Modal, and choose a modal type, such as Confirm.

d. Configure the modal. You can change the text in the modal, the names of the buttons in the modal, and the size of the modal screen. You can also set actions for the modal. When you finish configuring the modal, close it. Notice the modal that you created sits above the body of your page structure in the Content tree.

6. To add an event handler to your component’s event, go to the Configuration pane and select Events. An event handler lets you assign an event to a component. For example, if you add a button component to your page, you want it to perform an action when a user clicks it.

7. To start the process of assigning the event to the component, choose an event that is associated with a component, and then click Add a new event handler. For example, a button component only has the Button clicked event that is associated with it. Other components can have many events.
8. From the Event handler preview screen, select an action that you want assigned to the component. For example, to add an event handler for the button component, you could link it to another destination.

9. Click the Open or close modal dialog event handler.
   a. Click the Confirm modal dialog that you created earlier.
   b. Select the Open modal dialog selector so that the modal opens when a user clicks the button component.
   c. To add the modal event handler to your component, click Add.

10. Click Save.

### Bind an event to a component

Bind data elements within User Interface (UI) Builder so that you can add event actions to your components. Each component has specific events that it binds to. For example, a button component has only a button-clicked event, while other components can have multiple events that are associated with them.

#### Before you begin
Role required: ui_builder_admin

#### About this task
Some components do not have an event action that is applied to them. An example is the heading component. Many components require that you map an event to your component to make it perform an action, such as loading data.

To add actions to components, pages, and data resources on your page, you can add an event handler. A button component that you add to a page is static. By binding an event action to the button, you can link it to a web page.

#### Procedure
1. Navigate to Now Experience Framework > UI Builder.
2. Open an experience to work in or create a new experience by selecting Create experience in Platform.
For more information, see Create an experience.

3. Create or open a page.

4. Add a component to your page, such as a button.

5. To add an event handler to your component, select the Events tab.
   For more information on how to add event handlers to your component, see Work with events.

a. To start the process of setting up an event handler for your component, click + Add a new event handler.
   The following example shows how to add an event handler for a button component.

   ![Events tab preview]

   b. From the Event handler preview section, select an event handler to bind to your component.

   ![Event handler preview]
c. Configure the event handler and click **Add** when finished.
   You configure each event handler differently, depending on the action of the event. For example, if you add an event handler for a button component, you can choose what that button action performs.

6. **Optional:** If you want a modal to pop up for your event, add the modal to the component before you bind your event to the component.
   A modal is a confirmation pop-up that appears when you click the component. For example, if you add a button component that deletes a record, you add a modal to ask the user to confirm that the user wants to delete the record. For more information, see **Add modal to component**.

a. Select the component to highlight it, either in the content tree or on the page.

b. From the content section, click **+ Add**.

c. Click **Modal**, and choose a modal type, such as Confirm and destroy.

![Modal types](image)

d. Configure the modal.
   You can change the text in the modal, the names of the buttons in the modal, and the size of the modal screen. You can also set actions for the modal. When you finish configuring the modal, close it. Notice that the modal you created sits above the body of your page structure in the content tree.

7. **Bind an event to your component.**
   You bind an event to the button to trigger an action. Select the button component to highlight it again, either in the content tree, or on the page.

8. In the Configuration pane, click **Events**.

9. To start the process of binding an event to the button component, select **Add a new event handler**.
The button component only has the button-clicked event associated with it. Other components can have more than one event.

10. Select an action that you want assigned to the component. For example, to add an event handler for the button component, you could link it to another destination and add alert notifications. In this example, you can choose **Open or close modal dialog** to make the button open the modal that you created earlier.

![Modal Dialog Configuration](image)

11. In this button scenario, select the Confirm and destroy modal dialog event handler that you created earlier.

   a. Turn on the **Open modal dialog** selector so that the modal opens when a user clicks the button component.

   b. To add the modal event handler to your component, click **Add**.

12. Click **Save**.

13. To preview your work, click **Open**.

![Modal Dialog Preview](image)

14. To trigger the confirmation modal that you created, click the button on the page.

15. Click **Save**.

16. To preview your page and test the component event, click **Open**.

![Modal Dialog Preview](image)

**Link an event to another page**

Add a link to the destination event handler within User Interface (UI) Builder so that an event action can open another page. You can also configure the event handler to follow the App Route to the desired page.
Before you begin
You must have a workspace page that contains a component that is intended
to open another page when a user clicks it. The dashboard overview is an
example of such a component.
Role required: ui_builder_admin

About this task
To configure an event action to open another page, you must know what page
you want to open, the required and optional parameters are for that page,
and what payload values to set on the event handler to pass the required
parameters to the destination page.

Tip: You may be able to find examples of both the components that you
want to link from and the destination pages that you want to link to in the
Base Agent Workspace Experience. This Now® Experience is provided in
the base system. If you create a page from a page template, you should
only copy the contents of the template. Do not reference it. For more
information about the difference between copying and referencing a
page template, see Page templates.

Procedure
1. Open your experience in Now® Experience UI Builder.

2. Optional: If the destination page doesn’t exist in your experience, create one.
For information about creating pages, see Create a page in UI Builder. Make
sure that you set the required and optional parameters for the page so that
you can use it as a destination. If a particular component in the page is a
destination, you need to include that component. You also need to configure
the properties on the component to consume the page parameters with
@context.props.<parameter-name> values.

You might consider creating the page from a page template. The Base
Agent Workspace Experience has several page templates that are already
configured to be destinations for other components. If you create a
destination page from a template, the components are already configured
with the correct properties. Any necessary state parameters or client scripts
are also copied over. You have to add the page parameters. You can copy
these parameters from the UX App Routes related list on the Agent app
config [sys_ux_app_config] record of the experience that contains the page
templates.

To make sure that the pages that you are creating work reliably as
destinations in your experience, your experience must have the same app
shell UI as the experience with the page templates.

3. Switch to the page that you want to link to the destination page.
4. Navigate to the relevant component and select it.

5. Click the Events tab.

6. Expand an event action that should open another component and click + Add a new event handler.

7. In the Inherited event handlers section, Click **Link to destination**.

   Event handler preview: On, Report Visualization Clicked → Link to destination (UXR Blank AppShell) → Enter values below...

   ![Event handler preview image]

   - **Search**
   - **Inherited event handlers**
     - **Link to destination**
     - Add parameters to URL
     - Open or close modal dialog
   - **Page-level event handlers**
     - Add alert notifications
     - Remove alert notifications
     - Clear alert notifications
     - Set loading state
     - Update client state parameter
   - **UXR App Shell Data Source 1**
     - Refresh
   - **Canvas User Session Data Resource GraphQL**

   ![Select destination dialog]

   **Select destination**
   - Remove previous URL from browser history
   - Load in background (advanced)
   - Title (advanced)
   - Multi-instance field (advanced)
   - Sub-navigation route (advanced)

8. Click **Select destination**.

9. Expand **App routes** and select the route to the page in the experience that you want to link to.

   Fields appear for each of the parameters on the destination page that the route leads to. Required parameters are marked with an asterisk (*).
10. Complete each required parameter field and the applicable optional parameter fields with an appropriate `@payload.*` value.
If the developers of your component included default payload values in your event, you can select one through autocompletion. As shown in the following example, the payload value may not match the parameter name.
If no default values are provided, or you can't determine which values are correct for some fields, refer to the configuration and API documentation for the component in the ServiceNow® Developer Site. If you still can't find the necessary @payload.* values, contact Customer Service and Support.

Tip: If you create your linking component by creating a page from a Base Agent Workspace page template, the component contains Link to destination Relay event handlers. These event handlers do not work. However, they contain the applicable @payload.* values for the parameters.

Example: Configuring the event handlers for an Analytics Q&A component

Let's say that you want to take a new Now® Experience and add a page with an Analytics Q&A component. First, you create the page from the Analytics Center page template that is provided in the Base Agent Workspace experience. Next, you create a target page for the first of the three events in Analytics Q&A and then you configure an event handler for that event.

By navigating to Now Experiences Framework > Experiences, you see the Test experience UX application. Because it uses the same Agent Workspace App.
Shell UI as the Base Agent Workspace, you can use the page templates from the Base Agent Workspace.

You next select the Test workspace admin panel, find an UX App Configuration record with no UX app routes or pages, and then click **Open**.

As the example shows, in the UI Builder, you have created a page named Analytics Center that is based on the Analytics Center page template from the Base Agent Workspace. Next, you select the option to copy only the contents of the page template.
You select the Analytics Q&A 1 component and open the Events tab. From here, you can open the Link to destination Relay event handler for the Report Visualization Clicked event. When a question in Analytics Q&A returns a report, you can trigger this event by clicking a value in the report. When you click a value, you also see a list of the records that contribute to this value. In the Route field, you see that the destination is expected to be a page that is based on the Simple List page template. You also see the parameters of the page that the @payload.* values correspond to, and that the Title field can be populated with @payload.listTitle.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>@payload.* value</th>
</tr>
</thead>
<tbody>
<tr>
<td>table (required)</td>
<td>@payload.table</td>
</tr>
<tr>
<td>listTitle</td>
<td>@payload.listTitle</td>
</tr>
<tr>
<td>query</td>
<td>@payload.query</td>
</tr>
<tr>
<td>disableInlineEditing</td>
<td>none</td>
</tr>
</tbody>
</table>
Next, you navigate to **Menu > Create page** and create a page that is based on the Simple List template. Let's say that you name the page as Record list. You then follow a similar process as when you created the Analytics Center page. This time in the last steps of the process, you would add **table** as a required parameter and **listTitle**, **query**, and **disableInlineEditing** as optional parameters.
Because this page already contains a List component, when you open the Config tab for this component, you see that the parameters are already passed in the `@context.props.*` values.
Now, you return to the Analytics Center page. In the Report Visualization Clicked event, you add a new event handler. Next, you select the Record list page that you created and add the `@payload.*` values in the `table`, `listTitle`, and `query` fields, following the information that you got from the Link to destination Relay event handler. Predictive typing helps you to fill in these fields.
After you click **OK** and add `@payload.listTitle` as the **Title**, the event handler is done. You now delete the Link to the destination Relay event handler for this event.

The following example shows an Analytics Center page. On this page, you can enter a query for Incidents by Priority and get a report as a result. Also, by clicking a column, you trigger a Report Visualization Clicked event. The event handler enables you to see a simple list of the incidents in the report.
Before you begin
Role required: ui_builder_admin

About this task
You can bind an event to a page by using the following types of events:
• Page event mappings. Add, remove, or clear alert notifications on your page.
• Variant event mappings. Add, remove, or clear alert notifications on your page variant.
• Dispatched events. Create dispatched events for your page to create relayed event mappings that model events after a parent event handler. Select a target parent event handler to model the payload fields after it.

• Handled events. A handled event is an event that is exposed and available for use by other users. After you create a handled event, it is available under **Page event mappings** for other users to use. You can also set up payload fields that you create manually or choose a template for your handled event, such as an open or close a modal dialog.

**Procedure**

1. Navigate to **Now Experience Framework > UI Builder**.
2. Open an experience to work in or create a new experience by selecting **Create experience in Platform**. See **Create an experience** for more information.

3. Open or create a page.

4. Highlight the page body in the content tree. The body is the top-level line of the content tree. When you highlight the whole page, you can add page-level events.

5. In the configuration panel, click the **Events** tab.

6. Add an event handler in one of the following ways:

<table>
<thead>
<tr>
<th>To add this event handler</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Page ready</strong> source event:</td>
<td><strong>Page ready</strong> source event:</td>
</tr>
<tr>
<td>a. Click <strong>Add a new event handler</strong>.</td>
<td><strong>Page ready</strong> source event:</td>
</tr>
<tr>
<td>b. To add, remove, or clear alert notifications from the page, choose an event handler from <strong>Page-level event handlers</strong>. You can add, re-</td>
<td><strong>Page ready</strong> source event:</td>
</tr>
</tbody>
</table>
### To add this event handler

<table>
<thead>
<tr>
<th>Do this</th>
<th>move, or clear alert notifications on your page.</th>
</tr>
</thead>
<tbody>
<tr>
<td>c.</td>
<td>To add the event handler to your page, click <strong>Add</strong>.</td>
</tr>
</tbody>
</table>

**Page property changed** source event:

| a. | Click **Add a new event handler**. |
| b. | Choose an event handler from **Page-level event handlers**. You can add, remove, or clear alert notifications on your page. You can also choose **Set loading state** to show the word **Loading** on your page so users can see that the page is loading. You can also select **Update client state parameter** to change the client state name. |
| c. | To add the event handler to your page, click **Add**. |

### Variant event mappings

<table>
<thead>
<tr>
<th>Variant event mappings</th>
<th>You must have a variant page to perform a variant event mapping. The Variant event mappings that are available depend on the variant page. If the variant page has a list, you add event handlers for things like Row clicked, Nav item, and so on. When the variant has a Viewport, you may have different event handlers to set up.</th>
</tr>
</thead>
<tbody>
<tr>
<td>a.</td>
<td>Select <strong>Variant event mappings</strong>.</td>
</tr>
<tr>
<td>b.</td>
<td>Click <strong>Add a new event handler</strong>. For example, you can add a new event handler for <strong>Row clicked</strong>.</td>
</tr>
</tbody>
</table>
| c. | Select an event handler from the list of available Inherited event han-
To add this event handler | Do this
--- | ---
| d. To add the event handler to your variant, click **Add**.

- These event mappings are in the variant record that are found in the `sys_ux_screen` table.
- The source events for these event mappings are any dispatched events that are defined for your page.
- The available handlers for these event mappings are canvas-level events, the UXR App Shell Data Source, and operations from inherited data resources.
- These event mappings are used as relays so that events that are dispatched from components on your page are relayed up to the user session handlers.
- These mappings are automatically created on a page save when you have mapped a component’s dispatched event to another event. For example, when you map a **Button clicked** event to the **Link to destination** event, the event cre-
<table>
<thead>
<tr>
<th>To add this event handler</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ates a dispatched relay event and a variant event mapping after you save the page.</td>
</tr>
</tbody>
</table>

a. Click **Dispatched events**.
b. Click **Add**.
c. In the Create an event screen, do the following actions:
   - Type a label for your event.
   - Select a target parent event handler.
d. To add the event handler to your dispatched events, click **Add**.

e. The new event handler that you created appears in Dispatched events. The following example
<table>
<thead>
<tr>
<th>To add this event handler</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>shows how to add a Link to destination event handler.</td>
</tr>
<tr>
<td></td>
<td><img src="image" alt="Dispatched events" /></td>
</tr>
</tbody>
</table>

- These events are in the [sys_ux_event] table. The page definition record contains references to the [sys_ux_event] record.
- These events serve as source events for variant event mappings.
- To create new dispatched events for your page, click +Add. Configure the event label to auto-populate the event name and payload fields for your new sys_ux_event.
- These events are often used to create relay event mappings. You can select a Target parent event handler to model the payload fields after the selected event. You can also manually create payload fields for your dispatched event.

<table>
<thead>
<tr>
<th>Handled events</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><img src="image" alt="Dispatched events" /></td>
</tr>
</tbody>
</table>

- These events are saved in the [sys_ux_event] table. The page definition record contains references to the [sys_ux_event] record.
- These events serve as source events for Page event mappings.
- To create new dispatched events for your page, click +Add. These events are not modeled after parent event handlers. Payload fields for handled events are created.
To add this event handler

<table>
<thead>
<tr>
<th>To add this event handler</th>
<th>Do this</th>
</tr>
</thead>
<tbody>
<tr>
<td>manually. To use an existing handler's payload fields as a template, select a template and edit the fields as necessary.</td>
<td></td>
</tr>
</tbody>
</table>

7. Click **Save**.

8. To preview your page and test the data resource event that you set up, click **Open**.

---

**Bind an event to a data resource**

Assign event handlers within User Interface (UI) Builder to individual data resources on your page. When a data resource successfully fetches new data, it executes an event handler to take a user to the next step in a flow.

**Before you begin**

Role required: ui_builder_admin

**About this task**

By binding an event to a data resource, you can perform data-related actions on your page. For example, you can add a button to reload data to a page if it doesn't load the first time. You can also set up a data resource event to reload data behind the scenes of your page.

**Procedure**

1. Navigate to **Now experience framework > UI Builder**.
2. Open an experience to work in or create a new experience by selecting **Create experience in Platform**.
   For more information, see **Create an experience**.
3. Open or create a page.
   For more information, see **Work with pages**.
4. **Optional**: If you do not have any components on your page, add one to your page.
   For more information, see **Add and configure components**.
5. To add a data resource, go to the left panel, click the data icon, and then click **+Add**.
6. To add an event handler to your data resource, click the **Events** tab in the configuration of the data resource. You can add event handlers to your data resource to handle actions for Operation Initiated, Operation Succeeded, and Operation Failed.

<table>
<thead>
<tr>

<tr>
<td>🕗 Delete Record 1</td>
<td>🕗</td>
<td></td>
<td>📦</td>
</tr>
</tbody>
</table>
a. To start the process of setting up an event handler for your data resource, click + Add a new event handler.

b. From Event handler preview, select an event handler that you want to bind to your data resource.

c. Configure the event handler and click Add.

7. Click Save.

8. To preview your page and test the data resource event that you set up, click Open.

Bind an event to a declarative action

Bind data elements within User Interface (UI) Builder so that you can add event actions to a declarative action.

Before you begin
Role required: ui_builder_admin

About this task
Bind a handled event to a component so that an action is performed when a user selects the component.

Procedure
1. Navigate to Now Experience Framework > UI Builder.

2. Open an experience to work in or create a new experience by selecting Create experience in Platform.
   For more information, see Create an experience.

3. Open or create a page.

4. Add a component to your page that can have a declarative action, such as an action bar or related list.
   For more information, see Add and configure components.

5. To create a declarative action definition in a table in the Now Platform®, navigate to Workspace Experience > Actions & Components.
   Choose a table where you want the declarative action to be available in. For example, you could create a Complete my work action in an incident table or you could use an existing declarative action definition record.
6. Select the **Active** check box, and then save or update the record.

7. Return to the UI Builder.

8. To invoke a handled event for the declarative action, go to the Config panel and click **Configure declarative action event mapping**.

9. Choose the declarative action that you created earlier. To continue with the example in step 5, the declarative action could be something like **Complete my work**.

10. To define what the declarative action does on your page, click **+ Add a new event handler**.
a. Give the event handler a name. The name should describe what action you want the event handler to perform.

b. Optional: Provide a description of the event handler.

c. Choose the handled event that you want to invoke.

d. Optional: Add payload values for your event handler.

e. Click **Save**.

11. Click **Done**.

12. Click **Save**, and then click **Open**.

13. Test the declarative action on your page by clicking **Complete my work** to see if it works.

---

**Now Code Editor**

Now Code Editor is a rich-text editor like interface that supports Cascading Style Sheets (CSS), Hypertext Markup Language (HTML), JavaScript, Extensible Markup Language (XML), and JavaScript Object Notation (JSON). Use Now Code Editor to modify UI configuration, data resource configuration, styles, events, client-side and server-side scripts in Now® Experience UI Builder components.

Now Code Editor supports the following features:

- Basic editing
- Debugging
- Command palette
- Code formatting
- Syntax checking and highlighting
- Auto-suggestions
- Script macros for common code
# Basic editing

<table>
<thead>

```

doc

• Description: Inserts a comment block for describing a function or parameters.
• Output:

```javascript
/**
 * Description:
 * Parameters:
 * Returns:
 */
```

vargror

• Description: Inserts a GlideRecord query for two values with an OR condition.
• Output:

```javascript
var gr = new GlideRecord('');
var qc = gr.addQuery('field', 'value1');
qc.addOrCondition('field', 'value2');
gr.query();
while (gr.next()) {
}
```

vargr

• Description: Inserts a standard GlideRecord query for a single value.
• Output:
Web services

HTTP-based web services allow diverse applications to talk to each other. ServiceNow supports both inbound (provider) and outbound (consumer) web services.

Direct inbound web services

Inbound web services allow you to access and modify ServiceNow data using a client application.

- REST API
- Scripted REST APIs
- SOAP web service
- JSONv2 Web Service
- RSS feed generator

Exporting and converting table records into complex data types

- Exporting and converting records into complex data types

Other inbound web services

- Scripted SOAP web services

Outbound web services

Outbound web services allow you to send SOAP and REST messages to external web service providers.

- Outbound SOAP web service
- Outbound REST web service
REST API

REST (REpresentational State Transfer) is a simple stateless architecture that provides standards between computer systems on the web, making it easier for them to communicate with each other.

The Now Platform provides various REST APIs, which are active by default. These APIs provide the ability to interact with various ServiceNow functionality within your application. Such functionality includes the ability to perform create, read, update, and delete (CRUD) operations on existing tables (Table API), insert data into, retrieve information from, and run transforms against a MetricBase database (MetricBase Time Series API, and many others.

For a list of available REST APIs, see REST API reference.

Note: You can view inbound API transactions in the Transaction logs. Use a link like the one below to view the transactions for the current day:

https://<instancename>.service-now.com/syslog_transaction_list.do?
sysparm_query=sys_created_onONToday%40javascript
%3Ags.beginningOfToday()%40javascript%3Ags.endOfToday()%5Etype%3Drest

REST URI format and available parameters

ServiceNow REST APIs follow standard REST API protocol. They also provide "custom" URI and query parameters to ensure backwards compatibility and provide additional functionality such as paginating long lists of results. The following sections describe the functionality behind these custom parameters, which are all optional.

REST API versioning

ServiceNow REST API URIs may include a version number, such as /api/now/v1/table/{tableName}. Version numbers identify the endpoint version that a URI accesses. By specifying a version number in your URIs, you can ensure that future updates to the REST API do not negatively impact your integration.

URIs that do not specify a version number in the URI, such as /api/now/table/{tableName}, use the latest REST endpoint for your instance version.

Supported REST API headers

The ServiceNow REST API supports various headers. Some headers are mandatory for specific endpoints and HTTP methods.
Supported HTTP request methods

- GET
- DELETE
- HEAD
- PATCH
- POST
- PUT

**Note:** HEAD methods can be used in place of GET methods to return a response without a response body.

Data format headers

REST APIs require the `Accept` and `Content-Type` request headers for proper data formatting for requests that contain a request body or response body. POST, PUT, PATCH, and DELETE operations require you to provide both headers. GET and HEAD operations require only the `Accept` header. Failing to provide the required headers results in a 400 Bad Request error.

For most ServiceNow REST APIs these request headers support the following values:

- `Accept`: application/json, application/xml
- `Content-Type`: application/json, application/xml

For the list of specific values supported by each endpoint, refer to the REST API reference.

Other headers

All requests may contain an authentication header that specifies the user credentials to use for authentication.

You can also override HTTP methods, such as GET or POST, by setting the `X-http-method-override` header.

Custom query parameters

The ServiceNow REST APIs use the following query parameters across many of the available APIs, providing consistent behavior across the APIs. Use these parameters to paginate large record sets, filter results, and restrict the number of records returned in a single query.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the <code>sysparm_offset</code> parameter to paginate record retrieval. This limit is applied before ACL evaluation. If no records return, including records you have access to, rearrange the record order so records you have access to return first. <strong>Note:</strong> Unusually large <code>sysparm_limit</code> values can impact system performance. Data type: Number Default: 1000</td>
</tr>
<tr>
<td>sysparm_fields</td>
<td>Comma-separated list of fields to return in the response. Data type: String</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, <code>sysparm_offset</code> is set to &quot;0&quot;. To simply page through all available records, use <code>sysparm_offset=sysparm_offset+sysparm_limit</code>, until you reach the end of all records. Do not pass a negative number in the <code>sysparm_offset</code> parameter. Data type: Number Default: 0</td>
</tr>
</tbody>
</table>
| sysparm_query  | Encoded query used to filter the result set. Syntax: `sysparm_query=<col_name><operator><value>`.  
  - `<col_name>`: Name of the table column to filter against.  
  - `<operator>`: Supports the following values:  
    - `=`: Exactly matches `<value>`.  
    - `!=`: Does not match `<value>`.  
    - `^`: Logically AND multiple query statements.  
    - `^OR`: Logically OR multiple query statements. |
LIKE: `<col_name>` contains the specified string. Only works for `<col_name>` fields whose data type is string.

STARTSWITH: `<col_name>` starts with the specified string. Only works for `<col_name>` fields whose data type is string.

ENDSWITH: `<col_name>` ends with the specified string. Only works for `<col_name>` fields whose data type is string.

`<value>`: Value to match against.

All parameters are case-sensitive. Queries can contain more than one entry, such as:
```
sysparm_query=<col_name><operator><value>[<operator><col_name><operator><value>]
```
For example:
```
(sysparm_query=caller_id=javascript:gs.getUserID()^active=true)
```

Encoded queries also supports order by functionality. To sort responses based on certain fields, use the ORDERBY and ORDERBYDESC clauses in `sysparm_query`.

Syntax:
- `ORDERBY<col_name>`
- `ORDERBYDESC<col_name>`

For example:
```
sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory
```
This query filters all active records and orders the results in ascending order by number, and then in descending order by category.

If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the property `glide.invalid_query.returns_no_rows`. Set this property to true to return no rows on an invalid query.

**Note:** The `glide.invalid_query.returns_no_rows` property controls the behavior of all queries across the instance, such as in lists, scripts (`GlideRecord.query()`), and web service APIs.
sysparm_view

UI view for which to render the data. Determines the fields returned in the response.

Valid values:
- desktop
- mobile
- both

If you also specify the sysparm_fields parameter, it takes precedence.

Data type: String

Dot-walking in REST API requests

You can use dot-walking when specifying the sysparm_query or sysparm_fields parameters in requests to REST APIs that support those parameters.

ℹ️ Note: The Import Set API does not support dot-walking.

Dot-walking in sysparm_query

You can filter queries using related record values by dot-walking in the sysparm_query parameter. For example, you can retrieve all incident records where the incident **Company** has a specific **Stock symbol** value.

https://<instance>.service-now.com/api/now/table/incident?
sysparm_query=company.stock_symbol=NYX

Dot-walking in sysparm_fields

You can view field values from multiple tables by dot-walking in the sysparm_fields parameter. For example, you can retrieve the **Name**, **Sys_id**, and **Department** of each user that has certain roles, as well as the role **Name**.

The request runs on the User Roles [sys_user_has_role] table which defines a many-to-many relationship between users and roles. The response includes field values from the User [sys_user] and Roles [sys_user_role] tables.

https://<instance>.service-now.com/api/now/table/sys_user_has_role?
sysparm_fields=role%2Crole%2Crole.name%2Cuser%2Cuser.name%2Cuser.sys_id%2Cuser.department%2Csysparm_query=role%3D3d3d43716d0f6002003a2d47bce1050e0d%5EORrole%3Dac73b52d0f6002003a2d47bce1050e0e&sysparm_display_value=true
REST API HTTP response codes

Calls made to REST endpoints return HTTP response codes. You can use these response codes to ensure that the REST API executed properly. If it did not, the endpoint returns an error response code. Use the information in the error response to troubleshoot issues with your call format. For a list of standard response codes that an endpoint may return, see REST API HTTP response codes. For the list of response codes returned by a specific ServiceNow REST API, see the REST API reference.

REST API security

By default, ServiceNow REST APIs use basic authentication or OAuth to authorize user access to REST APIs/endpoints. You can also configure your instance to use multi-factor authentication to access REST APIs. There is no support for inbound mutual authentication.

The user ID that you specify in a REST endpoint call is subject to access control in the same way as an interactive user. Each request requires the proper authentication information, such as user name and password. Ensure that each endpoint request includes an Authorization header with sufficient credentials to access the endpoint.

ServiceNow REST APIs also support cookies that enable binding to the existing session.

REST API roles

In addition to user authentication, each REST endpoint can have different requirements for the roles required to access the endpoint. Some require the admin role and others require API specific roles. Role requirements are specified in the access control list (ACL) associated with the REST API/endpoint. For specifics on the valid roles for each REST API/endpoint, refer to the REST API reference or locate the associated ACL for the API/endpoint within an instance through Security System > Access Control (ACL).
REST API ACLs

REST API ACLs define criteria, such as the roles needed and conditions that a user must meet to access a ServiceNow REST API or endpoint. A single ACL may be defined for an entire REST API, such as the Table API and Attachment API ACLs, or for an individual endpoint, such as the clotho_rest_put ACL that only applies to MetricBase PUT methods.

The following ServiceNow REST API ACLs are available in the base system but are deactivated by default. All other ServiceNow REST API ACLs are active by default.

- Table API
- Aggregate API
- Import Set API
- Attachment API

For additional information on ACLs, see Access control list rules.

**Important:** You should never modify the names of REST API ACLs.

REST API table access

By default, all tables, including base system tables, global tables, and scoped tables are accessible through web services. You must fulfill any web service security requirements, such as basic authentication and ACLs to access tables through web services.

To allow access to tables without any authentication or authorization, add the table name to the Public Pages [sys_public] table with a status of Active. The REST interface still enforces any defined ACLs on associated tables. If ACL enforcement is not the desired behavior, you must deactivate the ACLs on the tables, which is not typically suggested.

You can also control direct web service access to tables using the Allow access to this table via web services check box on the table application access settings. You must select this check box to enable web service interaction with the table.

**Note:** The application access fields controlling CRUD operations, such as Can read or Can create do not apply to web service requests.

Multi-factor authentication for inbound REST

When multi-factor authentication is enabled for a user account, you must submit an MFA token with basic auth credentials when making REST requests as that user.
To send an MFA token with a REST request, append the token to the end of the user’s password in the basic auth username:password string, such as `joe.employee:password62161147`. Encode the full string including the MFA token using base64 encoding, then send the encoded string in the Authorization header.

**Multi-factor authentication REST responses**

The response to an MFA authentication request varies depending on the validity of the provided credentials and MFA token.

<table>
<thead>
<tr>
<th>Result</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic auth credentials and MFA token are valid</td>
<td>User is authenticated and the session created. The request is processed normally.</td>
</tr>
<tr>
<td>Basic auth credentials are valid but MFA token is invalid or missing</td>
<td>Response returns error 401. The response includes the X-MFA_TOKEN header with the value <code>invalid</code>.</td>
</tr>
<tr>
<td>Basic auth credentials are invalid</td>
<td>Response returns error 401. The X-MFA_TOKEN header is not included in the response.</td>
</tr>
</tbody>
</table>

**REST API CORS support**

The REST API supports cross-origin resource sharing (CORS) security. CORS support allows you to define which domains can access each REST API. By defining a CORS rule for a domain, you can allow cross-origin requests from that domain. Cross-origin requests cannot be made from domains without a CORS rule.

⚠️ **Note:** CORS support applies only to REST APIs, including scripted REST web services. Other web service APIs, such as the SOAP API, do not support CORS.

You can configure CORS to allow access to only certain APIs/endpoints, HTTP methods, and headers from other domains. For example, you can limit requests to the Table API from a specific domain to allow only GET operations.

To view the CORS rules defined on your instance, navigate to System Web Services > CORS Rules.

You can disable CORS support for an instance by setting the `glide.rest.cors.enabled` property to `false`. When `false`, no CORS evaluation is performed on incoming REST requests. This property is `true` by default.
REST API Explorer

The REST API Explorer is a ServiceNow tool that uses information from your instance to provide a list of endpoints, methods, and variables that you can use to build and send REST requests.

After you build the request, the REST API Explorer provides code samples in multiple programming languages that you can use to initiate the request, and detailed request and response information.

To access the REST API Explorer, in your instance, navigate to System Web Services > REST API Explorer. You must have the rest_api_explorer role to access the REST API Explorer. For additional information, see Use the REST API Explorer.

⚠️ Warning: The REST API Explorer interacts with data on the current instance. Use caution when working with requests that create, edit, or delete data on a production instance.

Automated Test Framework support

The Automated Test Framework (ATF) supports inbound REST test steps. You can create automated tests for custom inbound REST APIs that you create. Creating tests for your custom REST APIs simplifies upgrade testing, and makes it possible to verify that modifications to a REST API are backward compatible.

Example REST client applications

Several example REST client applications and source code are available to demonstrate integrations using REST web services. The example REST client applications demonstrate how to use the ServiceNow REST API with an external application, such as a NodeJS or iOS application.

ℹ️ Important: These applications are provided only as a demonstration of the REST functionality and are not officially supported.

The examples are open source and available to the community. You can use these example applications to help familiarize yourself with the REST functionality, or use them as a starting point to create your own REST client applications.

Users with the rest_api_explorer role can access the list of available client applications by navigating to System Web Services > REST > Example Client Apps.

When viewing the list of applications, click an application to view the source code and additional documentation hosted on GitHub.
Developer training
On the ServiceNow® Developer Site, you can get training for Inbound REST integrations and Outbound REST integrations.

Additional information
The remainder of the REST API section contains "how to" topics that describe specific implementations using the ServiceNow REST API and provides reference information that describes various data elements used by the ServiceNow REST API.

REST API FAQ

Use the REST API Explorer
In this tutorial you will use the REST API Explorer to test the ServiceNow REST APIs.
The REST API Explorer allows you to discover ServiceNow REST APIs, quickly construct and execute requests, and view responses from ServiceNow REST APIs within your browser. Before beginning, ensure that your user account has the rest_api_explorer and web_service_admin roles. These roles are required to complete the example procedures.

Access the REST API Explorer
View available REST API resources using the REST API Explorer.

Before you begin
Role required: web_service_admin, rest_api_explorer, or admin

About this task
You can browse available APIs, API versions, and methods for each API.

Procedure
Navigate to **System Web Services > REST API Explorer.**
Retrieve existing incidents

Use a GET request to view existing incident records.

Before you begin
Role required: admin, web_service_admin, or rest_api_explorer

About this task
Use the REST API Explorer to send the following request:

GET https://instance.service-now.com/api/now/v1/table/incident

Procedure
1. In the top-left of the REST API Explorer, select Table API and version v1.
2. Click Retrieve records from a table (GET). For information, see Table API - GET table
3. In the Path Parameters section, select the Incident (incident) table.
4. Scroll to the bottom of the page and click Send.

The response includes incident records from the instance. The REST API Explorer limits queries to 10 records at a time. Only the first 10 incident records appear. The response also includes a Link header that provides the URL to query the next 10 incident records.
The response also indicates the **Status code** and **Execution time** (in milliseconds) of the request.

<table>
<thead>
<tr>
<th>Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Status code</td>
<td>200 OK</td>
</tr>
<tr>
<td>Execution time</td>
<td>85 ms</td>
</tr>
</tbody>
</table>

**Response Body**

```
{
    "result": [
        {
            "parent": "",
            "made_sla": "true",
            "closed_by": "",
            "closed_time": "",
            "upon_reject": "cancel",
            "sys_updated_on": "2013-06-02 16:48:36",
            "child_incidents": "1",
            "hold_reason": "",
            "approval_history": "",
            "skills": "",
            "number": "386018885",
            "resolved_by": "",
            "sys_updated_by": "admin",
        }
    ]
}
```

**Create an incident record**

Use a POST request to create a new record.

**Before you begin**

Role required: admin, web_service_admin, or rest_api_explorer

**About this task**

Use the REST API Explorer to send the following request:
**POST** https://instance.service-now.com/api/now/v1/table/incident

**Procedure**
1. In the top-left of the REST API Explorer, click **Create a record (POST)**.
2. In the Path Parameters section, select the **Incident (incident)** table.
3. In the Request Body section, click **Add a field**.
4. Select a field and specify a value for that field.
5. **Optional:** Click the plus sign (+) and specify any additional field to assign a value to.
   The request body updates automatically based on your entries, such as
   `{ "short_description":"Test incident creation through REST", "comments":"These are my comments" }
6. After constructing the request, click **Send**.
   The response includes a Location header that specifies where the incident was created and how to retrieve the incident.

   ☑ **Tip:** Record this header to use in the next part of this guide.
The response also indicates the **Status code** and **Execution time** (in milliseconds) of the request.

### Response

<table>
<thead>
<tr>
<th>Status code</th>
<th>201 Created</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution time (ms)</td>
<td>1298</td>
</tr>
</tbody>
</table>

### Headers

- Cache-control: no-cache, no-store, must-revalidate, max-age=1
- Content-encoding: gzip
- Content-type: application/json; charset=UTF-8
- Date: Thu, 11 Sep 2018 19:00:45 GMT
- Expires: 0
- Location: https://api.now/v1/table/incident/f08f88bac134e23c0f06c33226144b0d4
- Pragma: no-store, no-cache
- Server: ServiceNow
- Strict-transport-security: max-age=63072000; includeSubDomains
- Transfer-encoding: chunked
- X-la-logged-in: true
- X-transaction-id: 93b8887ac13a8

### Response Body

```json
{  "result": {  "parent": "",  "made_sla": "true",  "caused_by": "",  "watch_list": "",  "upon_reject": "cancel",  "sys_updated_on": "2018-09-11 19:00:45",  "child_incidents": ""0",  "held_reason": "",  "approval_history": """,  "skills": "",  "number": "INC00100009",  "resolved_by": "",  "sys_updated_by": "terry.barracoughsnc",  "opened_by": ""}}
```

## Read the inserted incident

Use the Location header from the POST response to run a GET request.

### Before you begin

**Role required:** admin, web_service_admin, or rest_api_explorer

**About this task**

Use the REST API Explorer to send the following request:

```
GET https://instance.service-now.com/api/now/v1/table/incident/{sys_id}
```
Procedure

1. In the top-left of the REST API Explorer, click **Retrieve a record (GET)**.
2. In the Path Parameters section, select the incident table.
3. In the **sys_id** field, enter the sys_id of the record you created.
   The record sys_id appears as a 32-character string at the end of the POST response Location header.
4. Click **Send**.
   The response body contains a text representation of the record. You can control the format of the response, such as JSON or XML, using the **Response Format** field.
   The response also indicates the **Status code** and **Execution time** (in milliseconds) of the request.
Update the incident

Update the incident record using either a PUT or PATCH function.

**Before you begin**
Role required: admin, web_service_admin, or rest_api_explorer

**About this task**
Use the REST API Explorer to send the following request:

PUT https://instance.service-now.com/api/now/v1/table/incident/{sys_id}?sysparm_exclude_ref_link=true

**Procedure**

1. In the top-left of the REST API Explorer, click **Modify a record (PUT)** or **Update a record (PATCH)**.
2. In the Path Parameters section, select the **Incident (incident)** table.
3. In the **sys_id** field, enter the sys_id of the record you created.
4. In the Request Body section, click **Add a field**.
5. Select the **Short description** field and specify a new value.
6. Click **Send**.
   - The response indicates the **Status code** and **Execution time** (in milliseconds) of the request.
7. Verify that the Response Body contains the updated **short_description** value.

**Delete the incident**

Delete the incident using a DELETE request.

**Before you begin**

Role required: admin, web_service_admin, or rest_api_explorer

**About this task**

Use the REST API Explorer to send the following request:

```
DELETE https://instance.service-now.com/api/now/v1/table/incident/{sys_id}
```

**Procedure**

1. In the top-left of the REST API Explorer, click **Delete a record (DELETE)**.
2. In the Path Parameters section, select the **Incident (incident)** table.
3. In the **sys_id** field, enter the **sys_id** of the record you created.

4. Click **Send**.

   The response indicates the **Status code** and **Execution time** (in milliseconds) of the request.

![Response Table](image)

**Response**

<table>
<thead>
<tr>
<th>Status code</th>
<th>204 No Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execution time (ms)</td>
<td>2699</td>
</tr>
<tr>
<td>Headers</td>
<td></td>
</tr>
<tr>
<td>Content-encoding</td>
<td>gzip</td>
</tr>
<tr>
<td>Date</td>
<td>Tue, 11 Sep 2018 21:10:59 GMT</td>
</tr>
<tr>
<td>Server</td>
<td>ServiceNow</td>
</tr>
<tr>
<td>Strict-transport-security</td>

</tr>
<tr>
<td>X-transaction-id</td>
<td>2a96ab6c1328</td>
</tr>
</tbody>
</table>

5. Verify that the response **Status code** is **204**.

**Explore the REST API for a table**

You can explore the REST API for a table directly from that table. Explore the API using the REST API Explorer to quickly construct and test REST requests for that table.

**Before you begin**

Role required: itil, personalize_dictionary, and rest_api_explorer

**Procedure**

1. Navigate to any form or list.
2. In a form, right-click the form header and select **Configure > Table**.
3. In a list, perform the appropriate action for the list version.
• For List v2, right-click any column heading and select **Configure > Table**.

• For List v3, open the list title menu and select **Configure**, and then click **Table**.

**4. Click the Explore REST API related link.**

The REST API Explorer opens, displaying the Table API for the selected table. If the table does not allow web service interaction, a warning appears instead.

**What to do next**

Use the REST API Explorer to construct and test REST requests for the table.

**Inbound REST API rate limiting**

To prevent excessive inbound REST API requests, set rules that limit the number of inbound REST API requests processed per hour. You can create rules to limit requests for specific users, users with specific roles, or all users.

⚠️ **Note:** As requests reach an instance, each node maintains a rate limit count per user. Every 30 seconds, the count is committed to the database. As a result, a rate limit rule may not take effect for up to 30 seconds.

**Rate limiting priority**

If an inbound REST API request matches multiple rate limit rules for the same resource, rate limiting priority is enforced as follows:

• Rules set for **Single user** override rules for **All users** and rules for **Users with role**.

• Rules set for **Users with role** override rules for **All users**.

In this example, there are four rate limit rules for the same REST API resource: GET /now/v2/table/incident:

<table>
<thead>
<tr>
<th>Name</th>
<th>REST API resource</th>
<th>Requests</th>
<th>Type</th>
<th>Role</th>
<th>User</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limit Incidents</td>
<td>GET /now/v2/table/incident</td>
<td>2</td>
<td>All users</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Limit Incidents by import admin Role</td>
<td>GET /now/v2/table/incident</td>
<td>3</td>
<td>Users with role</td>
<td>import admin</td>
<td></td>
</tr>
<tr>
<td>Limit Incidents by llb Role</td>
<td>GET /now/v2/table/incident</td>
<td>5</td>
<td>Users with role</td>
<td>llb</td>
<td></td>
</tr>
<tr>
<td>Limit Incidents by user</td>
<td>GET /now/v2/table/incident</td>
<td>10</td>
<td>Single user</td>
<td>IT User</td>
<td></td>
</tr>
</tbody>
</table>

These rate limit rules are applied in the following order:
1. **Limit Incidents by User** applies to ITIL User, who can submit up to 10 requests per hour.

2. **Limit Incidents by import admin Role** applies to each user with the import_admin role. Each user with the import_admin role can submit up to three requests per hour.

3. **Limit Incidents by itil Role** applies to each user with the itil role. Each user with the itil role can submit up to five requests per hour.

4. **Limit Incidents** applies to all users. Each user can submit up to two requests per hour.

When ITIL User makes the request `GET /now/v2/table/incident`, the request matches the criteria for three rules: Limit Incidents, Limit Incidents by itil Role, and Limit Incidents by User. Only the Limit Incidents by User rule is applied because it takes precedence over the other rules. As a result, ITIL User can submit a maximum of 10 requests per hour.

If a user has two or more roles matching the criteria of multiple rate limiting rules for a REST API resource, the rule allowing the lowest number of requests applies to the user's requests for the resource. For the example rules in the figure above, assume that user Abel Tuter has both the import_admin role and the itil role. When Abel Tuter submits a request, it meets the criteria for both the Limit Incidents by admin Role rule and the Limit Incidents by itil Role rule. Only the Limit Incidents by admin Role rule is applied because it allows the lowest number of requests. As a result, Abel Tuter can submit a maximum of three requests per hour.

**REST API response headers**
You can generate inbound REST API requests using the Use the REST API Explorer or an HTTP client, such as Postman. If the request matches a rate limit rule, several HTTP response headers provide information about rate limiting:

- **X-RateLimit-Limit** displays the number of requests allowed per hour.
- **X-RateLimit-Reset** displays the Unix time until the next scheduled reset.
• **X-RateLimit-Rule** displays the sys_id of the rate limit rule that is being enforced.

<table>
<thead>
<tr>
<th>Body</th>
<th>Cookies (4)</th>

</tbody>
</table>

If a request is denied because it exceeds the rate limit, the system returns a **Retry After** response header in addition to the response headers about rate limiting. The **Retry After** response header displays the number of seconds after which you can retry the request to avoid exceeding the rate limit. The following error response is returned:

```
{
    "error": {
        "message": "Rate limit exceeded",
        "detail": "Rate limit of 10 requests per hour for Table API exceeded"
    },
    "status": "failure"
}
```

The status of a denied request is **429 Too Many Requests**.
Create an inbound REST API rate limit

Create rate limit rules to limit the number of inbound REST API requests processed per hour.

Before you begin
Role required: rate_limit_admin

About this task
Set rate limits for all users, users with specific roles, or all users.

Note: As requests reach an instance, each node maintains a rate limit count per user. Every 30 seconds, the count is committed to the database. As a result, a rate limit rule may not take effect for up to 30 seconds.

Procedure
1. Navigate to System Web Services > REST > Rate Limit Rules.
2. Click New and enter the following field values.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REST API resource</td>
<td>Value derived from the values entered at the following fields.</td>
</tr>
<tr>
<td>Name</td>
<td>Unique name for the rate limit rule.</td>
</tr>
<tr>
<td>REST API</td>
<td>REST API selected from the list of all external-facing REST APIs for the instance.</td>
</tr>
<tr>
<td>Version</td>
<td>Version of the REST API. Values listed depend on the REST API selected.</td>
</tr>
<tr>
<td><strong>Field</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Resource</td>
<td>Resource for the <strong>Version</strong>. Values listed depend on the <strong>Version</strong> selected.</td>
</tr>
<tr>
<td>Table</td>
<td>Table that you want to target. Appears only when you select <strong>Table API</strong> as the <strong>REST API</strong>.</td>
</tr>
<tr>
<td>Import set table</td>
<td>Import set table that you want to target. Appears only you select <strong>Import Set API</strong> as the <strong>REST API</strong>.</td>
</tr>
<tr>
<td>Active</td>
<td>Check box to indicate that the rate limit rule is active. Rate limit rules are activated by default as soon as you create them. You can deactivate rate limit rules to stop enforcing a rate limit or activate rate limit rules to resume enforcing a rate limit.</td>
</tr>
<tr>
<td>Request limit per hour</td>
<td>Maximum number of requests allowed per hour.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Whenever you update the value of this field, the Now Platform resets the count of requests to 0 and deletes all violations for the current hour.</td>
</tr>
<tr>
<td>Apply to</td>
<td>Users restricted by this rule:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Single user</strong> applies the rate limit to a specific user.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Users with role</strong> applies the rate limit to all users with a specific role.</td>
</tr>
<tr>
<td></td>
<td>• <strong>All users</strong> applies the rate limit to all users.</td>
</tr>
<tr>
<td>Role</td>
<td>Role to which the rate limit applies. Appears only when you select <strong>Users with role</strong> at the <strong>Apply to</strong> field.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>User</td>
<td>User to whom the rate limit applies. Appears only when you select <strong>Single user</strong> at the <strong>Apply to</strong> field.</td>
</tr>
</tbody>
</table>

3. Click **Submit**. The new rate limit goes into effect.

**What to do next**
After you submit the rule, the Now Platform adds the following related lists to the rule record:

- **Rate Limit Counts**
  Lists, by user, the number of inbound REST API requests affected by this rate limit rule.

- **Rate Limit Violations**
  Lists, by user, the violations of this rate limit rule.

You can use these related lists to **Monitor inbound REST API rate limit counts and violations**.

**Reset an inbound REST API rate limit**
Reset a rate limit rule to reset the rate limit count to zero (0) and delete any violations for the current hour.

**Before you begin**
Role required: rate_limit_admin

**Procedure**
1. Navigate to **System Web Services > REST > Rate Limit Rules**.
2. Select the rate limit rule for which you want to reset the rate limit count.
3. Click the **Reset Rate Limit Counts** related link.

**Results**
For the current hour, the system resets the rate limit count for the rate limit rule to zero (0) and removes all violations. The system begins incrementing the rate limit counts and violations as REST API requests are received for processing.

**Monitor inbound REST API rate limit counts and violations**
To determine if you have set a rate limit rule appropriately, monitor the counts and violations for inbound REST API requests that are restricted by the rule.
Before you begin
Role required: rate_limit_admin

Procedure
1. Navigate to System Web Services > REST > Rate Limits.
2. Select the rate limit rule for which you want to monitor rate limit counts and violations.
3. View the information in the following related lists:
   • In the Rate Limit Counts related list, view the count of inbound REST API requests limited by the rule. This list is cleared daily.
   • In the Rate Limit Violations related list, view the number of inbound REST API requests that exceeded the Request limit per hour value for the rule. This list is cleared biweekly.

Investigate inbound REST API rate limit violations
Investigate rate limit violations to determine which rate limit rules are being exceeded and which users are exceeding those rate limits.

Before you begin
Role required: rate_limit_admin

About this task
Violations are created when inbound REST API requests reach the maximum allowed request count for a specific REST API for that hour.

Procedure
1. Navigate to System Web Services > REST > Rate Limit Violations.
2. On the Rate Limit Violations page, select the rate limit rule that you want to investigate.
3. On the Rate Limit Violations related list, review the violations by user. This list is cleared biweekly.

What to do next
You may need to reevaluate the Request limit per hour value for a rate limit rule, depending on the number of violations of that rule. You may also need to educate users about rate limits, depending on how many times specific users violate rate limit rules.
Debug REST queries

You can debug REST queries by reviewing the session debug log.

When the `glide.rest.debug` property is `true`, all REST processing is logged in the session debug log.

REST Logging includes processing durations, headers, and the request body. Prolonged use of this property can affect performance, so it is best to use it while debugging REST processing, and then set the property back to `false`.

⚠️ **Note:** You may not see the resulting log statements if you are not on the application node that processed your REST request. In this case, please contact Technical Support.

You can include session debug logs in a REST response body by passing the `X-WantSessionDebugMessages` header in the request. For more information, see Returning session debug logs in a REST response. To view debug logs, see Display debugging logs.

Sample log output

```
#28 /api/now/table/incident

Return session debug logs in a REST response

You can include session debug logs in a REST response body by passing the X-WantSessionDebugMessages header in the request.

To return session debug messages when session debugging is enabled for the current session, set the header X-WantSessionDebugMessages to true in the REST request.

⚠️ Note: You must enable session debugging before sending this header.

**Example: Request**

This example demonstrates a Table API request made using REST API Explorer with Session Debug SQL enabled.

```
GET api/now/table/incident/9c573169c611228700193229fff72400
X-WantSessionDebugMessages:true
Content-Type: application/json; charset=UTF-8
Accept: application/json, text/plain,*/*
X-UserToken: <user token>
```
Example: Response body

```json
{
    "result": {
        "description": "User can't access email on mail.company.com.",
        "number": "INC0000001"
    },
    "session": {
        "debug_logs": [
            {
                "type": "sql",
                "customerUpdate": false,
                "line": "17:17:27.777: Time: 0:00:00.000 for: glide_master_db[glide.5] .... sys_user_session0.id = '3BEA7001EB230200C46AC2EEF106FE2A'",
                "debugClassSet": ""
            },
            {
                "type": "sql",
                "customerUpdate": false,
                "line": "17:17:27.779: Time: 0:00:00.002 for: glide_master_db[glide.6] .... \`sys_id` = '7f97b01ebc230200c46ac2eeff106f2a'",
                "debugClassSet": ""
            }
        ]
    }
}
```

**CORS domain requirements**

When you define a cross-origin resource sharing (CORS) rule, the value you enter in the **Domain** field must meet certain requirements. Each CORS rule supports a single wildcard to match incoming Origin headers.

**Requirements**

The value you enter in the **Domain** field must meet the following requirements.

- Begins with **HTTP://** or **HTTPS://**.
- Is a domain pattern or IP address.
- Ends with alphanumeric characters preceded by a period, such as .com.
- Includes at most a single wildcard character immediately following the scheme and hierarchical portion of the domain pattern.

### Wildcard

You can use a single wildcard character (*) in the domain pattern. Use this wildcard immediately following the scheme and hierarchical portion of the domain pattern, such as http://*.domain.com to include all subdomains. The wildcard must immediately follow the scheme and hierarchical portion of the domain pattern. If you use an IP address instead of domain pattern, you must enter the full IP address without a wildcard.

**Note:** You cannot use multiple wildcards, or specify a wildcard without a domain pattern. Values such as * or *.* are not supported.

### Domain matching

When evaluating the Origin header in a request, ServiceNow prioritizes rules that match the domain pattern exactly. If no exact match is found, the next closest match is used.

For example, if there are rules for the domain patterns `http://*.blog.mysite.com` and `http://*.mysite.com`, a request from `http://alice.blog.mysite.com` will match the `http://*.blog.mysite.com` pattern.

### Examples of valid and invalid domains

<table>
<thead>
<tr>
<th>Valid domain</th>
<th>Invalid domain</th>
</tr>
</thead>
<tbody>
<tr>
<td>http://*.ms.net</td>
<td>https://*com</td>
</tr>
<tr>
<td>https://*.ms.com</td>
<td>http://*.com</td>
</tr>
<tr>
<td><a href="http://192.168.1.1">http://192.168.1.1</a></td>
<td>http://*.168.1.126</td>
</tr>
<tr>
<td>http://*.service-now.com</td>
<td><a href="http://blog.*.service-now.com">http://blog.*.service-now.com</a></td>
</tr>
<tr>
<td>http://*.com</td>
<td>http://*com</td>
</tr>
</tbody>
</table>
**Define a CORS rule**

You can define a CORS rule to control which domains can access specific REST API endpoints.

**Before you begin**

Role required: web_service_admin

**Procedure**

1. Navigate to **System Web Services > CORS Rules**.
2. Click **New**.
3. Populate the form.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REST API</td>
<td>Select the REST API this CORS rule applies to, such as the Table API.</td>
</tr>
<tr>
<td>Domain</td>
<td>Enter the domain that this CORS rule applies to. This CORS rule is evaluated against requests from the specified domain. You can specify a domain pattern or an IP address. When using a domain pattern you can specify a single wildcard to match incoming origin headers.</td>
</tr>
<tr>
<td>HTTP Methods</td>
<td>Select the HTTP methods allowed. Only the selected methods can be called from the specified domain.</td>
</tr>
<tr>
<td>HTTP Headers</td>
<td>Enter a comma-separated list of HTTP headers to send in the response. Specified headers are added to the Access-Control-Expose-Headers header.</td>
</tr>
<tr>
<td>Max Age</td>
<td>Enter the number of seconds to cache the client session. After an initial CORS request, further requests from the same client within the specified time do not require a preflight message. If you do not specify a value, the default value of 0 indicates that all requests require a preflight message.</td>
</tr>
</tbody>
</table>

4. Click **Submit**.

**Enable OAuth with inbound REST**

Using OAuth, you can pass a user ID and password once, and then use a token for subsequent REST requests instead of submitting credentials with each request.
About this task
OAuth can improve system security by reducing the number of times you submit user credentials. You can use OAuth to authenticate REST requests.
This video demonstrates how to authenticate to REST APIs using OAuth.
How to authenticate to REST APIs using OAuth

Procedure
1. Activate the OAuth 2.0 plugin.
2. Set the system property com.snc.platform.security.oauth.is.active to true.
3. Navigate to System OAuth > Application Registry.
4. Click New and then click Create an OAuth API endpoint for external clients.
5. Record the client_id and client_secret values from the previous step to use when requesting an access token.
6. To get an access token, use your REST client, such as cURL or Postman, to send a request to the OAuth endpoint (oauth_token.do).
   Format the request as a URL-encoded HTTP POST body and include the required parameters.
7. Record the access token and refresh token from the response.
8. Submit the access token with subsequent REST requests.

REST OAuth example
This example shows how to authenticate an inbound REST request using OAuth.
In this example, the OAuth token has a client_id of a329c4515612210071a5e0c298ee2be8 and a client_secret of password22.

Getting an access token

```sh
curl -d "grant_type=password&client_id=a329c4515612210071a5e0c298ee2be8&client_secret=password22&username=RESTUser&password=RESTUserPassword" https://<instance>.service-now.com/oauth_token.do
```

Sample token response

```
{
  "scope": "useraccount",
  "token_type": "Bearer",
  "expires_in": 1799,
}
```
REST request with OAuth token

```
2wRlsRCT2SYjCCJP91kwo2EFzj5qg40I33aC09e0-0h6Ib33YK7If-LMiNorNuglfqbkL4AfkYC92KYHUCcbpQ"
"https://<instance>.service-now.com/api/now/table/incident
```

REST API HTTP response codes

REST Messages sent to an instance return a specific HTTP response code.

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Message</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Success</td>
<td>Success with response body.</td>
</tr>
<tr>
<td>201</td>
<td>Created</td>
<td>Success with response body.</td>
</tr>
<tr>
<td>204</td>
<td>Success</td>
<td>Success with no response body.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request</td>
<td>The request URI does not match the APIs in the system, or the operation failed for unknown reasons. Invalid headers can also cause this error.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized</td>
<td>The user is not authorized to use the API.</td>
</tr>
<tr>
<td>403</td>
<td>Forbidden</td>
<td>The requested operation is not permitted for the user. This error can also be caused by ACL failures, or business rule or data policy constraints.</td>
</tr>
<tr>
<td>404</td>
<td>Not found</td>
<td>The requested resource was not found. This can be caused by an ACL constraint or if the resource does not exist.</td>
</tr>
<tr>
<td>405</td>
<td>Method not allowed</td>
<td>The HTTP action is not allowed for the requested REST API, or it is not supported by any API.</td>
</tr>
<tr>
<td>406</td>
<td>Not acceptable</td>
<td>The endpoint does not support the response format specified in the request Accept header.</td>
</tr>
<tr>
<td>415</td>
<td>Unsupported media type</td>
<td>The endpoint does not support the format of the request body.</td>
</tr>
</tbody>
</table>
REST API reference
You can use REST interfaces to access data on your instance.

Account API
The Account REST API enables you to retrieve and update Customer Service Management (CSM) account records.

In addition, you can generate new social media profile records when creating an account.

The Account API requires the Customer Service plugin (com.sn_customerservice) and is provided within the now namespace.

Users require the csm_ws_integration role for full API access.

Account - GET /now/account
Retrieves a specified set of Customer Service Management (CSM) accounts.

URL format
Versioned URL: /api/now/{api_version}/account
Default URL: /api/now/account

Supported request parameters

<table>
<thead>
<tr>
<th>Path parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>api_version</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Query parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>sysparm_limit</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, <code>sysparm_offset</code> is set to &quot;0&quot;. To simply page through all available records, use <code>sysparm_offset=sysparm_offset+sysparm_limit</code>, until you reach the end of all records. Do not pass a negative number in the <code>sysparm_offset</code> parameter. Data type: Number Default: 0</td>
</tr>
</tbody>
</table>
| sysparm_query    | Encoded query used to filter the result set. For example:  

```plaintext
sysparm_query=caller_id=javascript:gs.getUserID()\^active=true
```

The encoded query supports order by. To sort responses based on certain fields, use the ORDERBY and ORDERBYDESC clauses in `sysparm_query`. For example, `sysparm_query=active=true\^ORDERBYnumber\^ORDERBYDESCcategory` filters all active records and orders the results in ascending order by number first, and then in descending order by category.

If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the property `glide.invalid_query.returns_no_rows`. Set this property to true to return no rows on an invalid query.

**Note:** The `glide.invalid_query.returns_no_rows` property controls the behavior of all queries across the instance, such as in lists, scripts (`GlideRecord.query()`), and web service APIs.

exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
Account - GET /now/account/{id}
Retrieves the specified Customer Service Management (CSM) account.

**URL format**

Versioned URL: /api/now/{api_version}/account/{id}
Default URL: /api/now/account/{id}

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>id</td>
<td>Sys_id of the account to retrieve. Located in the Customer [customer_account] table. Data type: String</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>

<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>404</td>
<td>Indicates that the request is invalid. Could be due to one of the following reasons:</td>
</tr>
</tbody>
</table>
Status codes (continued)

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>•</td>
<td>Requested case does not exist.</td>
</tr>
<tr>
<td>•</td>
<td>User does not have access to the account record.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>

Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/account/59e788fbd1b1200b6075200cf9619d2'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept': 'application/xml'}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```

```xml
<response>
  <result>
    <country>USA</country>
    <notes/><gender>Female</gender>
    <city>Santa Clara</city>
  </result>
</response>
```
ActivitySubscriptions API
Use the ActivitySubscriptions API to retrieve Activity entities from the Subscriptions and Activity Feed Framework.

This API requires activation of the Subscriptions and Activity Feed Framework (com.snc.activity_subscriptions) plugin. Activate the Customer Central
(com.sn_csm_customer_central) plugin to seed configuration in all required tables. For more information on customer central configuration settings, see Configure customer central.

**ActivitySubscriptions - GET /now/actsub/activities**

Retrieves activity records from the Subscriptions and Activity Feed Framework.

No role is required to access this endpoint, but data returned is limited by user access settings.

**URL format**

Versioned URL: /api/now/{api_version}/actsub/activities

Default URL: /api/now/actsub/activities

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>api_version</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Query parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>before</td>
</tr>
<tr>
<td>context_instance</td>
</tr>
</tbody>
</table>
## Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>to retrieve. Located in the appropriate table for the activity context.</td>
</tr>
<tr>
<td></td>
<td>As an example, if you set <code>context</code> to the sys_id of the Consumer activity context, set this parameter to the sys_id of the Consumer <code>[csm_consumer]</code> table record for the consumer whose activities you want to retrieve.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>end_date</td>
<td>Date/time value. The request returns only records created during the time period defined by <code>start_date</code> and this parameter. Must be set along with <code>start_date</code>.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Format: <code>YYYY-MM-DD hh:mm:ss</code> or <code>YYYY-MM-DD</code></td>
</tr>
<tr>
<td>facets</td>
<td>Comma-separated list of sys_ids of activity facet types to retrieve for the specified activity context. These sys_ids are located in the Activity Facet <code>[sn_actsub_facet]</code> table.</td>
</tr>
<tr>
<td></td>
<td>For more details on activity facets, see Create facets for activity contexts.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Default: Return all activity facet types configured for the activity context.</td>
</tr>
<tr>
<td>last</td>
<td>Index value of the first result row omitted from the response body. The result row index starts at 0, so the last row included in the response body is the one with the index <code>last-1</code>.</td>
</tr>
<tr>
<td></td>
<td>For example, setting <code>last=5</code> omits rows with index 5 and above and returns at most only the first five result rows (with index values 0 through 4). Setting <code>stFrom=1</code> and <code>last=5</code> skips the first result row and returns the second through fifth result rows (with index values 1 through 4).</td>
</tr>
<tr>
<td></td>
<td>Data type: Number (integer)</td>
</tr>
<tr>
<td></td>
<td>Default: The value of the <code>com.snc.actsub.activities.api.fetch.limit</code> system property (10 by default).</td>
</tr>
</tbody>
</table>
## Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>record_id</td>
<td>Sys_id of a record to use when rendering dynamic facets. Located in the appropriate table for the activity type you want to retrieve. For example, if you want to fetch activities for a Case record, set this parameter to the sys_id of the Case record in question. For more details on dynamic facets, see <a href="#">Create facets for activity contexts</a>. Data type: String</td>
</tr>
<tr>
<td>start_date</td>
<td>Date/time value. The request returns only records created during the time period defined by this parameter and end_date. Must be set along with end_date. Data type: String</td>
</tr>
<tr>
<td>stFrom</td>
<td>Index value of the first result row to include in the response body. The result row index starts at 0. For example, stFrom=2 skips the first two result rows and returns results from the third row onward. Data type: Number (integer) Default: 0</td>
</tr>
</tbody>
</table>
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected. The response body <code>result.message</code> parameter describes the nature of the error. Example error messages:</td>
</tr>
</tbody>
</table>

- Make sure a valid context and context_instance are passed or Make sure a valid stream and user are passed indicates that the request lacks one or both of the `context` and `context_instance` query parameters. These parameters are required. 
- `stFrom` can not be greater than `last` indicates that the `stFrom` query parameter value exceeds the `last` query parameter value. 
- Please provide `start_date` and `end_date` indicates that the request includes only one of the `start_date` and `end_date` query parameters, which cannot be used separately. 
- `start_date` can not be ahead of `end_date` indicates that the specified `start_date` query parameter value occurs after the specified `end_date` query parameter value. |
Status codes (continued)

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>result.user</td>
<td>Sys_id specified in request context_instance query parameter. Located in the appropriate table for the activity context. Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

Request the second and third activity records for a specific Contact, limiting to data from 2020:

```bash
curl "https://instance.servicenow.com/api/now/actsub/activities?context=4a6a035a73d30010e37d71ef64f6a714&context_instance=ddce70866f933103b3c498f5d3ee417&stFrom=1&last=3&start_date=2020-01-01%2000:00:00&end_date=2020-12-31%2023:59:59" --request GET --header "Accept: application/json" --user "username:password"
```

The response body includes the two requested activity records for the specified Contact:

```
{
  "result": {
    "hasMoreRecords": true,
    "activities": [
      {
        "subobject_table_name": "sn_customerservice_case",
        "source_table_name": "sn_customerservice_case",
        "content_fields": [
          {
            "value": "Test",
            "show_label": "false",
            "type": "string",
            "label": "Short description",
            "display_as_timeago": "false",
            "deeplink_to_subobject": "false"
          }
        ]
      }
    ]
  }
}
```
Example: Python request

Request activity records from 2020 for a specific Contact, showing only records from the Contracts and Entitlements facets for the Contact activity context:
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/actsub/activities'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the query parameters
params = {
    'context_instance': 'ddce70866f9331003b3c498f5d3ee417',
    'context': '4a6a035a73d30010e37d71ef64f6a714',
    'facets': '0a63b6e673570010e37d71ef64f6a72b, d9d4fa2a73570010e37d71ef64f6a70a',
    'start_date': '2020-01-01 00:00:00',
    'end_date': '2020-12-31 23:59:59'
}

# Set the proper headers
headers = {'Accept': 'application/xml'}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers, params=params)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

The response body includes all 2020 Contracts and Entitlements activity records associated with the specified Contact:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <activities>
      <subobject_sys_id>451a446073181010e37d71ef64f6a703</subobject_sys_id>
      <sys_id>451a446073181010e37d71ef64f6a703</sys_id>
      <activity_type_id>fd2ff6d273d30010e37d71ef64f6a7be</activity_type_id>
    </activities>
  </result>
</response>
```

ActivitySubscriptions - GET /now/actsub/facets/{activity_context}/
{context_instance}

Retrieves facets configured for an activity context from the Subscriptions and Activity Feed Framework. Displays activity counts and data for each facet as determined by activity type, group, and context settings.

Users must have the actsub_user or admin role to access this endpoint. Data returned is limited by user access settings.

For more details on activity context facets, see Create facets for activity contexts.
URL format

Versioned URL: /api/now/{api_version}/actsub/facets/{activity_context}/
{context_instance}

Default URL: /api/now/actsub/facets/{activity_context}/
{context_instance}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>activity_context</td>
<td>Sys_id of an activity context. Located in the Activity Contexts [sn_actsub_activity_context] table. Predefined activity contexts include Consumer and Contact. Navigate to Customer Central &gt; Customer Activity &gt; Activity Contexts to view the full list of activity contexts defined for your instance. Data type: String</td>
</tr>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>context_instance</td>
<td>Sys_id of an instance of the specified activity context, representing the initiator of the activities you want to retrieve facets for. Located in the context table specified for the activity context record in the Activity Contexts [sn_actsub_activity_context] table. As an example, if you set activity_context to the sys_id of the Contact activity context, you should set this parameter to the sys_id of the Contact [customer_contact] record for the contact whose activity facets you want to retrieve. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>end_date</td>
<td>Date/time value. The request returns only records created during the time period defined by start_date and this parameter. Must be set along with start_date.</td>
</tr>
</tbody>
</table>
**Query parameters (continued)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Data type: String</td>
</tr>
<tr>
<td>Name</td>
<td>Format: YYYY-MM-DD hh:mm:ss or YYYY-MM-DD</td>
</tr>
<tr>
<td>facets</td>
<td>Comma-separated list of sys_ids of activity facets to retrieve for the specified activity context. To see the activity facet types defined for an activity context, navigate to Customer Central &gt; Customer Activity &gt; Activity Contexts and examine the Facets related list. Data type: String Default: Return all activity facets configured for the activity context.</td>
</tr>
</tbody>
</table>
| get_activity_count | Flag indicating whether or not to include activity counts for each facet in the response body. Valid values:  
• true: Include facet activity counts.  
• false: Omit facet activity counts.  
Data type: Boolean Default: false                                                                                                                                                                                                                                               |
| lazy_load      | Flag indicating whether or not to improve performance by omitting facet activity data and activity counts from the response body. This parameter takes precedence over get_activity_count. Valid values:  
• true: Omit facet activity data and activity counts.  
• false: Retrieve facet activity data and activity counts.  
Data type: Boolean Default: false                                                                                                                                                                                                                                               |
| start_date     | Date/time value. The request returns only records created during the time period defined by this parameter and end_date. Must be set along with end_date. Data type: String Format: YYYY-MM-DD hh:mm:ss or YYYY-MM-DD                                                                 |
### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

#### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

#### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected. The response body <code>result.message</code> parameter describes the nature of the error. Example error messages:</td>
</tr>
</tbody>
</table>
## Status codes (continued)

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Make sure a valid activity context details are passed indicates that the <code>activity_context</code> path parameter value does not represent a valid activity context, the <code>context_instance</code> path parameter value does not represent a valid instance of the specified activity context, or both.</td>
<td></td>
</tr>
<tr>
<td>• Please provide <code>start_date</code> and <code>end_date</code> indicates that the request includes only one of the <code>start_date</code> and <code>end_date</code> query parameters, which cannot be used separately.</td>
<td></td>
</tr>
<tr>
<td>• <code>start_date</code> can not be ahead of <code>end_date</code> indicates that the specified <code>start_date</code> query parameter value occurs after the specified <code>end_date</code> query parameter value.</td>
<td></td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| result | Array of objects in which each object represents an activity facet.  
Data type: Array |

```
"result": [ 
  { 
    "activity_count": Number, 
    "children": [Array], 
    "facets": [Array], 
    "icon": "String", 
    "is_dynamic": "String",

<td>&quot;bc9bfaaa73570010e37d71ef64f6a771&quot; ]</td>
</tr>
<tr>
<td>result.icon</td>
<td>Name of the icon associated with this facet.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>result.is_dynamic</td>
<td>Flag indicating whether or not this facet is a dynamic facet. This value determines the type of information included in the children response body parameter. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: This is a dynamic facet. The children response body parameter value contains activity record details, and the facets parameter contains the dynamic facet sys_id.</td>
</tr>
<tr>
<td></td>
<td>• false: This is a static facet (a facet group). The children response body parameter value contains child facets, and the facets parameter contains the sys_ids of these child facets.</td>
</tr>
<tr>
<td>Data type: Boolean</td>
<td></td>
</tr>
<tr>
<td>result.message</td>
<td>Error message describing problem encountered during request processing.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>result.name</td>
<td>Name of the facet or facet group.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>result.status</td>
<td>HTTP status code returned for request.</td>
</tr>
<tr>
<td>Valid values:</td>
<td>See Status Code table.</td>
</tr>
</tbody>
</table>
Example: cURL request

Retrieve Chat, Phone, and Knowledge articles facets and activity counts for a Contact:

curl
  "https://instance.servicenow.com/api/now/actsub/facets/4a6a035a73d30010e37d71ef64f6a714/ddce70866f9331003b3c498f5d33ee417?get_activity_count=true&facets=510d7e2e73570010e37d71ef64f6a70d,bc9bfaaa73570010e37d71ef64f6a771,c72d7e2e73570010e37d71ef64f6a7b8" \
  --request GET \
  --header "Accept: application/json" \
  --user "username:password"

The response body includes the three requested facets as children of their facet groups, with activity counts displayed:

```json
{
  "result": [
    {
      "is_dynamic": false,
      "name": "Interactions",
      "activity_count": 4.0,
      "facets": [
        "510d7e2e73570010e37d71ef64f6a70d",
        "bc9bfaaa73570010e37d71ef64f6a771"
      ],
      "children": [
        {
          "facet": "510d7e2e73570010e37d71ef64f6a70d",
          "icon": "chat_outline",
          "activity_count": 2.0,
          "title": "Chat"
        },
        {
          "facet": "bc9bfaaa73570010e37d71ef64f6a771",
          "icon": "phone_outline",
          "activity_count": 2.0,
          "title": "Phone"
        }
      ]
    }
  ]
}
```
Example: Python request

Retrieve facets and activity counts for activity records associated with a Contact and created in 2020:

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/actsub/facets/4a6a035a73d30010e37d71ef64f6a714/dec70866f9331003b3c498f5d3e417'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the query parameters
params = {
    'start_date': '2020-01-01 00:00:00',
    'end_date': '2020-12-31 23:59:59',
    'get_activity_count': 'true'
}

# Set the proper headers
```
headers = { 'Accept':'application/xml' }

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers, params=params)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status: ', response.status_code, 'Headers: ', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

The response body includes activity facets and facet groups for the specified Contact, with activity counts displayed for each facet and facet group:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>

Agent Client Collector API

The Agent Client Collector enables managing actions on available agents and managing policies.

This API requires the Agent Client Collector Framework (sn_agent) store application and is provided within the sn_agent namespace. The endpoints in this API require the agent_client_collector_admin role. For more information, refer to Agent Client Collector.

Agent management endpoints
• Get extensive information of one or more agents. These endpoints are also accessible to users with the agent_client_collector_user role.
  ◦ GET /agents/{agent_id}
  ◦ GET /agents/list

• Submit a request to grab an agent log and retrieving information about the request progress.
  ◦ GET /agents/{agent_id}/log
  ◦ GET /agents/log/{request_id}/

• Disable or enable agent data collection.
  ◦ GET /agents/{agent_id}/data/off
  ◦ GET /agents/{agent_id}/data/on

• Restart an agent with GET /agents/{agent_id}/restart.

• Run discovery on an agent with GET /agents/{agent_id}/discovery.

For information on performing similar tasks in a script include, see AccAgentsAPI.

Policy management and workflow

Use policy management APIs to view details, activate/deactivate a policy, update a policy, and publish a policy.

To update a policy:

1. Get a list of policies and details with GET /agents/policies/list. This endpoint requires the agent_client_collector_user role.
   • To update a policy in the Draft state, use the sys_ids retrieved from the policies list in the update endpoints.
   • To update a policy in Published or Published* state, get an editable sandbox copy with GET /agents/policy/sandbox_from_published/{policy_id}. Use the sys_ids from this response to modify properties using an update endpoint.

   • POST /agents/update/policy/{policy_id}
   • POST /agents/update/check/{check_id}
• POST /agents/update/check_param/{param_id}
• POST /agents/update/check_secure_param/{param_id}

3. Publish the policy using GET /agents/policy/publish/{policy_id}.

Once published, the policy becomes Active. This API also includes endpoints for activating or deactivating a published policy:
• GET /agents/policy/activate/{policy_id}
• GET /agents/policy/deactivate/{policy_id}

Agent Client Collector - GET /agents/{agent_id}
Gets the information of a specified agent.

**URL format**
/api/sn_agent/agents/{agent_id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent_id</td>
<td>Unique ID of an agent listed in the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table. For a list of agent IDs and other details, run the GET /agents/list endpoint. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Request body parameters (JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>403</td>
<td>The user does not have the agent_client_collector_user role.</td>
</tr>
<tr>
<td>404</td>
<td>Agent with provided ID not found.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Array&gt;</td>
<td>Array of JSON objects containing extended agent information.</td>
</tr>
</tbody>
</table>

```json
{
  "agent_id": "String",
  "data_collection": Number,
  "ip_address": "String",
  "is_duplicate": Boolean,
  "is_restart_enabled": Boolean,
}
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td><code>&quot;name&quot;: &quot;String&quot;,</code></td>
</tr>
<tr>
<td></td>
<td><code>&quot;number_of_running_checks&quot;: Number,</code></td>
</tr>
<tr>
<td></td>
<td><code>&quot;status&quot;: Number,</code></td>
</tr>
<tr>
<td></td>
<td><code>&quot;up_since&quot;: &quot;String&quot;,</code></td>
</tr>
<tr>
<td></td>
<td><code>&quot;version&quot;: &quot;String&quot;</code></td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>agent_id</td>
<td>ID of the agent as submitted.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>data_collection</td>
<td>Data collection indicates whether scheduled checks are to be run. These checks are a part of the policies scheduled for this agent to run. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• 0: On – Checks run as scheduled.</td>
</tr>
<tr>
<td></td>
<td>• 1: Off (manual) – Checks have been disabled manually.</td>
</tr>
<tr>
<td></td>
<td>• 2: Off (auto) – Checks have been disabled automatically due to high CPU consumption by the</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>ip_address</td>
<td>Agent IP address.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>is_duplicate</td>
<td>Flag that indicates whether this agent is a duplicate of another. There should be only a single agent on a given host.</td>
</tr>
<tr>
<td></td>
<td>Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: The agent has the same host as an Alive/Up agent with a different agent ID. Turn off or uninstall the duplicate</td>
</tr>
<tr>
<td></td>
<td>• false: This agent has no duplicates in the Alive/Up state.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>is_restart_enabled</td>
<td>Flag that indicates whether restart is enabled. Agent restart is not configurable. It depends on</td>
</tr>
</tbody>
</table>
### Name | Description
--- | ---
**the OS and the version of the OS the agent is running on.**
Possible values:
- **true**: Restart is enabled for this agent.
- **false**: Restart is disabled for this agent.
Data type: Boolean

**name** | Name of the agent.
Data type: String

**number_of_running_checks** | The number of checks the agent is scheduled to run. These checks are a part of the policies scheduled for this agent to run.
Data type: Number

**status** | Status of the agent.
Possible values:
- **0**: Alive/Up – The agent is active.
- **1**: Warning – The agent has not received a keep-alive message in the past few minutes.
- **2**: Down – The agent has not received a keep-alive message in a long time.
- **3**: Restarting – The agent is restarting.
Data type: Number

**up_since** | UTC time since the agent’s status became alive/up. The value is in GlideDateTime format.
Data type: String

**version** | Version of Agent Client Collector the agent is running.
Data type: String

---

**Example: cURL request**
The following example shows how to get agent details.

```
curl "https://instance.service-now.com/api/sn_agent/agents/<agent_id>" \
--request GET \
```
--header "Accept:application/json" \n--user 'username':'password'

Output:

```
{
    "name": "WIN-V26KAP?PI2G",
    "status": 2,
    "agent_id": "074b14e2eb3ce9d4",
    "ip_address": "10.196.55.14",
    "number_of_running_checks": 11,
    "data_collection": 0,
    "is_restart_enabled": true,
    "is_duplicate": false,
    "up_since": "2021-03-31 12:02:17",
    "version": "2.3.0"
}
```

**Agent Client Collector - GET /agents/{agent_id}/data/off**

Disables data collection for a specified agent in the up/alive state.

To determine if an agent’s data collection is on or off, run the GET /agents/{agent_id} endpoint.

**URL format**

/api/sn_agent/agents/{agent_id}/data/off

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent_id</td>
<td>Unique ID of an agent listed in the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table. For a list of agent IDs and other details, run the GET /agents/list endpoint. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>403</td>
<td>The user does not have the agent_client_collector_admin role.</td>
</tr>
<tr>
<td>404</td>
<td>Agent not found or is not in the up/alive state.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>Message containing operation success or failure results.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>
Example: cURL request

The following example shows how to turn off agent data collection.

curl "https://instance.service-now.com/api/sn_agent/agents/<agent_id>/data/off" \
--request GET \
--header "Accept:application/json" \
--user 'username':'password'

Output:

{
  "message": "Data Collection Disabled For Agent With ID: <agent_id>"
}

Agent Client Collector - GET /agents/{agent_id}/data/on

Enables data collection for a specified agent in the up/alive state.

To determine if an agent’s data collection is on or off, run the GET /agents/ {agent_id} endpoint.

URL format

/api/sn_agent/agents/{agent_id}/data/on

Supported request parameters

<table>
<thead>
<tr>
<th>Path parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>------</td>
</tr>
<tr>
<td>agent_id</td>
</tr>
<tr>
<td>Data type: String</td>
</tr>
</tbody>
</table>

<table>

<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>
Example: cURL request
The following example shows how to turn on agent data collection.

```
curl "https://instance.service-now.com/api/sn_agent/agents/<agent_id>/data/on" \
--request GET \
--header "Accept:application/json" \
--user 'username':'password'
```

Output:

```
{
  "message": "Data Collection Enabled For Agent With ID: <agent_id>"
}
```

Agent Client Collector - GET /agents/{agent_id}/discovery
Runs a discovery check to locate CIs related to an agent. The specified agent
must be in alive/up status.

URL format
/api/sn_agent/agents/{agent_id}/discovery

Supported request parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent_id</td>
<td>Unique ID of an agent listed in the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table. For a list of agent IDs and other details, run the GET /agents/list endpoint. Data type: String</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

Example: cURL request

The following example shows how to run discovery on an agent with alive/up status.
curl "https://instance.service-now.com/api/sn_agent/agents/<agent_id>/discovery" \
  --request GET \
  --header "Accept:application/json" \
  --user 'username':'password'

Output:

{
  "message": "Running Discovery For Agent With ID: <agent_id>"
}

Agent Client Collector - GET /agents/check_defs/{check_def_id}
Gets a specified check definition with details.

URL format
@api/sn_agent/agents/check_defs/{check_def_id}

Supported request parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check_def_id</td>
<td>Sys_id of the check definition listed in the Check Definitions [sn_agent_check_def] table.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X-Include-Check-Params</td>
<td>Flag that indicates whether existing check parameter details are returned. Information for each standard and secure check parameter is included in a JSON object. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Return check parameter details.</td>
</tr>
<tr>
<td></td>
<td>• false: Do not return check parameter details.</td>
</tr>
</tbody>
</table>

**background**  
Flag that indicates whether this check definition is a background check. A background check is a check which the agent starts execution of and doesn't wait for it to finish running.  
Valid values:  
- **true**: This check definition is a background check.  
- **false**: This check definition is not a background check.  
  Data type: Boolean

**check_group**  
Group specified for this check definition.  
Data type: String

**check_type**  
Type of check.  
Possible values:  
- **Events** – Check results are transformed into an Event Management event.  
- **Metrics** – Values from the check result are transformed to metrics.  
  Data type: String

**command**  
Command that the Agent Client Collector executes.  
Data type: String

**error**  
Message if there is an error. Null otherwise.  
Data type: String

**name**  
Name of the check.
<table>

**Example: cURL request**

The following example shows how to get information for a specified check definition.

```bash
curl
"https://instance.service-now.com/api/sn_agent/agents/check_defs/94436b237f705300f128134f8dfa91a4" \
--request GET \
--header "Accept:application/json" \
--user 'username':'password'
```

**Output:**

```json
{}
```

</tbody>
</table>
| `background` | Flag that indicates whether this check definition is a background check. A background check is a check which the agent starts execution of and doesn’t wait for it to finish running. Valid values:  
  • true: This check definition is a background check.  
  • false: This check definition is not a background check.  
  Data type: Boolean |
| `check_group`| Group specified for this check definition.  
  Data type: String |
| `check_type` | Type of check. Possible values:  
  • Events – Check results are transformed into an Event Management event.  
  • Metrics – Values from the check result are transformed to metrics.  
  Data type: String |
| `command`    | Command that the Agent Client Collector executes. |

```json
[

### Name | Description
---|---
secure_params.order | Order in which the parameter is sent to the check command/script. 
| Data type: Number 
secure_params.sys_id | Sys_id of the secure parameter listed in the Check Secure Parameter Definitions [sn_agent_check_secure_param_def] table. 
| Data type: String 
sys_id | Sys_id of the check definition listed in the Check Definitions [sn_agent_check_def] table. 
| Data type: String 
timeout | Timeout in seconds. 
| Data type: Number

**Example: cURL request**
The following example shows how to retrieve a list of two check definitions with parameter values.

```bash
curl "https://instance.service-now.com/api/sn_agent/agents/check_defs/list" \
--request GET \
--header "Accept:application/json" \
--user 'username':'password'
```

**Output:**
```
{
  "check_definitions": [
    {
      "name": "checks_api_test",
      "command": "echo hello",
      "plugins": [],
      "timeout": 9,
      "proxy_valid": true,
      "background": false,
      "check_type": "TestCheck",
      "check_group": "computer",
      "sys_id": "7f1f9026dba530106f4810284b96194f",
      "params": [],
      "secure_params": [
```
Agent Client Collector - GET /agents/exec/background/stop/{request_id}

Stops a background check.

To start a background check, use the POST /agents/check_defs/{check_def_id}/run API.
**URL format**

/api/sn_agent/agents/exec/background/stop/{request_id}

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request_id</td>
<td>The ID of a background check request generated by running the POST /agents/check_defs/{check_def_id}/run API.</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Example: cURL request

The following example shows how to stop a background check.

```
curl
   "https://instance.service-now.com/api/sn_agent/agents/exec/background/stop/02359174db2a30108a0751ff3961997"
   --request GET
   --header "Accept:application/json"
   --user 'username':'password'
```

Agent Client Collector - GET /agents/exec/run/{request_id}

Gets status of the request with the given ID.

**URL format**

/api/sn_agent/agents/exec/run/{request_id}

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request_id</td>
<td>The ID of a background check request generated by running the POST /agents/check_defs/{check_def_id}/run API.</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

### Example: cURL request

The following example shows how to get the status of a request.

```
curl
"https://instance.service-now.com/api/sn_agent/agents/exec/run/12fed13cdb2a30108a0751f4f3961981" \ 
--request GET 
```
Agent Client Collector - GET /agents/exec/test/{test_result_id}

Gets the test check status of the given test result.

URL format

/api/sn_agent/agents/exec/test/{test_result_id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>test_result_id</td>
<td>A test result ID generated by creating a test check request.</td>
</tr>
</tbody>
</table>

Query parameters

</tbody>
</table>

Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
</table>
| status     | Status of the test results. Possible values:  
• 0: Pending  
• 1: In progress  
• 2: Complete  
• 3: No test result with given ID  
Data type: String |
| output     | Output describing the status.  
Data type: String |

Example: cURL request

The following example shows how get result status of a completed test check request.
curl
  "https://instance.service-now.com/api/sn_agent/agents/check_instances/99e12466dba530106f4810284b961976/test"
  --request POST
  --header "Accept:application/json"
  --user 'username': 'password'

Agent Client Collector - GET /agents/list

Gets a list of agents with related information.

URL format
/api/sn_agent/agents/list

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
<tr>
<td>X-Limit</td>
<td>Restricts results to a maximum number of agents. Use null or undefined for both if they are not required. Default/Max: 20,000. Data type: Number</td>
</tr>
</tbody>
</table>

### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>403</td>
<td>The user does not have the agent_client_collector_user role.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Array&gt;</td>
<td>Array of JSON objects containing extended agent information.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>[</td>
</tr>
<tr>
<td></td>
<td>&quot;agent_id&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;data_collection&quot;: Number,</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>agent_id</td>
<td>ID of the agent as submitted.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>data_collection</td>
<td>Data collection indicates whether scheduled checks are to be run. These checks are a part of the policies scheduled for this agent to run. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• 0: On – Checks run as scheduled.</td>
</tr>
<tr>
<td></td>
<td>• 1: Off (manual) – Checks have been disabled manually.</td>
</tr>
<tr>
<td></td>
<td>• 2: Off (auto) – Checks have been disabled automatically due to high CPU consumption by the agent.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>ip_address</td>
<td>Agent IP address.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>is_duplicate</td>
<td>Flag that indicates whether this agent is a duplicate of another. There should be only a single agent on a given host. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: The agent has the same host as an Alive/Up agent with a different agent ID. Turn off or uninstall the duplicate</td>
</tr>
<tr>
<td></td>
<td>• false: This agent has no duplicates in the Alive/Up state.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| is_restart_enabled    | Flag that indicates whether restart is enabled. Agent restart is not configurable. It depends on the OS and the version of the OS the agent is running on. Possible values:  
  - true: Restart is enabled for this agent.  
  - false: Restart is disabled for this agent.  
  Data type: Boolean |
| name                  | Name of the agent.  
  Data type: String |
| number_of_running     | The number of checks the agent is scheduled to run. These checks are a part of the policies scheduled for this agent to run.  
  Data type: Number |
| status                | Status of the agent. Possible values:  
  - 0: Alive/Up – The agent is active.  
  - 1: Warning – The agent has not received a keep-alive message in the past few minutes.  
  - 2: Down – The agent has not received a keep-alive message in a long time.  
  - 3: Restarting – The agent is restarting.  
  Data type: Number |
| up_since              | UTC time since the agent’s status became alive/up. The value is in GlideDateTime format.  
  Data type: String |
| version               | Version of Agent Client Collector the agent is running.  
  Data type: String |

**Example: cURL request**

The following example shows how to restrict results by query and number. The query returns all agents that are not in the down state with a maximum of two results.
curl "https://instance.service-now.com/api/sn_agent/agents/list" \
  --request GET \
  --header "Accept:application/json" \
  --header "X-Enc-Query: agent_extended_info.status!=2" \
  --header "X-Limit: 2" \
  --user 'username':'password'

Output:

```
{
  "agents": [
    {
      "name": "007-175",
      "status": 0,
      "agent_id": "007-175",
      "ip_address": "11.222.63.66",
      "number_of_runningChecks": 0,
      "data_collection": 0,
      "is_restart_enabled": false,
      "is_duplicate": false,
      "up_since": "2021-03-24 14:36:45",
      "version": "2.4.0"
    },
    {
      "name": "win2016-dc-64bit",
      "status": 0,
      "agent_id": "007-64",
      "ip_address": "10.222.333.42",
      "number_of_runningChecks": 1,
      "data_collection": 0,
      "is_restart_enabled": true,
      "is_duplicate": false,
      "up_since": "2021-03-24 11:04:38",
      "version": "2.4.0"
    }
  ]
}
```

Example: cURL request

The following example shows how to list every agent in the system. This example uses no query and no maximum number of results.

```
curl "https://instance.service-now.com/api/sn_agent/agents/list" \
  --request GET \
```
Agent Client Collector - GET /agents/{agent_id}/log

Requests the log of a specified agent with alive/up status.

ℹ️ **Note:** To retrieve the log and check its progress, pass the request ID returned to the GET /agents/log/{request_id}/ endpoint.

**URL format**

/api/sn_agent/agents/{agent_id}/log

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent_id</td>
<td>Unique ID of an agent listed in the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table. For a list of agent IDs and other details, run the GET /agents/list endpoint. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports <code>application/json</code>.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>403</td>
<td>The user does not have the agent_client_collector_admin role.</td>
</tr>
<tr>
<td>404</td>
<td>Agent not found or is not in the up/alive state.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request_id</td>
<td>Sys_id of a request in the Agent Client Collector Requests [sn_agent_request] table.</td>
</tr>
<tr>
<td></td>
<td>You can use this ID to retrieve the log and check its progress with the GET /agents/log/{request_id}/ endpoint.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Example: cURL request

The following example shows how to get a log request ID.

```bash
curl "https://instance.service-now.com/api/sn_agent/agents/<sys_id>/log" \
--request GET \
--header "Accept:application/json" \
--user 'username':'password'
```
Output:

```
"request_id": "<sys_id>"
```

**Agent Client Collector - GET /agents/log/{request_id}/**

Checks the status of a grab log request.

Detects changes in the log retrieving request sent with GET /api/sn_agent/agents/{agent_id}/log.

**URL format**

/api/sn_agent/agents/log/{request_id}/

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>request_id</td>
<td>Sys_id of a request in the Agent Client Collector Requests [sn_agent_request] table.</td>
</tr>
<tr>
<td></td>
<td>For the request id, run GET /api/sn_agent/agents/{agent_id}/log.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>

</table>

Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Properties</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>output</td>
<td>Information describing the status.</td>
</tr>
</tbody>
</table>

Example: cURL request

The following example shows how to use a request ID to get the status of a grab log request.

curl "https://instance.service-now.com/api/sn_agent/agents/log/<request_ID>" \
--request GET \
Output:

```json
{
  "output": "SensuSnReadFile OK:
  \{"component":\"agent\",\"level\":\"info\",\"msg\":\"Agent Protection: cpu of all checks: 0\",\"time\":\"2021-04-05T00:21:41-07:00\"\},...
}
```

Agent Client Collector - GET /agents/policies/list

Gets a list of policies that are in published or unpublished draft state.

**URL format**

/api/sn_agent/agents/policies/list

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>

**Example: cURL request**

The following example shows how to restrict results by query and number. The query returns all active policies and the ID of the associated agent.

```bash
curl "https://instance.service-now.com/api/sn_agent/agents/policies/list" \
--request GET \
```
--header "Accept: application/json"
--header 'X-Enc-Query: active=true'
--header 'X-Include-Checks-And-Agents: true'
--user 'username': 'password'

Output:

```json
{
  "policies": [{
    "name": "Basic Discovery",
    "sys_id": "68bfd27c536113006dfeddeff7b12be",
    "active": "true",
    "interval": "43200",

}
```
Example: Python request

The following example shows how to get policy, check, and parameter information for a policy called Apache Metrics.

```python
import requests
data = { 'username' : 'username', 'password' : 'password' }
url = "https://instance.service-now.com/api/sn_agent/agents/policies/list"
payload = {}
headers = {
    'X-Include-Check-Params': 'true',
    'X-Enc-Query': 'sys_name=Apache Metrics'
}
response = requests.request("GET", url, headers=headers, data = payload)
print(response.text.encode('utf8'))
```

Output:

```json
{
    "policies": [
        {
            "name": "Apache Metrics",

<tbody>
<tr>
<td>message</td>
<td>Message containing operation success or failure results.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>
Example: cURL request

The following example shows how to activate a policy.

```
curl "https://instance.service-now.com/api/sn_agent/agents/policy/activate/<sys_id>" \
  --request GET \
  --header "Accept:application/json" \
  --user 'username' : 'password'
```

Output:

```
{
  "message": "Operation was successful"
}
```

Agent Client Collector - GET /agents/policy/deactivate/{policy_id}

Deactivates a published policy.

For a list of published policies, use GET /agents/policies/list. This endpoint only supports sys_ids in which the value of the policy's publish_status property is Published or Published*.

**URL format**

/api/sn_agent/agents/policy/activate/{policy_id}

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>403</td>
<td>The user does not have the <code>agent_client_collector_admin</code> role.</td>
</tr>
<tr>
<td>404</td>
<td>No record found with the provided <code>sys_id</code>.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>Message containing operation success or failure results. Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

The following example shows how to publish a policy.

```bash
curl "https://instance.service-now.com/api/sn_agent/agents/policy/publish/<sys_id>" \
--request GET \
--header "Accept:application/json" \
--user 'username' : 'password'
```

**Output:**

```json
{
   "message": "Operation was successful"
}
```

**Agent Client Collector - GET /agents/policy/sandbox_from_published/{policy_id}**

Gets the sandbox copy of a published policy and provides policy details.

Use the sandbox copy to make updates to a policy and publish. You can use the `sys_ids` in the response body to work with the following endpoints:

- **POST /agents/update/policy/{policy_id}**
- **POST /agents/update/check/{check_id}**
• POST /agents/update/check_param/{param_id}
• POST /agents/update/check_secure_param/{param_id}

For a list of published policies, use GET /agents/policies/list. This endpoint only supports sys_ids in which the value of the policy’s publish_status property is Published or Published*.

URL format
/api/sn_agent/agents/policy/sandbox_from_published/{policy_id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policy_id</td>
<td>Sys_id of the published policy listed in the Policies [sn_agent_policy] table. Data type: String</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>checks.command</td>
<td>Command that the Agent Client Collector executes. Parameter taken from a template or monitored CI.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If <code>auto_generate</code> is true, this property is automatically populated with the prefix and flags of the active parameters listed in the <code>parameters</code> object.</td>
</tr>
<tr>
<td>checks.command_prefix</td>
<td>If the <code>auto_generate</code> property is true, this command is used for automatic generation. The prefix consists of any portion of the command which is static (does not change), such as the script name.</td>
</tr>
<tr>
<td>checks.event_status_change_threshold</td>
<td>The number of consecutive times that a check's response status must happen before a new event is sent. Returns null if not set. For example, if this value is 3, a check whose response status changes from OK to Error generates a new event with an Error status after the third consecutive occurrence of the status change.</td>
</tr>
<tr>

<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>checks.event_status_repair_threshold</td>
<td>The number of consecutive times that a check's response status must improve to close the previous event. Returns null if not set. For example, if this value is 3, a check whose response status changes from Error to OK closes the previous event and generates a new event with an OK status after the third consecutive occurrence of the status change.</td>
</tr>
<tr>
<td>checks.interval</td>
<td>The amount of time in seconds to wait between check executions. For example, a value of 60 means that the check runs every 60 seconds.</td>
</tr>
<tr>
<td>checks.name</td>
<td>Name of the check.</td>
</tr>
<tr>
<td>checks.sys_id</td>
<td>Sys_id of the check listed in the Check Instances [sn_agent_check] table. The POST /agents/update/check/{check_id} endpoint takes this value to update the sandbox copy.</td>
</tr>
<tr>
<td>checks.timeout</td>
<td>The amount of time, in seconds, after which the check execution stops when no output is returned. For example, a value of 60 means that when the check execution doesn’t return a value for 60 seconds, the execution stops.</td>
</tr>
<tr>
<td>cred_alias</td>
<td>Name listed in the Credentials [discovery_credentials] table.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credential_alias</td>
<td>Sys_id of the credential alias in the Connection &amp; Credential Aliases [sys_alias] table. Data type: String</td>
</tr>
<tr>
<td>filter</td>
<td>Filter restricting the policy's checks to monitor only the specified criteria. Data type: String</td>
</tr>
<tr>
<td>interval</td>
<td>The amount of time in seconds to wait between policy checks. For example, a value of 60 means that the check runs every 60 seconds. <strong>Note:</strong> The value of the checks.interval property overrides the value configured in this field. Data type: Number</td>
</tr>
<tr>
<td>monitored_ci_group</td>
<td>Name of the CMDB groups associated with the policy. This CMDB is listed in the CMDB Groups [cmdb_group] table. This field is only applied if the value of the monitored_ci_type_group property is true. Data type: String</td>
</tr>
<tr>
<td>monitored_ci_script</td>
<td>Script for monitoring CIs. This field is only applied if the value of the policies.monitored_ci_type_script property is true. Data type: String</td>
</tr>
<tr>
<td>monitored_ci_type_filter</td>
<td>Flag that indicates whether filtering by CI type is enabled. The CI type is listed in the table property. Valid values:</td>
</tr>
</tbody>
</table>

|                     | Data type: String                                                                                                                                                                                             |
**Property** | **Description**  
--- | ---  
sys_updated_on | Date and time that the policy was last updated.  
Data type: String  
table | Monitored CI-type field on the policy. This field is only applied if monitored_ci_type_filter is true.  
Data type: String  

**Example: cURL request**

The following shows how to get information of the Docker Container Metrics policy.

```bash
curl  
"https://instance.service-now.com/api/sn_agent/agents/policy/sandbox_from_published/<sys_id>" 
--request GET 
--header "Accept:application/json" 
--user 'username':'password'
```

**Output:**

```
{
  "name": "Docker Container Metrics",
  "sys_id": "b01e609a1b9fe4943e7f0b05464bcb91",
  "active": "false",
  "interval": "60",
  "sys_updated_on": "2021-04-05 19:52:28",
  "monitored_ci_type_filter": "true",
  "filter": "operational_status=1",
  "table": "cmdb_ci_docker_container",
  "monitored_ci_type_script": "false",
  "monitored_ci_script": "/*
  Provide a script to get monitored CI type.",
  "monitored_ci_type_group": "false",
  "monitored_ci_group": "null// group name as seen in cmdb_group table",
  "cred_alias": "null// credential name as seen in discovery_credentials table",
  "credential_alias": "null// credential alias sys id as seen in sys_alias table",
  "publish_status": "Published",
  "checks": [
    
    {
      "name": "container.docker.metrics-docker",
      "sys_id": "701e609a1b9fe4943e7f0b05464bcb94",
```
Agent Client Collector - GET /agents/{agent_id}/restart

Restarts a specified agent with alive/up status.

If Agent Client Collector performance issues occur, you can restart the agent. Manual restart is supported in the following environments:

- Linux-based agents using systemd
- Windows agents
**URL format**

/api/sn_agent/agents/{agent_id}/restart

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent_id</td>
<td>Unique ID of an agent listed in the Agent ID column of the Agent Client Collectors [sn_agent_cmdb_ci_agent] table. For a list of agent IDs and other details, run the <code>GET /agents/list</code> endpoint. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

**Request body parameters (JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).

**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports <code>application/json</code>.</td>
</tr>
</tbody>
</table>

**Response headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>403</td>
<td>The user does not have the agent_client_collector_admin role.</td>
</tr>
<tr>
<td>404</td>
<td>No record found with the provided sys_id or this agent does not support restart.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>Message containing operation success or failure results. Data type: String</td>
</tr>
</tbody>
</table>

Example: cURL request

The following example shows how to restart an agent.

```bash
curl "https://instance.service-now.com/api/sn_agent/agents/<agent_id>/restart" \
    --request GET \
    --header "Accept:application/json" \
    --user 'username':'password'
```

Output:

```json
{
   "message": "Restarting Agent With ID: <agent_id>"
}
```

Agent Client Collector - POST /agents/check_defs/{check_def_id}/run

Runs a check against the given configuration item.

To stop a background check, use the request ID provided in the GET /agents/exec/background/stop/{request_id} API.
URL format
/api/sn_agent/agents/check_defs/{check_def_id}/run

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check_def_id</td>
<td>Sys_id of a check definition in the Check Definitions [sn_agent_check_def] table.</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| params | Map of parameter names and values. These settings can be used to override the parameter records of the check definition and its specified values.  
"params": { 
    "<parameter name>": "String" 
}  
Data type: Object |
| priority | Priority of the request to be set on the ECC queue. Possible values:  
• 0: interactive  
• 1: expedited  
• 2: standard  
Data type: Number |
| query | Encoded query for retrieving the GlideRecord from the table specified in the table property.  
Data type: String |
| table | Name of the cmdb_ci table for this background check. |
Request body parameters (JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>timeout</td>
<td>Value of the timeout for the request in seconds.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>The is an error in the arguments provided in the request body.</td>
</tr>
<tr>
<td>404</td>
<td>The check definition with the ID provided is not found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>
Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>Sys_id of the generated background check request.</td>
</tr>
</tbody>
</table>

Example: cURL request

The following example shows how to run a background check and get its request ID.

```
curl
  "https://instance.service-now.com/api/sn_agent/agents/check_defs/a90d3c361be1301060d2773ad544cb6f/run" 
--request POST 
--header "Accept:application/json" 
--header "Content-Type:application/json" 
--data "{"table":"sn_agent_check_def"}"
--user 'username': 'password'
```

Output:

```
{
  "request_id": "278c0170db2a30108a0751f4f3961926"
}
```

Agent Client Collector - POST /agents/check_defs/{check_def_id}/test

Enables building test check requests on check definitions.

Use this API for the following tasks:

- Set the check definition to test
- Set the configuration item to run the test against

You can also specify one of the following identifiers to use during the test:

- Credential sys_id
- Credential alias id
- Credential name

URL format

/api/sn_agent/agents/check_defs/{check_def_id}/test
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check_def_id</td>
<td>Sys_id of the check definition listed in the Check Definitions [sn_agent_check_def] table.</td>
</tr>

</tr>
</thead>
<tbody>
<tr>
<td>result_id</td>
<td>Sys_id of the test result record.</td>
</tr>
</tbody>
</table>

Agent Client Collector - POST /agents/check_instances/{check_instance_id}/test

Enables building test check requests on check instances.

Use this API for the following tasks:

- Set the check instance to test
- Set the configuration item to run the test against

You can also specify one of the following identifiers to use during the test:

- Credential sys_id
- Credential alias id
- Credential name

URL format

/api/sn_agent/agents/check_instances/{check_instance_id}/test
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check_instance_id</td>
<td>Sys_id of the check definition listed in the Check Definitions [sn_agent_check_def] table.</td>
</tr>
</tbody>
</table>

### Query parameters

</thead>
<tbody>
<tr>
<td>result_id</td>
<td>Sys_id of the test result record.</td>
</tr>
</tbody>
</table>

Agent Client Collector - POST /agents/update/check/{check_id}

Updates a selected policy check.

To retrieve the properties of a policy sandbox copy, use GET /agents/policy/sandbox_from_published/{policy_id}.

URL format

/api/sn_agent/agents/update/check/{check_id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check_id</td>
<td>Sys_id of a policy check sandbox copy in the Check Instances [sn_agent_check] table. Data type: String</td>
</tr>
</tbody>
</table>
## Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

## Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>Flag that indicates whether the policy check is active. Valid values: • true: Policy check is active. • false: Policy check is inactive. Data type: Boolean</td>
</tr>
<tr>
<td>auto_generate</td>
<td>Flag that indicates whether to automatically generate the command with the command_prefix value. Valid values: • true: Automatically populate the command property with active parameter values. • false: Command is not automatically generated. Data type: Boolean</td>
</tr>
<tr>
<td>check_type</td>
<td>Check type specifying the monitoring option. Possible values: • Discovery: Check that locates CIs related to the agent. • Events: The check's result is transformed into an Event Management event. • Metrics: The values from the check result are transformed to metrics. Data type: String</td>
</tr>
</tbody>
</table>
## Request body parameters (JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>command</strong></td>
<td>Command that the Agent Client Collector executes. Parameter taken from a template or monitored CI.</td>
</tr>
<tr>
<td></td>
<td>⚠️ <strong>Note:</strong> If <code>auto_generate</code> is true, this property is automatically populated with the prefix and flags of the active parameters listed in the <code>parameters</code> object.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td><strong>command_prefix</strong></td>
<td>If the <code>auto_generate</code> property is true, this command is used for automatic generation. The prefix consists of any portion of the command which is static (does not change), such as the script name.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td><strong>event_status_change_threshold</strong></td>
<td>The number of consecutive times that a check's response status must happen before a new event is sent. Returns null if not set. For example, if this value is 3, a check whose response status changes from OK to Error generates a new event with an Error status after the third consecutive occurrence of the status change.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td><strong>event_status_repair_threshold</strong></td>
<td>The number of consecutive times that a check's response status must improve to close the previous event. Returns null if not set. For example, if this value is 3, a check whose response status changes from Error to OK closes the previous event and generates a new event with an OK status after the third consecutive occurrence of the status change.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
</tbody>
</table>
Request body parameters (JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>interval</td>
<td>The amount of time in seconds to wait between check executions. For example, a value of 60 means that the check runs every 60 seconds. Data type: Number</td>
</tr>
<tr>
<td>name</td>
<td>Name of the check. Data type: String</td>
</tr>
<tr>
<td>timeout</td>
<td>The amount of time, in seconds, after which the check execution stops when no output is returned. For example, a value of 60 means that when the check execution doesn’t return a value for 60 seconds, the execution stops. Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>403</td>
<td>The user does not have the agent_client_collector_admin role.</td>
</tr>
<tr>
<td>404</td>
<td>No record found with the provided sys_id.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>Message containing operation success or failure results.</td>
</tr>
</tbody>
</table>

Data type: String

### Example: cURL request

The following example shows how to update the event change and repair properties of a policy check.

```bash
curl "https://instance.service-now.com/api/sn_agent/agents/update/check/<check_sys_id>" \
--request POST \
--header "Accept:application/json" \
--header "Content-Type:application/json" \
--data "{
"event_status_change_threshold" : "2",
"event_status_repair_threshold" : "1"
}" \
--user 'username':'password'
```

Output:

```json
{
"message": "Operation was successful"
}
```

### Agent Client Collector - POST /agents/update/check_def_params/

{check_def_param_id}

Enables changing one or more field values of a specified check parameter.
**URL format**

/api/sn_agent/agents/update/check_def_params/{check_def_param_id}

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check_def_param_id</td>
<td>Sys_id of the check parameter listed in the Check Parameter Definitions [sn_agent_check_param_def] table. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>Flag that indicates whether the check parameter is active. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: The check parameter is active.</td>
</tr>
<tr>
<td></td>
<td>• false: The check parameter is inactive.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>default_value</td>
<td>Specifies the default value for this check parameter.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>mandatory</td>
<td>Flag that indicates whether the check parameter is required. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: The check parameter is required.</td>
</tr>
<tr>
<td></td>
<td>• false: The check parameter is optional.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>name</td>
<td>Name of the check parameter.</td>
</tr>
</tbody>
</table>
Request body parameters (JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Note:** Refer to the data dictionary for a comprehensive list of Check Definition fields and types.

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports <strong>application/json</strong>.</td>
</tr>
</tbody>
</table>

#### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

#### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>404</td>
<td>The check parameter was not found with sys_id provided.</td>
</tr>
<tr>
<td>500</td>
<td>Error updating the check parameter.</td>
</tr>
</tbody>
</table>
Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Success or error message.</td>
</tr>
</tbody>
</table>

Example: cURL request

The following example shows how to activate a check parameter.

curl
"https://instance.service-now.com/api/sn_agent/agents/update/check_def_params/02d89bb01b307490f271ea42b24bcb63" \ 
--request POST \ 
--header "Accept:application/json" \ 
--header "Content-Type:application/json" \ 
--data "{"active":true}" \ 
--user 'username': 'password'

Output:

"message": "Check Definition Parameter Updated Successfully"

Agent Client Collector - POST /agents/update/check_def_secure_params/
{check_def_secure_param_id}

Enables changing one or more field values of a specified check secure parameter.

URL format

/api/sn_agent/agents/update/check_def_secure_params/
{check_def_secure_param_id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check_def_secure_param_id</td>
<td>Sys_id of the secure parameter listed in the Check Secure Parameter Definitions [sn_agent_check_secure_param_def] table. Data type: String</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>Flag that indicates whether the secure parameter is active. Valid values: • true: The secure parameter is active. • false: The secure parameter is inactive. Data type: Boolean</td>
</tr>
<tr>
<td>name</td>
<td>Name of the secure parameter. Data type: String</td>
</tr>
<tr>
<td>order</td>
<td>Order in which the parameter is sent to the check command/script. Data type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>

</table>

Example: cURL request

The following example shows how to deactivate a check definition.

```cURL
curl "https://instance.service-now.com/api/sn_agent/agents/update/check_defs/99e12466dba530106f4810284b961976" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --data "{"active":false}" \
  --user 'username':'password'
```

Output:

"message": "Check Definition Updated Successfully"

Agent Client Collector - POST /agents/update/check_param/{param_id}

Updates a selected policy check parameter.

To retrieve the properties of a policy sandbox copy, use GET /agents/policy/sandbox_from_published/{policy_id}.

URL format

/api/sn_agent/agents/update/check_param/{param_id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports <code>application/json</code>.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>403</td>
<td>The user does not have the <code>agent_client_collector_admin</code> role.</td>
</tr>
<tr>
<td>404</td>
<td>No record found with the provided <code>sys_id</code>.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>Message containing operation success or failure results. Data type: String</td>
</tr>
</tbody>
</table>
Example: cURL request

The following example shows how to update several properties of a policy check parameter.

```bash
curl
  "https://instance.service-now.com/api/sn_agent/agents/update/check_param/<param_sys_id>" \
--request POST \
--header "Accept:application/json" \
--header "Content-Type:application/json" \
--data "{
  "flag" : "-d",
  "mandatory" : "true",
  "name" : "scheme2",
  "value" : "120",
  "value_required" : "false"
}" \
--user 'username':'password'
```

Output:

```
{
  "message": "Operation was successful"
}
```

Agent Client Collector - POST /agents/update/check_secure_param/{param_id}

Updates a selected policy check secure parameter.

To retrieve the properties of a policy sandbox copy, use GET /agents/policy/sandbox_from_published/{policy_id}.

**URL format**

/api/sn_agent/agents/update/check_secure_param/{param_id}

**Supported request parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>param_id</td>
<td>Sys_id of the policy check secure parameter sandbox copy in the Check Secure Parameter [sn_agent_check_secure_param] table. Data type: String</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| active | Flag that indicates whether the check secure parameter is active.  
Valid values:
  • true: The check secure parameter is active.
  • false: The check secure parameter is inactive.  
Data type: Boolean |
| name | Name of the secure parameter.  
Data type: String |
| order | Order in which the parameter is sent to the check command/script.  
Data type: Number |

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<tr>
<td>404</td>
<td>No record found with the provided sys_id.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>Message containing operation success or failure results. Data type: String</td>
</tr>
</tbody>
</table>

### Example: cURL request

The following example shows how to update the name and filter properties/fields of a policy.

```bash
curl "https://instance.service-now.com/api/sn_agent/agents/update/policy/<policy_sys_id>" 
  --request POST 
  --header "Accept:application/json" 
  --header "Content-Type:application/json" 
  --data "{
    "name": "new policy name",
    "filter": "operational_status=1"
  }" 
  --user 'username': 'password'
```

Output:

```json
{
  "message": "Operation was successful"
}
```

### Aggregate API

The Aggregate API allows you to compute aggregate statistics about existing table and column data.
For Aggregate API requests, you must have read access for all records in the table you query. If an ACL prevents the requesting user from accessing any record in the table, the request returns a 403 Forbidden error.

**Aggregate - GET /now/stats/{tableName}**

Retrieves records for the specified table and performs aggregate functions on the returned values.

You can specify which aggregate functions to perform by using either the `sysparm_<aggregate>_fields` parameter or `sysparm_having=<aggregate>^field^operator^value` parameter, substituting `<aggregate>` for one of these aggregate functions:

- `avg`
- `max`
- `min`
- `sum`

**URL format**

Versioned URL: `/api/now/{api_version}/stats/{tableName}`
Default URL: `/api/now/stats/{tableName}`

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>api_version</code></td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td><code>tableName</code></td>
<td>Name of the table for which to retrieve records. Data type: String</td>
</tr>
</tbody>
</table>
### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>An alternative to using the <code>sysparm_query</code> parameter. You can filter a query using key-value pairs where the key is the name of a field. For example, instead of using the parameter <code>&amp;sysparm_query=active=true</code>, you can use <code>&amp;active=true</code>. You can use the display value when the field is a choice or reference type field, such as <code>&amp;state=closed</code> instead of <code>&amp;state=7</code>. To specify multiple key-value pairs, separate each with an ampersand, such as <code>&amp;active=true&amp;assigned_to=john.smith</code>. Data type: String</td>
</tr>
<tr>
<td>sysparm_&lt;aggregate&gt;_fields</td>
<td>List of fields on which to perform each aggregate operation. You can specify multiple fields by separating each with a comma. For example, to get the average values from the duration and priority fields, use <code>sysparm_avg_fields=duration,priority</code>. Note: Specify this parameter, the <code>sysparm_count</code> parameter, or both for your query to return meaningful results. If neither parameter is passed, no aggregate operation is performed. Data type: String</td>
</tr>
<tr>
<td>sysparm_count</td>
<td>Flag that determines whether to return the number of records returned by the query. Note: Specify this parameter, the <code>sysparm_&lt;aggregate&gt;_fields</code> parameter, or both for your query to return meaningful results. If neither parameter is passed, no aggregate operation is performed. Data type: String</td>
</tr>
<tr>
<td>sysparm_display_value</td>
<td>Data retrieval operation when grouping by reference or choice fields. Based on this value, the query returns either the display value, the actual value in the database, or both. • <strong>true</strong>: Returns display values for all fields. • <strong>false</strong>: Returns actual values from the database. If a value is not specified, this parameter defaults to false. • <strong>all</strong>: Returns both actual and display values.</td>
</tr>
</tbody>
</table>
## Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_group_by</td>
<td>Fields by which to group the returned data. You can specify multiple fields by separating each field with a comma, such as <code>sysparm_group_by=priority, state</code>.</td>
<td>String</td>
</tr>
<tr>
<td>sysparm_having</td>
<td>Additional query that enables you to filter the data based on an aggregate operation. The value for this parameter must follow the syntax <code>aggregate^field^operator^value</code>, such as <code>count^priority^&gt;^3</code> to obtain the number of records within the query results with a priority greater than 3. You can specify multiple queries by separating each with a comma, such as <code>count^state^=^1, avg^priority^&gt;^3</code>.</td>
<td>String</td>
</tr>
<tr>
<td>sysparm_orderby</td>
<td>List of values by which to order grouped results. You can specify an order using a field or an aggregate. For example, if you specify <code>sysparm_orderby=AVG^state</code>, groups of results with lower average state values are returned first. You can also order by <code>COUNT</code> to arrange groups of records by the number of records in each group. When you specify an order, groups are ordered in ascending order by default. Use <code>^DESC</code> to sort in descending order, such as <code>sysparm_orderby=state^DESC</code>.</td>
<td>String</td>
</tr>
<tr>
<td>sysparm_query</td>
<td>An encoded query.</td>
<td>String</td>
</tr>
</tbody>
</table>

For example:

```plaintext
(sysparm_query=active=true)
(sysparm_query=caller_id=javascript:gs.getUserID()^active=true)
```
Request body parameters (XML or JSON)

      <avg>
        <business_stc>2037371.0000</business_stc>
        <reassignment_count>1.5000</reassignment_count>
      </avg>
    </stats>
  </result>
  <result>
    <stats>
      <avg>
        <business_stc>1821488.2857</business_stc>
        <reassignment_count>1.1111</reassignment_count>
      </avg>
    </stats>
  </result>
</response>
AI Search External User Mapping API

The AI Search External User Mapping API provides endpoints that enable ingestion of user mapping information from external sources into the ServiceNow® AI Search application's index.

AI Search External User Mapping - POST /ais/external_content/user_mapping/import_multiple/{target_table}

Imports a list of external user mappings into an AI Search user mapping table. Each mapping specifies externally defined user and group aliases for a Now Platform user. AI Search uses these aliases to determine which external document search results the user can view.

To learn how AI Search external content security utilizes external user mappings, see External content security for AI Search.

User and group names in external user mappings should match those specified in security access permissions for external documents ingested via the External Content Ingestion API's POST /ais/external_content/ingestDocument/{schema_table_name} endpoint. For more information on ingesting external documents with security access permissions for externally defined users and groups, see External Content Ingestion API.

To view import histories for external user mapping records imported through this endpoint, navigate to AI Search > External Content > User mapping import history. From a history record, you can view the Import Set [sys_import_set] and Multi Import Set [sys_multi_import_set] records for an import task. Use information from these records to verify that your external user mappings were imported correctly.

**URL format**

Versioned URL: /api/now/{api_version}/ais/external_content/user_mapping/import_multiple/{target_table}

**Supported request parameters**

</tbody>
</table>

**Example: cURL request**

Import externally defined user and group aliases for Now Platform users Beth Anglin and Abel Tuter into an AI Search user mapping table named `x_snc_sharepoint_user_table`.

```
curl -X POST
'https://instance.servicenow.com/api/now/v1/ais/external_content/user_mapping/import_multiple/x_snc_sharepoint_user_table' \
-H 'Accept: application/json' \
-H 'Content-Type: application/json' \
-u 'username': 'password' \
-d '{
  "records": [
    {
      "mapping_value": "beth.anglin@example.com",
      "external_user": [
        "ad\beth-anglin",
        "beth.anglin@sharepoint"
      ],
      "external_group": [
        "itil",
        "itil-admin",
        "itil-dev"
      ]
    },
    {
      "mapping_value": "abel.tuter@example.com",
      "external_user": [
        "ad\abel-tuter",
        "abel.tuter@sharepoint"
      ],
      "external_group": [
        "hr",
        "hr-admin",
        "hr-dev"
      ]
    }
  ]
}
```
The response shows the sys_ids for the generated Import Set and Multi Import Set records.

```json
{
  "import_set_id": "6e9ddb629d987010f877878bd9f0e9dd",
  "multi_import_set_id": "269ddb629d987010f877878bd9f0e9de"
}
```

**Example: cURL request**

Import invalid request containing an empty mapping record.

```cURL
curl 'https://instance.servicenow.com/api/now/v1/ais/external_content/user_mapping/import_multiple/u_ext_content_user_mapping' \   --request POST \   --user 'username': 'password' \   --header 'Accept: application/json' \   --header 'Content-Type: application/json' \   --data '{
  "records": [
    {
      "mapping_value": "beth.anglin@example.com",
      "external_user": [
        "ad\beth-anglin",
        "beth.anglin@sharepoint"
      ],
      "external_group": [
        "reports",
        "reports-admin",
        "reports-dev"
      ]
    },
    {}
  ]
}'
```

The request fails with status 400 and the response indicates the nature of the failure.
Example: Python request

Import external user and group aliases for Now Platform users Beth Anglin and Abel Tuter into an AI Search user mapping table named u_ext_content_user_mapping.

```python
# Need to install requests package for python
import requests
import json

# Set the API endpoint URL for the request
url = "https://instance.servicenow.com/api/now/v1/ais/external_content/user_mapping/import_multiple/u_ext_content_user_mapping"

# Set credentials
user = "username"
pwd = "password"

# Set HTTP headers
headers = {"Accept": "application/json", "Content-Type": "application/json"}

data = json.dumps(
    {
        "records": [
            {
                "mapping_value": "beth.anglin@example.com",
                "external_user": [
                "ad\beth-anglin",
                "beth.anglin@sharepoint"
                ],
                "external_group": [
                "itil",
                "itil-admin",
                "itil-dev"
                ]
            },
            {
                "mapping_value": "abel.tuter@example.com",
                "external_user": [
            ...
```
The response shows the sys_ids for the generated Import Set and Multi Import Set records.

```json
{
    "import_set_id": "3111eb2a9d987010f877878bd9f0e973",
    "multi_import_set_id": "f511eb2a9d987010f877878bd9f0e973"
}
```

**Alarm Management Open API**

Creates or updates data in the Events [em_event] table.

The telecommunications Alarm Management Open API (sn_ind_tmf642) is a ServiceNow® implementation of the TMforum Open API specification. This API is based on TMF642 Alarm Management API REST Specification Release 20, April 2020.

The calling user must have to access the sn_ind_tmf642.alarm_mgmt_integration endpoint.

This API is provided within the sn_ind_tmf642 namespace.
TMforum Open API specification requires a synchronous response for every inbound request it receives. Apply correlation and de-duplication in the source operational support system (OSS) before forwarding payloads to the system.

**Extending the Alarm Management Open API**

The Alarm Management Open API can be extended by editing the AlarmAPIProcessor script include or creating new script includes. Do not edit or create script includes without an understanding of the consequences of the changes.

- **AlarmAPIProcessor**: An empty script include file. Use this file to define any functions that you want to override from AlarmAPIProcessorOOB.

Extend the Alarm Management Open API to make the following customizations.

**Required parameters**

Alarm Management API utilizes JSON schemas to hold required parameters information. These JSON schemas are defined in the TMFAlarmAPIConstants script include. These schemas are used to validate whether request payloads are valid. These schemas are not referenced directly in script includes and are returned by the following methods in the AlarmAPIProcessorOOB script include:

- **getCreateEventSchema**: Returns the validating schema for creating an event.
- **getClearEventSchema**: Returns the validating schema for clearing an event alarm.
- **getPatchEventSchema**: Returns the validating schema for patching an event.

To override existing schemas, define new schemas in the AlarmAPIProcessor script include and override the AlarmAPIProcessorOOB script include methods.

```javascript
var AlarmAPIProcessor = Class.create();
AlarmAPIProcessor.prototype = Object.extendObject(AlarmAPIProcessorOOB, { // Define overriding functions here

    // Define getCreateEventSchema here to override OOTB method in AlarmAPIProcessorOOB
    getCreateEventSchema: function() {
        return JSON.parse(AlarmAPIProcessor.CUSTOMIZED_SCHEMA);
    },
    type: 'AlarmAPIProcessor'
});
```

Request body validation

To perform additional validation on the request body, override AlarmAPIProcessorOOB functions. AlarmAPIProcessorOOB contains the following helper functions that return true by default. These functions are called in TMFAAlarmAPIUtil.

- `verifyCreateEventPayload()` - Called by `processCreateEvent()`.
- `verifyClearEventPayload()` - Called by `processClearEvent()`.
- `verifyPatchEventPayload()` - Called by `processPatchEvent()`.

If a helper function returns false, it stops the API operation. To apply custom validation, override AlarmAPIProcessorOOB helper functions with identically-named function names and parameters in AlarmAPIProcessor. The new AlarmAPIProcessor functions are called by TMFAAlarmAPIUtil to replace the default AlarmAPIProcessorOOB helper functions.

In this example, a function in AlarmAPIProcessor overrides a default function in AlarmAPIProcessorOOB to perform validation on the name attribute.

```javascript
var AlarmAPIProcessor = Class.create();
AlarmAPIProcessor.prototype = Object.extendObject(AlarmAPIProcessorOOB, {
    // Define overriding functions here

    verifyCreateEventPayload: function(eventPayload, apiResponseProcessor){
        // Returning false terminates the POST request
        // Make sure to assign error message and reason
        if (eventPayload.type != "unique") {
```
apiResponseProcessor.setMessage("Failed");
apiResponseProcessor.setReason("No reason needed");
return false;
}
},
type: 'AlarmAPIProcessor'
});

Additional REST operations

To create additional operations beyond the existing GET, PATCH, and POST operations, create additional scripted REST resources for the Alarm Management Open API. The logic of the new scripted REST resources should be consistent with the existing operations. Define functions for the new operations in TMFAlarmAPIUtil.

Field mapping

When creating or updating records, the API maps request body parameters to event record fields. When retrieving records, the API maps record fields to response object attributes. AlarmAPIProcessorOOB contains the following functions to map a PATCH or POST request body to a record in the Event [em_event] table.

• mapCreateAlarmObjectToEvent()
• mapClearAlarmObjectToEvent()
• mapPatchAlarmObjectToEvent()

AlarmAPIProcessorOOB contains the following functions to map an event GlideRecord to a JSON response object for GET, PATCH, or POST requests.

• modifyCreateEventResponse()
• modifyClearEventResponse()
• modifyPatchEventResponse()

Customize field mappings to add and retrieve data for additional Event [em_event] table fields or change the default field mappings. To work with mappings, create functions with identical names and parameters in AlarmAPIProcessor to override AlarmAPIProcessorOOB mapping functions. TMFAlarmAPIUtil uses these AlarmAPIProcessor functions to replace the default AlarmAPIProcessorOOB mapping functions.
In the following example, two `AlarmAPIProcessor` functions override the default functions in `AlarmAPIProcessorOOB` to change the Type field mapping and add a mapping for the Severity field.

```javascript
var AlarmAPIProcessor = Class.create();
AlarmAPIProcessor.prototype = Object.extendsObject(AlarmAPIProcessorOOB, {
    // Define overriding functions here
    mapCreateAlarmObjectToEvent: function(eventGr, eventObject) {
        // Override default mapping for the severity field
        eventGr.severity = "High";
    },

    modifyCreateEventResponse: function(eventGr, eventObject) {
        // Override default mapping for the type field
        eventGr.type = "Customized Event";
    },

    type: 'AlarmAPIProcessor'
});
```

**Alarm Management Open – POST – /sn_ind_tmf642/alarm_mgmt/alarm**

Creates an alarm as a new record in the Events (em_event) table and adds an ID to the Message key field.

The new alarm record this endpoint makes might result in creating an alert record based on the Event Management Alert management rules.

This endpoint writes the response body to the Additional Info field of the event record in the Events (em_event) table.

**URL format**

Default URL: `/api/sn_ind_tmf642/alarm_mgmt/alarm`

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<tr>
<td>alarmedObject.id</td>
<td>Required. Unique identifier of the alarming object. This value maps to a CI in the system.</td>
</tr>
<tr>
<td>alarmedObject.href</td>
<td>URL reference to get the details of the alarming object</td>
</tr>
<tr>
<td>alarmedObjectType</td>
<td>Type or class of object associated with the event.</td>
</tr>
<tr>
<td>alarmRaisedTime</td>
<td>Indicates the date and time at which the alarm occurs at its source.</td>
</tr>
</tbody>
</table>
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| alarmReportingTime        | Date and time at which the OSS reports its alarm. This value might differ from the `alarmRaisedTime` value. For example, if an element management system (EMS) maintains the alarm list:  
  - The `alarmRaisedTime` is the time of alarm detection by the network element (NE).  
  - The `alarmReportingTime` is the alarm report time of storage in the EMS alarm list.  
  Data type: String                                                                                                                                                                                                                                                                                                                                 |
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>400</td>
<td>Bad request.</td>
</tr>
</tbody>
</table>

Possible reasons:
- Invalid payload. Missing required alarm ID.
- Invalid payload. Required field missing:<field name>.
- Invalid payload. Missing required object.
- Event not created, failed.
- Unable to clear event.
- Unable to update event.
- The event doesn’t exist.

### Response body parameters (JSON or XML)

Alarm Management Open – POST – /sn_ind_tmf642/alarm_mgmt/alarm/{id}/clear

Clears a specified event alarm and closes any corresponding alert associated with the event in Event Management.

**URL format**

Default URL: /api/sn_ind_tmf642/alarm_mgmt/alarm/{id}/clear

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>id</td>
<td>Required. Unique ID in the Message key field of a record in the Events (em_events) table. Data type: String</td>
</tr>
</tbody>
</table>
Query parameters

<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>
## Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Successful. The request was successfully processed.</td>
</tr>
</tbody>
</table>
| 400         | Bad request. Possible reasons:  
  • Invalid payload. Missing required alarm ID.  
  • Invalid payload. Required field missing:<field name>.  
  • Invalid payload. Missing required object.  
  • Event not created, failed.  
  • Unable to clear event.  
  • Unable to update event.  
  • The event doesn’t exist. |

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| alarmClearedTime| Date and time at which the alarm clears at the source. This value is in the `Time of event` field of the record in the Events (em_events) table.  
  Data type: String |
| clearSystemId   | Name of the instance from which the `alarmCleared` operation was invoked.  
  Data type: String |
| clearUserId     | Unique ID of the who invoked the `alarmCleared` operation. This value is in the `Source` field of the record in the Events (em_events) table.  
  Data type: String |
<p>| href            | URL of the alarm.                                                                                                                            |</p>
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Unique ID in the Message key field of a record in the Events (em_events) table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

The following example shows how to clear an alarm.

```
curl
  "https://<instance>.service-now.com/api/sn_ind_tmf642/alarm_mgmt/alarm/6e116bb8db09201087b9a8394b961950_<external-alarm-id>/clear" \ 
  --request POST \ 
  --header "Accept:application/json" \ 
  --header "Content-Type:application/json" \ 
  --data "{
  "alarmClearedTime": "2017-08-15 06:04:15",
  "clearSystemId": "<source_instance_name>",
  "clearUserId": "SOURCE_SYSTEM_vManage_00000_000_00"
}"
  --user 'user':'password'
```

**Output:**

```
{
  "result": {
    "alarmClearedTime": "2017-08-15 06:04:15",
    "clearSystemId": "<source_instance_name>",
    "clearUserId": "SOURCE_SYSTEM_vManage_00000_000_00",
    "id": "6e116bb8db09201087b9a8394b961950_<external-alarm-id>"
  }
}
```

**Alarm Management Open – PATCH – /sn_ind_tmf642/alarm_mgmt/alarm/{id}**

Creates an event and update any associated alert record in Event Management.

This endpoint writes the response body to the Additional Info field of the event record in the Events (em_event) table.

**URL format**

Default URL: /api/sn_ind_tmf642/alarm_mgmt/alarm/{id}

</table>
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>that triggers the alarm.</td>
<td></td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td>serviceAffecting</td>
<td>Flag that indicates whether the alarm affects service.</td>
</tr>
<tr>
<td>Valid values:</td>
<td></td>
</tr>
<tr>
<td>• true: Alarm affects service performance or availability.</td>
<td></td>
</tr>
<tr>
<td>• false: Alarm does not affect service.</td>
<td></td>
</tr>
<tr>
<td>Default: false</td>
<td></td>
</tr>
<tr>
<td>specificProblem</td>
<td>Identifies the specific problem that triggers the alarm. Use with probableCause to qualify the alarm.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml.</td>
</tr>
<tr>
<td></td>
<td>Default: application/json</td>
</tr>
</tbody>
</table>
Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad request. Possible reasons:</td>
</tr>
<tr>
<td></td>
<td>• Invalid payload. Missing required alarm ID.</td>
</tr>
<tr>
<td></td>
<td>• Invalid payload. Required field missing:&lt;field name&gt;.</td>
</tr>
<tr>
<td></td>
<td>• Invalid payload. Missing required object.</td>
</tr>
<tr>
<td></td>
<td>• Event not created, failed.</td>
</tr>
<tr>
<td></td>
<td>• Unable to clear event.</td>
</tr>
<tr>
<td></td>
<td>• Unable to update event.</td>
</tr>
<tr>
<td></td>
<td>• The event doesn’t exist.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alarmChangedTime</td>
<td>Date and time the alarm changed in GMT on the alarm-owning system. This value is in GlideDateTime format and is in the Time of event field of a record in the Events (em_events) table. This value updates when changes to the alarm from the alarmed resource occur or a change from a client update triggers the alarm. This value is required in the response. Data type: String</td>
</tr>
<tr>
<td>href</td>
<td>URL reference to the alarm.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>id</td>
<td>Unique identifier of the alarm. Value determined by the system owning the alarm. Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

In the following example, the severity is reduced to MINOR.

```
curl  
  "https://<instance>.service-now.com/api/sn_ind_tmf642/alarm_mgmt/alarm/6e116bb8db09201087b9a8394b961950_<external-alarm-id>" \  
  --request PATCH \  
  --header "Accept:application/json" \  
  --header "Content-Type:application/json" \  
  --data "{

    "affectedService":[
      
      "id":"SD WAN Enterprise Solutions", 
    ]
  }  
```
Application Service API

Create, modify, and update application services using REST APIs. These APIs require that the user have the Application Service administrator [app_service_admin] role.

Application Service - GET /now/cmdb/app_service/{sys_id}/getContent

Retrieves a list of configuration items (CI) in an application service and the relationships between them. Only retrieves content for services that were manually created.

URL format

Default URL: /api/now/cmdb/app_service/{sys_id}/getContent

Supported request parameters

<table>
<thead>
<tr>
<th>Path parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
</tr>
<tr>
<td>sys_id</td>
</tr>
</tbody>
</table>

Output:

```
{
  "result": {
    "alarmChangedTime": "2017-08-15T07:04:15.666Z",
    "id": "6e116bb8db09201087b9a8394b961950_<external-alarm-id>"
  }
}
```
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| Mode   | Amount of relationship data to return. Valid values:  
  • Shallow: Return parent and child relationships between CIs within a service.  
  • Full: Return CI attributes and lookup information in addition to the data returned in shallow mode.  
  The values are not case-sensitive.  
  Data type: String |

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>

Application Service - GET /now/cmdb/csdm/app_service/find_service

Returns basic information about a specified application service and its associated business context.

⚠️  Note: This endpoint has been deprecated, use SG Services – POST – /sg_services/app_service/find instead.

URL format

Default URL: /api/now/cmdb/csdm/app_service/find_service
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| name | Required, if **number** is not passed in. Name of the service for which to return information. Located in the Application Service [cmdb_ci_service_auto] table.  
Data type: String |
| number | Required, if **name** is not passed in. Unique number that identifies the application service for which to return information. Located in the Application Service [cmdb_ci_service_auto] table.  
Data type: String |

### Request body parameters (XML or JSON)

</tbody>
</table>

Headers
The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
</tbody>
</table>

Request body

The API accepts these JSON elements in the request body. In addition, you can add any field from the Mapped Application Service [cmdb_ci_service_discovered] table to pass data to the application service record. For example, to add content to the Comments field, add "comments": "Passing data to the Comments field" to the JSON request.
Elements accepted in the request body

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of the application service you wish to create or update.</td>
</tr>
<tr>
<td>service_relations</td>
<td>Information about CIs and the hierarchy they form. All CIs form pairs with a parent CI and a child CI. The top-level CI, referred to as the entry point of an application service, does not have a parent CI.</td>
</tr>
<tr>
<td>parent</td>
<td>Sys_id of the CI whose outgoing connection joins this CI with the CI at the lower level in the map hierarchy.</td>
</tr>
<tr>
<td>child</td>
<td>Sys_id of the CI whose incoming connection joins this CI with the CI located of the higher level in the map hierarchy.</td>
</tr>
</tbody>
</table>

Response body
The API returns these JSON elements in the response body.

Elements returned in the response body

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL</td>
<td>URL of the standard table REST API for showing the sys_id of an application service record. This element appears only if the endpoint is successful. Data type: String</td>
</tr>
<tr>
<td>getContentUrl</td>
<td>REST API path for getting the application service content. This element appears only if the endpoint is successful. Data type: String</td>
</tr>
<tr>
<td>info</td>
<td>Number of CIs added to the application service. This element appears only if the endpoint is successful. Data type: String</td>
</tr>
<tr>
<td>error</td>
<td>Error message details. This element appears only if the endpoint fails. Data type: Object</td>
</tr>
<tr>
<td>message</td>
<td>Error message describing the nature of the failure.</td>
</tr>
</tbody>
</table>
Elements returned in the response body (continued)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This element appears only if the endpoint fails. Data type: String</td>
</tr>
<tr>
<td>status</td>
<td>States &quot;failure&quot; if the REST API fails. This element appears only if the endpoint fails. Data type: String</td>
</tr>
</tbody>
</table>

Example: Sample cURL request

```
curl "http://<instance.servicenow.com>/api/now/cmdb/app_service/create" \  
--request POST  
--header "Accept:application/json" \  
--header "Content-Type:application/json" \  
--data "{  
"name": "myTestAppService",  
"comments": "Passing data to the Comments field",  
"service_relations":  
[  
  {  
    "parent": "",  
    "child": "3a70f789c0a8ce010091b0ea635b982a"  
  },  
  {  
    "parent": "3a70f789c0a8ce010091b0ea635b982a",  
    "child": "b4fd7c8437201000deeabfc8bcbe5dc1"  
  },  
  {  
    "parent": "b4fd7c8437201000deeabfc8bcbe5dc1",  
    "child": "53fdbc8437201000deeabfc8bcbe5d10"  
  ]  
}  
"  
--user 'admin': 'admin'
```

```json
{
  "result": {
    "url": "http://<instance.servicenow.com>/api/now/table/cmdb_ci_service_discovered/b1cff89fc9e19300964fcb1ac3059a5",
    "getContentView": "http://<instance.servicenow.com>/api/now/cmdb/app_service/b1cff89fc9e19300964fcb1ac3059a5/getContent",
    "info": "3 CIs added to service"
  }
}```
Example: Sample Python request

```python
# Need to install requests package for python
import requests

# Set the request parameters
url = 'http://instance.service-now.com/api/now/cmdb/app_service/create

# Eg. User name="username", Password="password" for this code sample.
user = 'username'
pwd = 'password'

# Set proper headers
headers = {"Content-Type":"application/json","Accept":"application/json"}

# Do the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, data="{
  "name": "myTestAppService",
  "comments": "Passing data to the Comments field",
  "service_relations": [
    {"parent": "",
     "child": "3a70f789c0a8ce010091b0ea635b982a"},
    {"parent": "3a70f789c0a8ce010091b0ea635b982a",
     "child": "b4fd7c8437201000deabf88bcbe5dc1"},
    {"parent": "b4fd7c8437201000deabf88bcbe5dc1",
     "child": "53fdbc8437201000deabf88bcbe5d10"}
  ]
}
"

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```

```xml
<root>
  <result>
    <getContentUrl>/api/now/cmdb/app_service/b1cff89fc9e19300964fcbb1ac3059a5/getContent</getContentUrl>
  </result>
</root>
```
Application Service - POST /now/cmdb/csdm/app_service/register_service

Creates an application service record stub in the Application Service [cmdb_ci_service_auto] table and populates it with the passed in information.

Before storing the record, it validates the passed parameters and the uniqueness of the application service name. It also creates upstream relationships which provide business context to the service by associating the specified business applications, business service offerings, and technical service offerings to the service application. It does not create downstream relationships to infrastructure. To define downstream relationships you must call the Application Service - PUT /now/cmdb/csdm/app_service/{service_sys_id}/populate_service endpoint.

⚠️ Note: This endpoint has been deprecated, use SG Services – POST – /sg_services/app_service/register instead.

URL format

Default URL: /api/now/cmdb/csdm/app_service/register_service

Supported request parameters

</table>

Example: Sample cURL request

```bash
curl -X POST \
https://instance.servicenow.com/api/now/cmdb/csdm/app_service/register_service \
-H 'Accept: application/json' \
-H 'Content-Type: application/json' \
-u 'username': 'password' \
-d '{
  "basic_details": {
    "environment": "Test Lab 2",
    "name": "Test Lab 2",
    "version": "1.1.1"
  },
  "relationships": {
    "business_app": ["f07c7620db54101037740f95ca96199a"],
    "business_service_offering": ["069c7e20db54101037740f95ca9619bf"]
  }
}'
```

```json
{
  "result": {
    "service_sys_id": "80f21bbadb4d103d3a93c3e296199a",
    "number": "SNSVC0001018"
  }
}
```

Application Service - PUT /now/cmdb/csdm/app_service/{service_sys_id}/populate_service

Populates the specified application service with a specified set of downstream configuration items (CI).

Before calling this endpoint, you must call the POST /now/cmdb/csdm/app_service/register_service endpoint to create the application service.

⚠️ Note: This endpoint has been deprecated, use SG Services – POST – /sg_services/app_service/populate instead.

**URL format**

Default URL: /api/now/cmdb/csdm/app_service/{service_sys_id}/populate_service
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_sys_id</td>
<td>Sys_id of the application service to populate with the specified CIs. Located in the Application Service [cmdb_ci_service_auto] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>population_method</td>
<td>CIs to associate with the specified application service. The elements in the populate_method object depend on the type of information being populated; defined by the type parameter. Data type: Object</td>
</tr>
</tbody>
</table>

For **type** = cmdb_group_based

```json
{
  "population_method": {
    "group_id": "String",
    "type": "String"
  }
}
```

For **type** = discovery

**: Note:** To use this type you must activate the Service Mapping (com.snc.service-mapping) plugin.

```json
{
  "population_method": {
```

### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>population_method.attributes</td>
<td>List of attributes to associate with the CI, such as host, port, name, and URL. For additional information on entry points, see Entry point attributes.</td>
</tr>
<tr>
<td>population_method.attributes.name</td>
<td>Name of the attribute, such as host, port, name, and URL. Data type: String</td>
</tr>
<tr>
<td>population_method.attributes.value</td>
<td>Attribute value. Data type: String</td>
</tr>
</tbody>
</table>

For `type = tag_list`

위의 사용자 정의 `type`를 사용하기 위해서는 `Service Mapping (com.snc.service-mapping)` 플러그인을 활성화해야 합니다.

```json
{
    "population_method": {
        "tags": [Array],
        "type": "String"
    }
}
```

**Note:** To use this type you must activate the Service Mapping (com.snc.service-mapping) plugin.

**Note:** You must pass all required attributes.

```json
{
    "population_method": {
        "tags": [Array],
        "type": "String"
    }
}
```
### Request body parameters (XML or JSON) (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>population_method.entry_point</td>
<td>Required if <code>population_method.type = discovery</code>. Entry point into the application service. For additional information on entry points, see Entry point attributes and Create entry point types for Service Mapping. Data type: String</td>
</tr>
<tr>
<td>population_method.group_id</td>
<td>Required if <code>population_method.type = cmdb_group_based</code>. Sys_id of the group to associate with the CI. Located in the CMDB Group [cmdb_group] table. Data type: String</td>
</tr>
<tr>
<td>population_method.tags</td>
<td>List of tags to associate with the CI. This information is located in the Key Values [cmdb_key_value] table. Data type: Array</td>
</tr>
<tr>
<td></td>
<td><code>{  &quot;tags&quot;: {  &quot;tag&quot;: &quot;String&quot;,  &quot;value&quot;: &quot;String&quot; } }</code></td>
</tr>
<tr>
<td>population_method.tags.tag</td>
<td>Name of the tag. Data type: String</td>
</tr>
<tr>
<td>population_method.tags.value</td>
<td>Tag value. Data type: String</td>
</tr>
<tr>
<td>population_method.type</td>
<td>Required. Type of CI to populate. Valid values:  • cmdb_group_based  • discovery  • tag_list Data type: String</td>
</tr>
</tbody>
</table>
Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports <code>application/json</code>.</td>
</tr>
<tr>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or they do not have the app_service_admin role.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Describes an encountered error. Data type: Object</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>error.details</td>
<td>Additional information about the error. Data type: String</td>
</tr>
<tr>
<td>error.message</td>
<td>Message describing the error. Data type: String</td>
</tr>
</tbody>
</table>

**Example: Sample cURL request**

The following code example shows how to populate an application service when the CI type is `cmdb_group_based`.

```cURL
curl -X PUT \
https://instance.servicenow.com/api/now/cmdb/csdm/app_service/f809cb60db94101037740f95ca96190f/populate_service \
-H 'Accept: application/json' \
-H 'Content-Type: application/json' \
-u 'username':'password' \
-d '{
    "population_method": {
        "type": "cmdb_group_based",
        "group_id": "e809cf60db94101037640f95ca961932"
    }
}'
{
    "result": {}
}
```

The following code example shows how to populate a discovery application service.

```cURL
curl -X PUT \
https://instance.servicenow.com/api/now/cmdb/csdm/app_service/f809cb60db94101037740f95ca96190f/populate_service \
-H 'Accept: application/json' \
-H 'Content-Type: application/json' \
-u 'username':'password' \
```
Application Service - PUT /now/cmdb/csdm/app_service/{service_sys_id}/service_details

Updates the specified application service with the passed in basic information.

It also validates the uniqueness of the application service by checking the passed in information against the Identification and Reconciliation engine (IRE) rules defined on the application service class.

⚠️ Note: This endpoint has been deprecated, use SG Services – POST – /sg_services/app_service/update instead.

URL format

Default URL: /api/now/cmdb/csdm/app_service/{service_sys_id}/service_details
### Supported request parameters

#### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or they do not have the app_service_admin role.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Describes an encountered error.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>
<td>&quot;error&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;details&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;message&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>error.details</td>
<td>Additional information about the error.</td>
</tr>
<tr>
<td>error.message</td>
<td>Message describing the error.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Example: Sample cURL request**

```bash
curl -X PUT \
https://instance.servicenow.com/api/now/cmdb/csdm/app_service/f809cb60db941037740f95ca96190f/service_details \
-H 'Accept: application/json' \
-H 'Content-Type: application/json' \
-u 'username':'password' \
-d '{
  "basic_details": {
    "environment": "Test Lab 2"
  },
  "relationships": {
    "business_app" :["f07c7620db54101037740f95ca96199a"]
  }
}'

{
  "result": {}
}
```

**Attachment API**

The Attachment API allows you to upload and query file attachments.

You can upload or retrieve a single file with each request.

The Attachment API respects any system limitations on uploaded files, such as maximum file size and allowed attachment types. You can control these settings using the properties `com.glide.attachment.max_size`, 1024MB by default, and `glide.attachment.extensions`.

ℹ️ **Note:** The Attachment API accepts all Content-Type values (*/*). Specify the file content type when uploading an attachment. The content type is stored with file metadata allowing other tools to correctly identify and parse the file.

The following video provides more information on the Attachment API:

Web Services Part 5 | How to Make REST Attachment API Requests

© 2021 ServiceNow, Inc. All rights reserved.
ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
Attachment API role requirements

To create attachments, the user record used to authenticate the HTTP request with ServiceNow must have any roles required to create Attachment [sys_attachment] records. It must also have any roles required to read and write records on the target table, such as the itil role to add attachments to incident records.

By default there is no single role allowing a user to add attachments. You can create a role to explicitly allow adding attachments, then assign this role to the user account being used to make the request.

Attachment - DELETE /now/attachment/{sys_id}

This method deletes the attachment with a specific sys_id value.

URL format

Versioned URL: /api/now/v1/attachment/{sys_id}
Default URL: /api/now/attachment/{sys_id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>Sys_id value of the attachment to delete. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Headers
The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes
The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>204</td>
<td>Indicates the request ran successfully.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Example: cURL request

curl "https://instance.servicenow.com/api/now/attachment/615ea769c0a80166001cf5f2367302f5"
  --request DELETE \
  --user 'username':'password'

Example: Python request

# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/attachment/615ea769c0a80166001cf5f2367302f5'
user = 'username'
pwd = 'password'

# Make the HTTP request
response = requests.delete(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',response.json())
    exit()

None

Attachment - GET /now/attachment

Returns the metadata for multiple attachments.

URL format

Versioned URL: api/now/v1/attachment

Default URL: api/now/attachment
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_limit</td>
<td>Limit to be applied on pagination.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Unusually large <code>sysparm_limit</code> values can impact system performance.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Default: 10000</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Number of records to exclude from the query. Use this parameter to get more records than specified in <code>sysparm_limit</code>. For example, if <code>sysparm_limit</code> is set to 500, but there are additional records you want to query, you can specify a <code>sysparm_offset</code> value of 500 to get the second set of records.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Default: 0</td>
</tr>
<tr>
<td>sysparm_query</td>
<td>Encoded query. Queries for the <code>Attachment</code> API are relative to the <code>Attachments [sys_attachment]</code> table.</td>
</tr>
<tr>
<td></td>
<td>For example: <code>(sysparm_query=file_name=attachment.doc)</code></td>
</tr>
<tr>
<td></td>
<td>The encoded query provides support for <code>ORDERBY</code>. To sort responses based on certain fields, use the <code>ORDERBY</code> and <code>ORDERBYDESC</code> clauses in <code>sysparm_query</code>. For example, <code>sysparm_query=ORDERBYfile_name^ORDERBYDESCtable_Name</code> orders the results in ascending order by name first, then in descending order by table name.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

Attachment - GET /now/attachment/{sys_id}/file

Returns the binary file attachment with a specific sys_id value.

URL format

Versioned URL: /api/now/v1/attachment/{sys_id}/file

Default URL: /api/now/attachment/{sys_id}/file

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id</td>
<td>Sys_id of the attachment record from which to return binary data.</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>

## Example: cURL request

```bash
curl "https://instance.servicenow.com/api/now/attachment/615ea769c0a80166001cf5f2367302f5/file" \
  --request GET \
  --header "Accept:*/*" \
  --user "username":"password"
```

Binary response not shown.

## Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/attachment/615ea769c0a80166001cf5f2367302f5/file'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept': '*/*'}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

Binary response not shown.
```
Attachment - GET /now/attachment/{sys_id}
Returns the metadata for the attachment file with a specific sys_id value.

Attachment - POST /now/attachment/file

Uploads a specified binary file as an attachment to a specified record.

⚠️ Note: The file to attach must be specified after the last parameter in the passed-in request parameter list.

**URL format**

Versioned URL: /api/now/v1/attachment/file
Default URL: /api/now/attachment/file
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encryption_context</td>
<td>Sys_id of an encryption context record. Specify this parameter to allow only users with the specified encryption context to access the attachment. For additional information on encryption context records, see Encryption Support.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Default: Attached file is not encrypted with any encryption context.</td>
</tr>
<tr>
<td>file_name</td>
<td>Required. Name to give the attachment.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>table_name</td>
<td>Required. Name of the table to attach the file to.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>table_sys_id</td>
<td>Required. Sys_id of the record in the table specified in <code>table_name</code> that you want to attach the file to.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;String&gt;</td>
<td>Path to the binary file to attach to the specified record.</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Content type of the file to attach, such as image/jpeg or /*. This header is mandatory to post file attachments.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location</td>
<td>URL of the new attachment.</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Indicates the query ran successfully.</td>
</tr>
<tr>
<td>400</td>
<td>Indicates that one or more mandatory parameters were missing from the request.</td>
</tr>
<tr>
<td>404</td>
<td>Indicates the record specified by the table_name and table_sys_id parameters does not exist or is not accessible to the current user.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>

 |

result.average_image_color | If the attachment is an image, the sum of all colors.  
Data type: String  
Unit: RGB or number of pixels.  
result.compressed | Flag that indicates whether the attachment file has been compressed.  
Valid values:  
• true: File has been compressed.  
• false: File has not been compressed.  
Data type: String  
result.content_type | Content-type of the associated attachment file, such as image or jpeg or application/x-shockwave-flash.  
Data type: String
<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| result.created_by_name      | Full name of entity that originally created the attachment file.  
Data type: String                                                                 |
| result.download_link        | Download URL of the attachment on the ServiceNow instance.  
Data type: String                                                                 |
| result.file_name            | File name of the attachment.  
Data type: String                                                                 |
| result.image_height         | If an image file, the height of the image.  
Data type: String  
Unit: Pixels                                                              |
| result.image_width          | If an image file, the width of the image.  
Data type: String  
Unit: Pixels                                                              |
| result.size_bytes           | Size of the attachment.  
Data type: String  
Unit: Bytes                                                                |
| result.size_compressed      | Size of the compressed attachment file. If the file is not compressed, empty.  
Data type: String  
Unit: Bytes                                                                |
| result.sys_created_by       | Entity that originally created the attachment file.  
Data type: String                                                              |
| result.sys_created_on       | Date and time that the attachment file was initially saved to the instance.  
Data type: String                                                              |
| result.sys_id               | Sys_id of the attachment file.  
Data type: String                                                              |
<p>| result.sys_mod_count        | Number of times the attachment file has been modified (uploaded to the instance).                                                          |</p>
<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result.sys_tags</td>
<td>Any system tags associated with the attachment file.</td>
</tr>
<tr>
<td>result.sys_updated_by</td>
<td>Entity that last updated the attachment file.</td>
</tr>
<tr>
<td>result.sys_updated_on</td>
<td>Date and time that the attachment file was last updated.</td>
</tr>
<tr>
<td>result.table_name</td>
<td>Name of the table to which the attachment is associated.</td>
</tr>
<tr>
<td>result.table_sys_id</td>
<td>Sys_id of the table associated with the attachment.</td>
</tr>
<tr>
<td>result.updated_by_name</td>
<td>Full name of entity that last updated the attachment file.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```
curl 
  "https://instance.servicenow.com/api/now/attachment/file?table_name=incident&table_sys_id=
d71f7935c0a8016700802b64c67c11c6&file_name=Issue_screenshot" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type: image/jpeg" \
  --user "username":"password" \
  --data-binary "@ location of the file on file system"
```

```json
{
  "result": {
    "table_sys_id": "d71f7935c0a8016700802b64c67c11c6",
    "size_bytes": "36597",
    "download_link": 
  "https://instance.servicenow.com/api/now/attachment/6ea10fe64f411200adf9f8e18110c739/file"
  }
}
```
Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url =
'https://instance.servicenow.com/api/now/attachment/file?table_name=incident&table_sys_id=d71f7935c0a8016700802b64c67c11c66&file_name=Issue_screenshot.jpg'

# Specify the file To send. When specifying files to send make sure you specify the path to the file, in
# this example the file was located in the same directory as the python script being executed.
data = open('Issue_screenshot.jpg', 'rb').read()

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = ("Content-Type":"image/jpeg","Accept":"application/json")

# Make the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, data=data)
```
# Check for HTTP codes other than 201
if response.status_code != 201:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

        "image_height": "",
        "sys_created_on": "2016-01-22 15:14:07",
        "file_name": "Issue_screenshot.jpg",
        "sys_created_by": "admin",
        "compressed": "true",
        "average_image_color": "",
        "sys_updated_by": "admin",
        "sys_tags": "",
        "table_name": "incident",
        "image_width": "",
        "sys_mod_count": "0",
        "content_type": "image/jpeg",
        "size_compressed": "25130"
    }
}

Attachment - POST /now/attachment/upload

Uploads a multipart file attachment.

The multipart POST method does not accept any parameters. You must specify the table name and record sys_id values within the form body. See the cURL example for a sample of a multipart/form-data request.
Important: When using multipart POST, ensure that the file content is contained in the final part of the message only. Earlier parts should contain only metadata such as table name and record sys_id.

**URL format**

Versioned URL: /api/now/v1/attachment/upload

Default URL: /api/now/attachment/upload

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Name</strong></td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Query parameters</th>
</tr>
</thead>
<tbody>

<td><strong>Name</strong></td>
</tr>
<tr>
<td>None</td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

| **Name** | **Description** |
| None | |

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Content type of the request. Set this value to multipart/form-data when using the multipart POST method.</td>
</tr>
</tbody>
</table>
Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Location</td>
<td>URL of the new attachment.</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>Indicates the query ran successfully.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Metadata of the requested attachment.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
</tbody>
</table>

</tbody>
</table>

**POST multipart mandatory values**

When sending a multipart POST request to upload a file attachment, include attachment data in the message body, not in the URL parameters. You must specify these values in the message body:

**Mandatory values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>Content-Type of the file, included in the message body for multipart uploads.</td>
</tr>
<tr>
<td></td>
<td><em>Note:</em> The Content-Type must be defined within the file portion of the POST message, not within the form data. See the sample POST multipart message for an example of a multipart message.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>table_name</td>
<td>Name of the table to which you want to attach the file.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>table_sys_id</td>
<td>Sys_id of the record on the specified table to which you want to attach the file.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```bash
curl "https://instance.servicenow.com/api/now/attachment/upload" \
--request POST \ 
--header "Accept:application/json"\n```
Example: Python request

```python
# This example uses the Python Requests Library and you will need to install requests package for python
# Documentation can be found at http://docs.python-requests.org/en/master/user/quickstart/
import requests
import pprint
import json

# Specify the Endpoint URL replacing instance with your ServiceNow Instance Name
url = 'https://instance.service-now.com/api/now/attachment/upload'
```
# Specify Parameters for File Being Uploaded, the table_name and table_sys_id should be replaced with values that make sense for your use case
payload = {'table_name': 'incident', 'table_sys_id': '81f8915b0b6ba20028927416bf961971'}

# Specify Files To Send and Content Type. When specifying files to send make sure you specify the path to the file, in this example the file was located in the same directory as the python script being executed.
# it is important to specify the correct file type
files = {'file': ('issue_screenshot.JPG', open('issue_screenshot.JPG', 'rb'), 'image/jpg', {'Expires': '0'})}

# Eg. User name="username", Password="password" for this code sample. This will be sent across as basic authentication
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept': '*/*'}

# Send the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, files=files, data=payload)

# Check for HTTP codes other than 201
if response.status_code != 201:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Print Response Details
print 'Response Status Code:', response.status_code

print ''
print('Response Payload:
print json.dumps(response.json(), indent=4)

Response Status Code: 201

Response Payload:
{
  "result": {
    "sys_tags": "",
    "sys_updated_by": "admin",
  }
AWA Agent API

Use the AWA (Advanced Work Assignment) Agent API to get or set agent presence and channel availability.

The AWA Agent API is provided within the sn_awa namespace.

It requires the Advanced Work Assignment (com.glide.awa) plugin and the awa_integration_user role.

**AWA Agent - GET /now/awa/agents/{user_id}**

Returns the current agent presence state and channel availability.

**URL format**

Versioned URL: /api/now/{api_version}/awa/agents/{user_id}

Default URL: /api/now/awa/agents/{user_id}
## Supported request parameters

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, <code>v1</code> or <code>v2</code>. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>user_id</td>
<td>Sys_id of the agent. Located in the User <code>[sys_user]</code> table. Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>presence.channels.flag</td>
<td>Indicates whether the channel is available. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Channel is available.</td>
</tr>
<tr>
<td></td>
<td>• false: Channel is not available.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>presence.channels.sys_id</td>
<td>Channel sys_id. Located in the Service Channels <code>[awa_service_channel_list]</code> table. Data type: String</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: <strong>application/json</strong> or <strong>application/xml</strong>. Default: <strong>application/json</strong></td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: <strong>application/json</strong> or <strong>application/xml</strong>. Default: <strong>application/json</strong></td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>
### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>presence</td>
<td>Information about an agent’s current presence state and channel. Data type: Object</td>
</tr>
<tr>
<td></td>
<td>{&quot;presence&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;available&quot;: Boolean,</td>
</tr>
<tr>
<td></td>
<td>&quot;channels&quot;: [Array],</td>
</tr>
<tr>
<td></td>
<td>&quot;name&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;sys_id&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>presence.available</td>
<td>Flag that indicates whether the agent is available. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Agent is available.</td>
</tr>
<tr>
<td></td>
<td>• false: Agent is not available.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>presence.channels</td>
<td>List of objects that describe the available channels of communication with the agent. Data type: Array</td>
</tr>
<tr>
<td></td>
<td>{&quot;channels&quot;: [</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;available&quot;: Boolean,</td>
</tr>
<tr>
<td></td>
<td>&quot;name&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;sys_id&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>presence.channels.available</td>
<td>Flag that indicates whether the channel is available. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: Channel is available.</td>
</tr>
<tr>
<td></td>
<td>• false: Channel is not available.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td>presence.channels.name</td>
<td>Channel name, such as Chat or Phone.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML) (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>presence.channels.sys_id</td>
<td>Channel sys_id. Located in the Service Channels [awa_service_channel_list] table. Data type: String</td>
</tr>
<tr>
<td>presence.name</td>
<td>Name of the agent’s presence state. Possible values: • Available • Unavailable Data type: String</td>
</tr>
<tr>
<td>presence.restrict_update</td>
<td>Flag that indicates whether the user can restrict updates. Possible values: • true: User can restrict updates. • false: User cannot restrict updates. Data type: Boolean</td>
</tr>
<tr>
<td>sys_id</td>
<td>Agent sys_id. Data type: String</td>
</tr>
</tbody>
</table>

### Example: Sample cURL request

```bash
curl -X GET \
https://instance.servicenow.com/api/now/awa/agents/46d44a23a9fe19810012d100c8a80666 \
-H 'Accept: application/json' \
-H 'Content-Type: application/json' \
-u 'username': 'password'\
{
    "result": {
        "presence": {
            "name": "Available",
            "sys_id": "0b10223c57a313005b4a65ef94f970",
```
Example: Sample Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/awa/agents/46d44a23a9fe19810012d100cca80666'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {"Content-Type": "application/json", "Accept": "application/json"}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers, data="{"presence": 
{"sys_id": "0b10223c57a313005baaaa65ef94f970", 
"channels": [{"sys_id": "0bbdedbb3b892300a2bac9bb34efc445", "available": 
true }]
}

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',response.content)
    exit()

# Decode the JSON response into a dictionary and use the data
print(response.content)
```
AWA Agent - PUT /now/awa/agents/{user_id}
Sets the state of a specified agent’s presence and, if provided, sets the agent’s channel availability for that state.

**URL format**

Versioned URL: /api/now/{api_version}/awa/agents/{user_id}
Default URL: /api/now/awa/agents/{user_id}

**Supported request parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>user_id</td>
<td>Sys_id of the agent. Located in the User [sys_user] table.</td>
</tr>
</tbody>
</table>
Query parameters

<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>presence</td>
<td>Information about an agent's current presence state and channel.</td>
</tr>
</tbody>
</table>
### Response body parameters (JSON or XML) (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data type:</strong></td>
<td>Object</td>
</tr>
</tbody>
</table>

```json
"presence": {
    "available": Boolean,
    "channels": [Array],
    "name": "String",
    "sys_id": "String"
}
```

**presence.available**  
Flag that indicates whether the agent is available.  
Possible values:  
- true: Agent is available.  
- false: Agent is not available.  

**Data type:** Boolean

**presence.channels**  
List of objects that describe the available channels of communication with the agent.  

**Data type:** Array

```json
"channels": [
    {
        "available": Boolean,
        "name": "String",
        "sys_id": "String"
    }
]
```

**presence.channels.available**  
Flag that indicates whether the channel is available.  
Possible values:  
- true: Channel is available.  
- false: Channel is not available.  

**Data type:** Boolean

**presence.channels.name**  
Channel name, such as Chat or Phone.  

**Data type:** String

**presence.channels.sys_id**  
Channel sys_id. Located in the Service Channels [awa_service_channel_list] table.
### Response body parameters (JSON or XML) (continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>presence.name</td>
<td>Name of the agent's presence state. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• Available</td>
</tr>
<tr>
<td></td>
<td>• Unavailable</td>
</tr>
<tr>
<td>presence.restrict_update</td>
<td>Flag that indicates whether the user can restrict updates. Possible values:</td>
</tr>
<tr>
<td></td>
<td>• true: User can restrict updates.</td>
</tr>
<tr>
<td></td>
<td>• false: User cannot restrict updates.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Agent sys_id.</td>
</tr>
</tbody>
</table>

```
curl -X PUT \
  https://instance.servicenow.com/api/now/awa/agents/46d44a23a9fe19810012d100cca80666 \
  -H 'Accept: application/json' \
  -H 'Content-Type: application/json' \
  -u 'username':'password'\n  -d '{"presence": {\n    "sys_id": "0b10223c57a313005baaa65ef94f970",\n    "channels": [{\n      "sys_id": "0bbdedbb3b892300a2bac9bb34efc445",\n      "available": true
    }]
  }}
```
Example: Sample Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/awa/agents/46d44a23a9fe19810012d100cca80666'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {"Content-Type":"application/json","Accept":"application/json"}

# Make the HTTP request
response = requests.put(url, auth=(user, pwd), headers=headers, data='{"presence":{
  \"sys_id\": "0b10223c57a313005baaaa65ef94f970",
  \"channels\": [{
    \"sys_id\": "0b10223c57a313005baaaa65ef94f970",
    \"available\": true
  }],
  \"available\": true
}}')

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the JSON response into a dictionary and use the data
print(response.content)
```

AWA Assignment API

Use the AWA Assignment API to manually assign work items to agents.

This API requires the Advanced Work Assignment (com.glide.awa) plugin and awa_manager role.

A work item is a single piece of work handled by an AWA agent from start to finish. For example, one chat or one case is an object that can be routed and assigned to agents. For more information, refer to Advanced Work Assignment.

**AWA Manual Assign – POST /awa/workitems/{work_item_sys_id}/assignments**

Assigns an available work item to an available Advanced Work Assignment agent.

The primary use case for this endpoint is to enable external routing systems to route work items. If Advanced Work Assignment is configured to use external routing, work items in the queue are assigned using external routing and not AWA. The work item task can be assigned by calling this endpoint. For information, refer to Use external routing.

**URL format**

Versioned URL: /now/{api_version}/awa/workitems/{sys_id}/assignments

Default URL: /now/awa/workitems/{sys_id}/assignments
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>work_item_sys_id</td>
<td>Sys_id of the work item to assign to an available agent. Located in the Work Items [awa_work_item] table. The work item must be unassigned and in the Pending Accept or Queued state. For information, refer to Check unassigned task work items. Type: String</td>
</tr>
</tbody>
</table>

Query parameters

</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent_sys_id</td>
<td>Required. Sys_id of the available agent to receive the work item. Agents are users with the awa_agent role in the User [sys_user] table. For information on how to determine if an agent is available, refer to Agent Inbox controls. Type: String</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.
Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>409</td>
<td>Conflict. The request could not pass due to an error with the provided work item or agent sys_id.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>
# Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>Flag that indicates whether the manual work item assignment is successful.</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Work item assignment successful.</td>
</tr>
<tr>
<td></td>
<td>• false: Work item assignment unsuccessful.</td>
</tr>
<tr>
<td></td>
<td>Data type: Boolean</td>
</tr>
<tr>
<td></td>
<td>Default: True</td>
</tr>
<tr>
<td>message</td>
<td>Response message acknowledging successful assignment or exception. Exceptions:</td>
</tr>
<tr>
<td></td>
<td>• &quot;Work item can not be assigned&quot; – Work item provided cannot be assigned because it is in <strong>Accepted</strong> or <strong>Canceled</strong> state. Refer to Check work items and AWA events.</td>
</tr>
<tr>
<td></td>
<td>• &quot;&lt;agent_sys_id&gt; is not a valid agent&quot; – Agent does not have the awa_agent role.</td>
</tr>
<tr>
<td></td>
<td>• &quot;&lt;work_item_sys_id&gt; is not a valid work item&quot; – Provided work item sys_id does not exist.</td>
</tr>
<tr>
<td></td>
<td>• &quot;Work Item is already assigned to &lt;work_item_sys_id&gt;&quot; – Provided work item is assigned to another agent.</td>
</tr>
<tr>
<td></td>
<td>• &quot;Agent is not available&quot; – Agent is not in the <strong>Available</strong> state in AWA. Refer to Agent inbox controls.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

## Example: cURL request

The following example shows how to assign a work item to an available AWA agent.

```bash
curl "https://instance.servicenow.com/api/now/awa/workitems/<work_item_sys_id>/assignments" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json"
```
The result shows that the task has been successfully assigned to the agent. You can verify results in the Assigned to field of the Work Items [awa_work_item] table.

```json
{
  "result": {
    "success": true,
    "message": "Manual assignment successfully requested"
  }
}
```

**AWA Routing API**

Use the AWA (Advanced Work Assignment) API to route a document to a queue.

Requires the Advanced Work Assignment plugin (com.glide.awa) and awa_integration_user role.

**AWA Routing - POST /now/awa/queues/{queue_sys_id}/work_item**

If an active work item exists, routes a document to a queue. If an active work item does not exist for the specified document, creates a work item and set its fields accordingly.

**URL format**

Versioned URL: /api/now/{api_version}/awa/queues/{queue_sys_id}/work_item

Default URL: /api/now/awa/queues/{queue_sys_id}/work_item

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>

<tr>
<td>sys_id</td>
<td>Sys_id of the work item assigned to the queue. Data type: String</td>
</tr>
</tbody>
</table>

Example: Sample cURL request

```
curl -X POST  
https://instance.servicenow.com/api/now/awa/queues/339eed3f3b892300a2bac9bb34efc4c3/work_item  
-H 'Content-Type: application/json'  
-H 'Accept: application/json'  
-u 'username':'password'  
-d '{
```
Example: Sample Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/now/awa/queues/339eed3f3b892300a2bac9bb34efc4c3/work_item'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {"Content-Type":"application/json","Accept":"application/json"}

# Make the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers,
                         data="{"document_sys_id":"9c573169c611228700193229fff72400",
                         "document_table": "incident"}
                         ")

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.content)
    exit()

# Decode the JSON response into a dictionary and use the data
print(response.content)
```
Batch API

The Batch API lets you send a single request containing multiple REST API calls, and returns a stream of response payloads.

This REST API enables integrators to:

• Decrease the amount of time required to send API requests by batching them together, and reduce overhead by narrowing authentication, session setup, and round-trip traffic to a single step.
• Create more efficient code for client-side integrations.
• Mix batch item formats and include them in single batch request. For example, one batch can include a Bases64-encoded request in XML format to send to one endpoint and a Base64 encoded request in JSON format to send to a different endpoint.
• Receive a stream of response payloads in return.
• Apply existing ACLs to each API call in the batch.

You can include any API available on the instance in a Batch API call. For performance reasons, avoid including long-running requests and requests that retrieve large amounts of data.

Size and processing limits

Payloads adhere to these size limits:

• Each item in the request: 5 MB. You can change this default by updating the glide.rest.batch.max.inputSize system property. Maximum value: 10 MB.
• Each item in the response: 10 MB. You can change this default by updating the glide.rest.batch.max.outputSize system property or adding the X-BATCHREQUEST-MAX-OUTPUT-SIZE header to your request. The X-BATCHREQUEST-MAX-OUTPUT-SIZE header value cannot exceed the value of the system property.
**Note:** If a request runs longer than 30 seconds, the REST Batch API request timeout transaction quota rule ends the transaction. Increasing the value of this transaction quota rule may result in performance issues.

When a batch request reaches a size or processing limit, the system cancels the transaction and returns unprocessed requests in the **unserviced** JSON array in the response.

**Batch - POST /now/batch**
Sends multiple REST API requests in a single call.

You can include any API available on the instance in a Batch API call. For performance reasons, avoid including long-running requests and requests that retrieve large amounts of data.

**URL format**
Versioned URL: /api/now/{api_version}/batch

**Supported request parameters**

**Path parameters**

}
Case API

The Case REST API enables you to retrieve and update Customer Service Management (CSM) case records.

© 2021 ServiceNow, Inc. All rights reserved.

ServiceNow, the ServiceNow logo, Now, and other ServiceNow marks are trademarks and/or registered trademarks of ServiceNow, Inc., in the United States and/or other countries. Other company names, product names, and logos may be trademarks of the respective companies with which they are associated.
In addition, you can generate new social media profile records when creating a case.

The Case API requires the Customer Service plugin (com.sn_customerservice) and is provided within the sn_customerservice namespace.

Users require the csm_ws_integration role for full API access. External users with the sn_customerservice.customer or sn_customerservice.consumer roles can access the case API endpoints.

**Case - GET /sn_customerservice/case/{id}/activities**

Retrieves the activity stream for a specified Customer Service Management (CSM) case.

Use this endpoint to retrieve all entries from the activity stream for a specified record from the Case [sn_customerservice_case] table.

To use this endpoint, users must have the csm_ws_integration, sn_customerservice.customer, or sn_customerservice.consumer role.

**Note:** You can reference all sysparm query parameters using either their full name or their shortened name (without the `sysparm_` prefix). For example, for `sysparm_limit` you can also use `limit`.

**URL format**

Versioned URL: `/api/sn_customerservice/{api_version}/case/{id}/activities`

Default URL: `/api/sn_customerservice/case/{id}/activities`

**Supported request parameters**

<table>
<thead>
<tr>
<th>Path parameters</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td></td>
<td>id</td>
<td>Sys_id or case number of the case to retrieve. Located in the Case [sn_customerservice_case] table. Results will be unpredictable if a specified case number is shared by two or more cases. Data type: String</td>
</tr>
</tbody>
</table>
### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| `sysparm_activity_type` | Filters the type of activities to return from the activity stream. The `entries.element` parameter contains the activity type for each activity. For example:  
  • `sysparm_activity_type=attachment`  
  • `sysparm_activity_type=work_notes`  
  • `sysparm_activity_type=attachment,work_notes`  
  • `sysparm_activity_type=attachment,work_notes,comments`  
  Data type: String  
  Default: Returns all types of activity. |
| `sysparm_limit`         | Maximum number of records to return. Unusually large `sysparm_limit` values can impact system performance. For requests that exceed this number of records, use the `sysparm_offset` parameter to paginate record retrieval.  
  Data type: Number |
| `sysparm_offset`        | Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks.  
  For example, the first time you call this endpoint, `sysparm_offset` is set to "0". To simply page through all available records, use `sysparm_offset=sysparm_offset +sysparm_limit`, until you reach the end of all records.  
  Data type: Number  
  Default: 0 |
Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Link</td>
<td>REST response data can be split into multiple result sets. Where applicable, the response header contains different links for the first set, previous set, next set, and the last set of records. For example:</td>
</tr>
<tr>
<td></td>
<td>https://&lt;instance name&gt;.service-now.com/api/now/table/cmdb_ci?sysparm_offset=40&amp;sysparm_limit=10000&gt;;rel=&quot;next&quot;,</td>
</tr>
<tr>
<td></td>
<td>https://&lt;instance name&gt;.service-now.com/api/now/table/cmdb_ci?sysparm_offset=40&amp;sysparm_limit=10000&gt;;rel=&quot;prev&quot;,</td>
</tr>
<tr>
<td></td>
<td>https://&lt;instance name&gt;.service-now.com/api/now/table/cmdb_ci?sysparm_offset=0&amp;sysparm_limit=10000&gt;;rel=&quot;first&quot;,</td>
</tr>
<tr>
<td></td>
<td>https://&lt;instance name&gt;.service-now.com/api/now/table/cmdb_ci?sysparm_offset=2780&amp;sysparm_limit=10000&gt;;rel=&quot;last&quot;</td>
</tr>
<tr>
<td>X-Total-Count</td>
<td>Response header showing the total number of records matching the request when the sysparm_limit of sysparm_offset query parameters are specified.</td>
</tr>
</tbody>
</table>
Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The requested item was not found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>display_value</td>
<td>Case number for the CSM case. Data type: String</td>

</tbody>
</table>
Example: cURL request
Retrieves the complete activity stream for a CSM case by sys_id.

```bash
curl --request GET
'https://instance.servicenow.com/api/sn_customerservice/case/f352dc9387632300d6b0a7da0acb0b60/activities' \
--request GET \
--header 'Accept: application/json' \
--user 'username': 'password'
```

The response shows a single activity stream entry for the specified case, an **Additional comments** journal entry submitted by the agent.

```json
{
  "result": {
    "display_value": "CS0001401",
    "sys_id": "f352dc9387632300d6b0a7da0acb0b60",
    "short_description": "Laptop is not working properly",
    "number": "CS0001401",
    "entries": [
      {
        "sys_created_on_adjusted": "2020-05-04 14:15:44",
        "sys_id": "600b6e4adb241010d045232d1396196a",
        "login_name": "John Jason",
        "user_sys_id": "da419c1fc312310015519f2974d3ae15",
        "initials": "JJ",
        "sys_created_on": "2020-05-04 21:15:44",
        "contains_code": "false",
        "field_label": "Additional comments",
        "name": "John Jason",
        "value": "Hi, Alex. Can you please send me a photo of the label on your laptop so we can send you the correct replacement?",
        "element": "comments"
      }
    ],
    "user_sys_id": "b1e0989f87232300d6b0a7da0acb0beb",
    "user_full_name": "Mark Johnson",
    "user_login": "admin",
    "label": "Case",
    "table": "sn_customerservice_case",
    "journal_fields": [
      {
        "can_read": true,
        "color": "transparent",
        "can_write": true,
```
Example: Python request
Retrieve the fourth and fifth activity stream entries for a CSM case by case number.

```python
# Install requests package for python
import requests

# Set the API endpoint URL for the request
url = "https://instance.servicenow.com/api/sn_customerservice/case/CS0030245/activities"

# Set the user credentials
user = "username"
pwd = "password"

# Set the query parameters
params = {
    "sysparm_offset": 3,
    "sysparm_limit": 2
}

# Set the HTTP headers
headers = {"Accept": "application/xml"}

# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), params=params, headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    # Code for handling error response
```
The XML response includes the two requested activity stream entries from the CSM case, including an image attachment and an email message attachment.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <display_value>CS0030245</display_value>
    <short_description>Urgent issue, can't send email</short_description>
    <label>Case</label>
    <sys_id>cf866683c303310fb12d9f2974d3ae1f</sys_id>
    <number>CS0030245</number>
    <sys_created_on.adjusted>2020-05-04 17:00:00</sys_created_on.adjusted>
    <entries>
      <sys_created_on.adjusted>2020-05-04 12:38:09</sys_created_on.adjusted>
      <sys_id>8a526e421be010102ebcd56ec4bcb89</sys_id>
      <login_name>Alex Linde</login_name>
      <user.sys_id>a.linde</user.sys_id>
      <attachment>
        <path>8a526e421be010102ebcd56ec4bcb89.iix</path>
        <sys_id>8a526e421be010102ebcd56ec4bcb89</sys_id>
        <thumbnail_path>8a526e421be010102ebcd56ec4bcb89.iix?t=small</thumbnail_path>
        <size_bytes>8298</size_bytes>
        <image_height>183</image_height>
        <content_type>image/jpeg</content_type>
        <size>8.1 KB</size>
        <file_name>screenshot.jpg</file_name>
        <image_path>8a526e421be010102ebcd56ec4bcb89.iix?t=large</image_path>
        <state>available</state>

      <name>user@customer</name>
    </entries>
  </result>
</response>
```
Case - GET /sn_customerservice/case/field_values/{field_name}

Retrieves the list of possible field values for a choice or reference field in the Case [sn_customerservice_case] table.

To use this endpoint, users must have the csm_ws_integration, sn_customerservice.customer, or sn_customerservice.consumer role.

Use this endpoint to populate field value lists in case creation forms.

When you request values for a reference field, any reference qualifiers defined for the requested field in the Dictionary Entry [sys_dictionary] table are applied. For more information on reference qualifiers, see Reference qualifiers.

You can use the sysparm_ref_qual_input query parameter to specify field values to use when evaluating JavaScript reference qualifiers. For an example, see the query parameter listing below.

When you request values for a choice field that is dependent on another field, you can use the sysparm_dependent_value query parameter to specify a value for the dependency parent field and restrict the returned field values accordingly. For more details on dependent fields, see Make a field dependent.

Note: You can reference all sysparm query parameters using either their full name or their shortened name (without the sysparm_ prefix). For example, for sysparm_limit you can also use limit.

URL format

Versioned URL: /api/sn_customerservice/{api_version}/case/field_values/ (field_name)

Default URL: /api/sn_customerservice/case/field_values/{field_name}

Supported request parameters

Path parameters

<table>

</thead>
</table>
| api_version     | Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.  
Data type: String |
| field_name      | Name of a choice or reference field in the Case [sn_customerservice_case] table.  
Data type: String |
### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_dependent_value</td>
<td>Value to select in the Case [sn_customerservice_case] table choice field that the requested field is dependent on. Use only when requesting a choice field that is dependent on another field. As an example, suppose you create a custom Channel Instance choice field in the Case table which is dependent on the default Channel choice field. When sysparm_dependent_value is not specified, this endpoint returns the full set of values for your custom field. To instead return only the subset of custom field values that are available when the Phone CSM channel is chosen from the Channel field, specify: sysparm_dependent_value=Phone. Data type: String</td>
</tr>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. Unusually large sysparm_limit values can impact system performance. For requests that exceed this number of records, use the sysparm_offset parameter to paginate record retrieval. Data type: Number</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, sysparm_offset is set to &quot;0&quot;. To simply page through all available records, sysparm_offset=sysparm_offset+sysparm_limit, until you reach the end of all records. Do not pass a negative number in the sysparm_offset parameter. Data type: Number Default: 0</td>
</tr>
<tr>
<td>sysparm_reference_field_columns</td>
<td>Comma-separated list of column names, from the table of the specified reference field, to return in the response. For example, if Contact is the specified reference field, you would include all of all the fields in the Contact table to return. Data type: String</td>
</tr>
</tbody>
</table>
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| **sysparm_query**     | Encoded query used to filter the result set. Queries defined using this parameter are appended to any encoded queries produced by reference qualifiers. For example:  

\`\{(sysparm_query=caller_id=javascript:gs.getUserID()^active=true)\`

The encoded query supports `order by`. To sort responses based on certain fields, use the `ORDERBY` and `ORDERBYDESC` clauses in `sysparm_query`. For example,  

\`\{sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory\`

filters all active records and orders the results in ascending order by number first, and then in descending order by category.

If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the property `glide.invalid_query.returns_no_rows`. Set this property to true to return no rows on an invalid query.

⚠️ **Note:** The `glide.invalid_query.returns_no_rows` property controls the behavior of all queries across the instance, such as in lists, scripts (`GlideRecord.query()`), and web service APIs.

Data type: String

| **sysparm_ref_qual_input** | Encoded set of field values representing a current object to reference qualifiers that use JavaScript functions. Use when requesting a reference field.

For example, when requesting values from the `Asset` field you can set this query parameter value to return only assets belonging to the specified product instead of assets belonging to the product associated with the specified case:

\`\{sysparm_ref_qual_input=product=5d1b7bb053401010dc25ddeeff7b129d\`

Data type: String

Syntax: `{field1}={value1}^{field2}={value2} […]`
### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Accept** | Data format of the response body. Supported types: `application/json` or `application/xml`.  
**Default:** `application/json` |

#### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Link** | REST response data can be split into multiple result sets. Where applicable, the response header contains different links for the first set, previous set, next set, and the last set of records.  
**For example:**  
https://<instance name>.service-now.com/api/now/table/cmdb_ci?sysparm_offset=40&sysparm_limit=10000;rel="next",  
https://<instance name>.service-now.com/api/now/table/cmdb_ci?sysparm_offset=40&sysparm_limit=10000;rel="prev",  
https://<instance name>.service-now.com/api/now/table/cmdb_ci?sysparm_offset=0&sysparm_limit=10000;rel="first",  
https://<instance name>.service-now.com/api/now/table/cmdb_ci?sysparm_offset=2780&sysparm_limit=10000;rel="last" |

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).
**Status codes**

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

**Response body parameters (JSON or XML)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Array of objects in which each object describes a single value for the requested field.</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td></td>
<td>&quot;result&quot;: [</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>&quot;label&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;value&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td>result.label</td>
<td>Display value for the field value.</td>
</tr>
<tr>
<td>result.value</td>
<td>Field value.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

Retrieve values for the contact reference field from all cases:

```bash
curl 'https://instance.servicenow.com/api/sn_customerservice/case/field_values/contact' 
--request GET 
--header 'Accept: application/json' 
--user 'username':'password'
```

The response displays labels and values for matching contacts:
Example: Python request
Retrieve values for the priority choice field from all cases:

```python
# Install requests package for python
import requests

# Set the API endpoint URL for the request
url = 'https://instance.servicenow.com/api/sn_customerservice/case/field_values/priority'

# Set the credentials
user = 'username'
pwd = 'password'

# Set the HTTP headers
```

headers = {"Accept": "application/xml"}

# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

The response shows labels and values for five matching priority field values:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <label>-- None --</label>
    <value/>
  </result>
  <result>
    <label>1 - Critical</label>
    <value>1</value>
  </result>
  <result>
    <label>2 - High</label>
    <value>2</value>
  </result>
  <result>
    <label>3 - Moderate</label>
    <value>3</value>
  </result>
  <result>
    <default_value>true</default_value>
    <label>4 - Low</label>
    <value>4</value>
  </result>
</response>
```

**Case - GET /sn_customerservice/case/{id}/field_values/{field_name}**

Retrieves the list of possible field values for a choice or reference field for a specified record in the Case [sn_customerservice_case] table.
To use this endpoint, users must have the csm_ws_integration, sn_customerservice.customer, or sn_customerservice.consumer role.

Use this endpoint to populate field value lists in case update forms.

When you request values for a reference field, any reference qualifiers defined for the requested field in the Dictionary Entry [sys_dictionary] table are applied, using values from the specified case record. For more information on reference qualifiers, see Reference qualifiers.

You can use the `sysparm_ref_qual_input` query parameter to override values from the specified case when evaluating JavaScript reference qualifiers. For an example, see the query parameter listing below.

When you request values for a choice field that is dependent on another field, this endpoint limits returned field values based on the dependency parent field value selected in the specified case record. For more details on dependent fields, see Make a field dependent.

You can use the `sysparm_dependent_value` query parameter to override the selection from the dependency parent field. For an example, see the query parameter listing below.

**Note:** You can reference all sysparm query parameters using either their full name or their shortened name (without the `sysparm_` prefix). For example, for `sysparm_limit` you can also use `limit`.

### URL format

**Versioned URL:** `/api/sn_customerservice/{api_version}/case/{id}/field_values/{field_name}`

**Default URL:** `/api/sn_customerservice/case/{id}/field_values/{field_name}`

### Supported request parameters

</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>Array of objects in which each object describes a single value for the requested field. Data type: Array</td>
</tr>
</tbody>
</table>

```
"result": [ 
  { 
    "label": "String", 
    "value": "String" 
  } 
]
```

result.label Display value for the field value.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Data type: String</th>
</tr>
</thead>
<tbody>
<tr>
<td>result.value</td>
<td>Field value.</td>
<td></td>
</tr>
</tbody>
</table>

**Example: cURL request**

Retrieve the contact reference field value for an existing case:

```bash
curl
  'https://instance.servicenow.com/api/sn_customerservice/case/f352dc9387632300d6b0a7da0acb0b60/field_values/contact' \
  --request GET \
  --header 'Accept: application/json' \
  --user 'username':'password'
```

The response displays the label and value for the contact assigned to the specified case:

```json
{
  "result": [
    {
      "label": "Alex Linde",
      "value": "60beb5e7d7600200e5982cf65e6103ad"
    }
  ]
}
```

**Example: Python request**

Retrieve values for the asset reference field, using the case with sys_id 4ac73c23c322310015519f2974d3aeeee when evaluating reference qualifiers:

```python
# Install requests package for python
import requests

# Set the API endpoint URL for the request
url = '
  'https://instance.servicenow.com/api/sn_customerservice/case/4ac73c23c322310015519f2974d3aeeee/field_values/asset'

# Set the credentials
user = 'username'
pwd = 'password'
```
# Set the HTTP headers
headers = {"Accept": "application/json"}

# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the JSON response into a dictionary and use the data
print(response.json())

The response shows labels and values for all assets belonging to the product associated with the specified case:

```
{
    "result": [
        {
            "label": "344-9448 - ACME KX Series - KX5000",
            "value": "b8defca16fc331003b3c498f5d3ee4e7"
        }
    ]
}
```

**Case - GET /sn_customerservice/case/{id}**

Retrieves the specified Customer Service Management (CSM) case.

To use this endpoint, users must have the csm_ws_integration, sn_customerservice.customer, or sn_customerservice.consumer role.

⚠️ **Note:** You can reference all sysparm query parameters using either their full name or their shortened name (without the `sysparm_` prefix). For example, for `sysparm_limit` you can also use `limit`.

**URL format**

- Versioned URL: /api/sn_customerservice/{api_version}/case/{id}
- Default URL: /api/sn_customerservice/case/{id}
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>id</td>
<td>Sys_id or case number for the case to retrieve. Located in the Case [sn_customerservice_case] table. Results will be unpredictable if a specified</td>
</tr>
<tr>
<td></td>
<td>case number is shared by two or more cases.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_display_value</td>
<td>Data retrieval operation for reference and choice fields.</td>
</tr>
<tr>
<td></td>
<td>Based on this value, retrieves the display value and/or the actual value from the database.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Returns the display values for all fields.</td>
</tr>
<tr>
<td></td>
<td>• false: Returns the actual values from the database.</td>
</tr>
<tr>
<td></td>
<td>• all: Returns both actual and display values.</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
</tbody>
</table>

**Note:** There is no preferred method for setting this parameter. However, specifying the display value may cause performance issues since it is not reading directly from the database and may include referencing other fields and records. For more information on display values and actual values, see Table API FAQs (KB0534905).

Data type: String  
Maximum length: 100 |
Data type: String |
Data type: String |
<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
</table>
| description | Detailed description of the problem associated with the case. | Data type: String  

Maximum length: 4,000 |
| due_date   | Date that the case is due to be closed.                                                                                                     |
Entitlements define the type of support that a customer receives as well as the supported communication channels. An entitlement can be associated with a product, an asset, an account, or a contract. |
| escalation | Current escalation level.  
Possible values:  
• 0: Normal  
• 1: Moderate  
• 2: High  
• 3: Overdue                                                                                                                                            |
| expected_start | Date and time when work is scheduled to begin on the case.                                                                                   |
|              | Data type: String  

Default: 0 |
<table>
<thead>
<tr>
<th><strong>Element</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
</table>
| first_response_time | Date and time when the first action was taken on the case.  
Data type: String                                                                                                                                       |
| follow_the_sun   | Flag that indicates whether the case should be handed off for global follow-up.  
If a customer enters additional comments on a Priority 1 - Critical or a Priority 2 - High case, or if the case is escalated, the flag is automatically set to true.  
Possible values:  
• true: Case should be handed-off for global follow-up  
• false: Case should not be handed-off for global follow-up  
Data type: Boolean  
Default: false                                                                                     |
| follow_up        | Date and time of the next follow up action.

</table>

**Example: cURL request**

```bash
curl 
  "https://instance.servicenow.com/api/sn_customerservice/case/ba325dbe64f01300964fae39b050e9a6" \ 
--request GET \ 
--header "Accept:application/json" \ 
--user "username":"password"

{ 
 "result": {
```
"close_notes": "",
"sys_id": "ba325dbe64f01300964fae39b050e9a6",
"contact_type": "web",
"resolution_code": "",
"probable_cause": "",
"urgency": "3",
"company": "",
"major_case_state": "accepted",
"consumer": "",
"activity_due": "",
"comments": "",
"approval": "not requested",
"due_date": "",
"sys_mod_count": "2",
"sys_tags": "",
"active_account_escalation": "",
"location": "",
"category": "1",
"account": ""
}

Example: Python request
This request retrieves a case, with sysparm_display_value set to "all" to retrieve display and literal field values.

```python
# Install requests package for python
import requests

# Set the API endpoint URL for the request
url = 'https://instance.servicenow.com/api/sn_customerservice/v1/case/09ba659a0b412300c9c86c9037673af4'

# Set the credentials
user = 'username'
pwd = 'password'

# Set the query parameters
params = {'sysparm_display_value': 'all'}

# Set the HTTP headers
headers = {'Accept': 'application/xml'}
```
# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), params=params, headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
    response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

Because `sysparm_display_value` is set to "all", the response includes literal values and display values for each field. Removing this parameter or setting its value to "false" retrieves literal database values.

```xml
<response>
  <result>
    <parent>
      <display_value/>
      <name>parent</name>

**Case - GET /sn_customerservice/case**

Retrieves a specified set of Customer Service Management (CSM) cases.

To use this endpoint, users must have the csm_ws_integration, sn_customerservice.customer, or sn_customerservice.consumer role.

**Note:** You can reference all sysparm query parameters using either their full name or their shortened name (without the `sysparm_` prefix). For example, for `sysparm_limit` you can also use `limit`.

**URL format**

Versioned URL: /api/sn_customerservice/{api_version}/case

Default URL: /api/sn_customerservice/case
**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, <code>v1</code> or <code>v2</code>. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_display_value</td>
<td>Data retrieval operation for reference and choice fields. Based on this value, retrieves the display value and/or the actual value from the database.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• true: Returns the display values for all fields</td>
</tr>
<tr>
<td></td>
<td>• false: Returns the actual values from the database</td>
</tr>
<tr>
<td></td>
<td>• all: Returns both actual and display values</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> There is no preferred method for setting this parameter. However, specifying the display value may cause performance issues since it is not reading directly from the database and may include referencing other fields and records. For more information on display values and actual values, see Table API FAQs (KB0534905).</td>
</tr>
<tr>
<td>sysparm_fields</td>
<td>Comma-separated list of fields to return in the response.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. Unusually large <code>sysparm_limit</code> values can impact system performance. For requests that exceed this number of records, use the <code>sysparm_offset</code> parameter to paginate record retrieval.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, <code>sysparm_offset</code> is set to &quot;0&quot;. To simply page through all available records, use <code>sysparm_offset=sysparm_offset+sysparm_limit</code>, until you reach the end of all records. Do not pass a negative number in the <code>sysparm_offset</code> parameter. Data type: Number Default: 0</td>
</tr>
<tr>
<td>sysparm_query</td>
<td>Encoded query used to filter the result set. For example: <code>{sysparm_query=caller_id=javascript:gs.getUserID()^active=true}</code> The encoded query supports order by. To sort responses based on certain fields, use the ORDERBY and ORDERBYDESC clauses in <code>sysparm_query</code>. For example, <code>sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory</code> filters all active records and orders the results in ascending order by number first, and then in descending order by category. If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the property <code>glide.invalid_query.returns_no_rows</code>. Set this property to true to return no rows on an invalid query. Data type: String</td>
</tr>
<tr>
<td>sysparm_reference_fields</td>
<td>Whether or not to retrieve fields from reference tables such as account, contact, consumer, and sn_app_cs_social_social_profile. By default, these fields are returned if the user has read access to them, but this adds...</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>performance overhead. When retrieving a large number of case records, this overhead can be eliminated by setting sysparm_reference_fields=false.</td>
</tr>
<tr>
<td>Data type: Boolean</td>
<td></td>
</tr>
<tr>
<td>Default: true</td>
<td></td>
</tr>
</tbody>
</table>

Note: When using this endpoint, you can omit the sysparm_ prefix for this query parameter and specify it as reference_fields.

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Link</td>
<td>REST response data can be split into multiple result sets. Where applicable, the response header contains different links for the first set, previous set, next set, and the last set of records. For example:</td>
</tr>
</tbody>
</table>
Response headers (continued)

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>https://&lt;instance name&gt;.service-now.com/api/now/table/cmdb_ci?sysparm_offset=40&amp;sysparm_limit=10000&gt;;rel=&quot;next&quot;</td>
<td></td>
</tr>
<tr>
<td>https://&lt;instance name&gt;.service-now.com/api/now/table/cmdb_ci?sysparm_offset=40&amp;sysparm_limit=10000&gt;;rel=&quot;prev&quot;</td>
<td></td>
</tr>
<tr>
<td>https://&lt;instance name&gt;.service-now.com/api/now/table/cmdb_ci?sysparm_offset=0&amp;sysparm_limit=10000&gt;;rel=&quot;first&quot;</td>
<td></td>
</tr>
<tr>
<td>https://&lt;instance name&gt;.service-now.com/api/now/table/cmdb_ci?sysparm_offset=2780&amp;sysparm_limit=10000&gt;;rel=&quot;last&quot;</td>
<td></td>
</tr>
<tr>
<td>X-Total-Count</td>
<td>Response header showing the total number of records matching the request when the sysparm_limit or sysparm_offset query parameters are specified.</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>account</td>
<td>Sys_id of the account record associated with the case. Located in the Account [customer_account] table. Data type: String</td>
</tr>
<tr>
<td>account</td>
<td>Account details.</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>Data type</strong>: Object</td>
<td></td>
</tr>
</tbody>
</table>

**Example: cURL request**

Retrieve the third and fourth CSM cases listed for a specific account.

```bash
curl
  "https://instance.servicenow.com/api/sn_customerservice/case?sysparm_query=account=86837a386f0331003b3c498f5d3ee4ca&sysparm_limit=2&sysparm_offset=2" \
  --request GET \
  --header "Accept:application/json" \
  --user "username":"password"
```

The response shows the two cases.

Example: Python request

This request retrieves the seventh and eighth cases for a customer account, with display values instead of literal database values.

```python
# Install requests package for python
import requests

# Set the API endpoint URL for the request
url = 'https://instance.servicenow.com/api/sn_customerservice/case'

# Set the credentials
user = 'username'
pwd = 'password'

# Set the query parameters
params = {
    "sysparm_display_value": "true",
    "sysparm_query": "account=86837a386f0331003b3c498f5d3ee4ca",
    "sysparm_limit": 2,
    "sysparm_offset": 6
}

# Set the HTTP headers
```
headers = {"Accept": "application/xml"}

# Issue the HTTP request
response = requests.get(url, auth=(user, pwd), params=params, headers=headers)

# Check for HTTP status codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

Because `sysparm_display_value` is set to "true", the response includes display values, such as the state value of "Open," instead of literal database values. Removing this parameter or setting its value to "false" retrieves literal database values.

```xml

**Case - POST /sn_customerservice/case**

Creates a new Customer Service Management (CSM) case.

To use this endpoint, users must have the csm_ws_integration, sn_customerservice.customer, or sn_customerservice.consumer role.
You can create different types of cases depending on whether you are working in a business-to-business (B2B) or business-to-consumer (B2C) environment, or creating a case for an order or product.

In addition, you can create a social media profile for a contact, consumer, or account using this endpoint. To create a social media profile, you must specify the following parameters in the request body:

- `social_channel`
- `social_handle`
- `social_handle_type`
- `social_handle_url`
- `social_post_url`

All request body parameters are optional. Some parameters are only valid in one environment or the other (B2B or B2C), and are noted as such in the request body parameter descriptions. If you specify a contact, the account, case report, contract, and entitlement parameters are defaulted to the values defined in the contact/account records. If you specify an account, the case report, contract, and entitlement parameters are defaulted to the values defined in the account record (unless overridden by passed in parameters.) If you do not pass any parameters to the endpoint, the case record is created with only default information (defined in the table below) and instance generated values (`sys_*`). All other parameters are set with their equivalent of a null value. In addition to the list of parameters defined below, which define the parameters found in a base system, the endpoint also accepts custom case fields and any additional case fields configured in your instance. For additional information on these elements, refer to your specific table definitions [System Definition > Tables].

⚠️ **Warning:** This endpoint does not perform parameter validation as doing so can create excessive overhead. If a request parameter is misspelled, is not valid for the type of case, or is not supported by the endpoint, it is either ignored without warning or can cause unexpected results. For example, if you create a consumer or contact for the wrong type of case or mismatch a contact with an account.

⚠️ **Warning:** By default, external users who have the `sn_customerservice.customer` or `sn_customerservice.consumer` role can only set the account, asset, comments, consumer, contact, contact_type, partner, partner_contact, priority, product, short_description, and state fields using this endpoint.
**Note:** You can reference all `sysparm` query parameters using either their full name or their shortened name (without the `sysparm_` prefix). For example, for `sysparm_limit` you can also use `limit`.

**URL format**

Versioned URL: `/api/sn_customerservice/{api_version}/case`

Default URL: `/api/sn_customerservice/case`

**Supported request parameters**

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Only supports application/json.</td>
</tr>
<tr>
<td>Content-Type</td>
<td>Data format of the request body. Only supports application/json.</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>201</td>
<td>New case record was successfully created.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>
### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number</td>
<td>Associated case number.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the new case record created in the Case [sn_customerservice_case] table.</td>
</tr>
</tbody>
</table>

**Data type:** String

#### Example: cURL request

The following example illustrates how to create a case based on a consumer and also create a new social media account that is associated with the case.

```bash
curl "https://instance.servicenow.com/api/sn_customerservice/case" \
--request POST \
--header "Accept:application/json" \
--header "Content-Type:application/json" \
--data "{" 
  consumer: "cd97ef1ddb8bc7006b7a9646db9619ac", 
  contact_type: "social", 
  priority: "4", 
  short_description: "Consumer Test Case", 
  social_channel: "TWITTER", 
  social_handle: "consumertwo", 
  social_handle_type: "Consumer", 
  social_handle_url: "https://www.twitter.com/consumertwo", 
  social_post_url: "https://twitter.com/MuleSoft/status/829092185022750720"}" \
--user "username":"password"
```

```json
{
  "result": {
    "sys_id": "0397c743db436f0057c3fd441d96197f",
    "number": "CS0001005"
  }
}
```

#### Example: cURL request

The following example illustrates how to create a case for an account.

```bash
curl "https://instance.servicenow.com/api/sn_customerservice/case" \
--request POST \
--header "Accept:application/json" \
--header "Content-Type:application/json"
```
---header "Accept:application/json" \
---header "Content-Type:application/json" \
---data "{ \
    account: "051f62b0d7300200e5982cf65e610333", \
    contact_type: "phone", \
    priority: "1", \
    short_description: "Power Outage"}" \
---user "username":"password"

{
    "result": {
        "sys_id": "b88366ffdb1b0b00216e9ee6db96190b",
        "number": "CS0001021"
    }
}

Example: cURL request
The following example illustrates how to create a case for a specific contact. Note that if an account is specified within the contact record, that account is automatically assigned to the case.

curl "https://instance.servicenow.com/api/sn_customerservice/case" \
  --request POST \
  --header "Accept:application/json" \
  --header "Content-Type:application/json" \
  --data "{ \
      contact: "62fe1c97db76c3006b7a9646db961999",
      contact_type: "phone", 
      priority: "3",
      short_description: "Power Outage"}" \
  --user "username":"password"

{
    "result": {
        "sys_id": "bf916affdb1b0b00216e9ee6db961937",
        "number": "CS0001013"
    }
}

Example: Python request

# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_customerservice/case'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {"Content-Type":"application/json", "Accept":"application/json"}

# Make the HTTP request
response = requests.post(url, auth=(user, pwd), headers=headers, data="{"contact":"62fe1c97db76c3006b7a9656db961999"}")

# Check for HTTP codes other than 201
if response.status_code != 201:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()

print(data)

{
    "result": {
        "sys_id":"c7940ed1db9ba30057c3fd41d961967",
        "number":"CS0001074"
    }
}

**Case - PUT /sn_customerservice/case/{id}**

Updates the specified existing Customer Service Management (CSM) case with the passed-in parameters.

⚠️ **Warning:** This endpoint does not perform parameter validation as doing so can create excessive overhead. If a request parameter is misspelled, is not valid for the type of case, or is not supported by the endpoint, it is either ignored without warning or can cause unexpected results. For example, if you create a consumer or contact for the wrong type of case or mismatch a contact with an account.
**Warning:** By default, external users who have the sn_customerservice.customer or sn_customerservice.consumer role can only set the comments and state fields using this endpoint. Admins can enable external users to set additional fields by specifying the field names in the UPDATE_ALLOWED_FIELDS array defined in the CaseRESTAPIValidatorForExternalUser script include. Exercise caution when adding new fields to this array, as there may not be existing validators for input into those fields. For more information on script includes, see Script includes.

**Note:** You can reference all sysparm query parameters using either their full name or their shortened name (without the sysparm_prefix). For example, for sysparm_limit you can also use limit.

**URL format**

Versioned URL: /api/sn_customerservice/{api_version}/case/{id}

Default URL: /api/sn_customerservice/case/{id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>id</td>
<td>Sys_id of the case to update. Located in the Case [sn_customerservice_case] table.</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_display_value</td>
<td>Data retrieval operation for reference and choice fields. Based on this value, retrieves the display value and/or the actual value from the database.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td></td>
<td>Valid values:</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• true: Returns the display values for all fields.</td>
</tr>
<tr>
<td></td>
<td>• false: Returns the actual values from the database.</td>
</tr>
<tr>
<td></td>
<td>• all: Returns both actual and display values.</td>
</tr>
<tr>
<td>Default: false</td>
<td>Note: There is no preferred method for setting this parameter. However, specifying the display value may cause performance issues since it is not reading directly from the database and may include referencing other fields and records. For more information on display values and actual values, see Table API FAQs (KB0534905).</td>
</tr>
</tbody>
</table>

| sysparm_fields     | Comma-separated list of fields to return in the response.                |
|--------------------| Data type: String                                                        |
| sysparm_get_case_details | Flag that indicates whether to return the updated case record.        |
|                    | Valid values:                                                            |
|                    | • true: Return updated case record.                                       |
|                    | • false: Do not return the updated case record.                          |
| Data type: Boolean | Default: false                                                           |

<tr>
<td>work_notes_list</td>
<td>List of sys_ids of the internal users who receive notifications about this case when work notes are added. Located in the [sys_user] table. Data type: Array</td>
</tr>
<tr>
<td>work_start</td>
<td>Date and time that work started on the case. Data type: String</td>
</tr>
</tbody>
</table>

**Notes on request body parameters**

All request body parameters are optional. Not all parameters apply to all case types (B2B vs B2C and order vs product.) Ensure that the parameters that you
set do not conflict, such as a mismatch between the account and contact or consumer. In addition to the list of elements defined below (which define the elements found in a base system), the endpoint also accepts custom case fields and any additional case fields configured in your instance. For additional information on these elements, refer to your specific table definitions [System Definition > Tables].

Example: cURL request
The following example illustrates how to update a consumer-based case.

```
curl  
"https://instance.servicenow.com/api/sn_customerservice/case/0397c743db436f0057c3fd441d96197f"  
--request PUT  
--header "Accept:application/json"  
--header "Content-Type:application/json"  
--data "{"  
  consumer: "cd97ef1dddb8bc7006b7a9646db9619ac",  
  contact_type: "phone",  
  priority: "4",  
  short_description: "Consumer Test Case"}"  
--user "username":"password"
```

```
{
  "result": {
    "sys_id": "0397c743db436f0057c3fd441d96197f",
    "number": "CS0001005"
  }
}
```

Example: Python request
```
# Install requests package for python
import requests

# Set the request parameters
url =  
'https://instance.servicenow.com/api/sn_customerservice/case/c7940ed1db9ba30057c3fd441d961967'

# Set the user credentials
user = 'username'
pwd = 'password'
```
# Set the proper headers
headers = {"Content-Type":"application/json","Accept":"application/json"}

# Make the HTTP request
response = requests.put(url, auth=(user, pwd), headers=headers, data="{"contact":"62fe1c97db76c3006b7a9646db961999"}"

# Check for HTTP codes other than 201
if response.status_code != 201:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

{
    "result": {
        "sys_id": "c7940ed1db9ba30057c3fd441d961967",
        "number": "CS0001074"
    }
}

**Change Management API**

The Change Management API provides REST APIs that enable third-party application integration with the ServiceNow Change Management process.

By integrating your application with the ServiceNow Change Management process, all change requests, regardless of where they are initiated, have a single source of truth, providing a single audit source.

Use this REST API to integrate your change management process with external applications and when developing ServiceNow client-side applications.

This REST API enables integrators to:

- Initiate a standard change request from a published standard change request template.
- Create a change request of type emergency or normal.
- Update any field that exists in the change request table for any change request.
- Update any field that exists in the change task table and work tasks from creation through closure/cancellation.
• Retrieve a specific change request, standard template, change request task, or change model.
• Retrieve multiple change requests, standard templates, change request tasks using pagination.
• Perform risk evaluation.
• Refresh impacted services.
• Generate and process any related approval activity associated with a change request.
• Identify potential scheduling conflicts and identify periods where conflicts do not exist.
• Delete change requests, change request tasks, and conflict checking processes.
• Create a change request record based on a change model record.

The Change REST API supports ITIL types and Change models using Flow Designer and Workflow. Change models deliver fit-for-purpose change. Types and models define transition criteria that must be met before the change request can progress to the next state. You can define this criteria using states, workflows, tools, and business rules.

• Traditional ITIL types: Standard, Emergency, and Normal.
• Change model states: New, Scheduled, Implement, Review, and Closed.

You can configure additional change models within your ServiceNow instance and then create change requests based on those change models using endpoints in this API. Use the Change Management - GET /sn_chg_rest/change/model/{sys_id} and Change Management - GET /sn_chg_rest/change/model endpoints to obtain the available change models in an instance. Then use the Change Management - POST /sn_chg_rest/change to create a change request based on a specified change model.

For information on configuring change models, see Configure Change Management.

The following roles are required to access the Change Management endpoints:
• DELETE: change_manager or admin
• GET: change_manager, itil, sn_change_read, or admin
• PATCH/POST: change_manager, itil, or admin
In addition, administrators can set change properties to configure Change Management behavior. For a list of these properties and a description of their available functionality, see Change Management properties.

Change Management - DELETE /sn_chg_rest/change/{change_sys_id}/task/{task_sys_id}

Deletes the change request task identified by the specified sys_ids.

**URL format**

**Versioned URL:** /api/sn_chg_rest/{api_version}/change/{change_sys_id}/task/{task_sys_id}

**Default URL:** /api/sn_chg_rest/change/{change_sys_id}/task/{task_sys_id}

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>change_sys_id</td>
<td>Sys_id of the change request to which the task is associated. Located in the Change Request [change_request] table. Verifies that the task is actually associated to the specified change request. Data type: String</td>
</tr>
<tr>
<td>task_sys_id</td>
<td>Sys_id of the change request task to delete. Located in the Change Tasks [change_task] table. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>
## Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>All fields (key) with their associated values for the identified change request task prior to the delete. Data type: Object</td>
</tr>
<tr>
<td>parent</td>
<td>Information for the change request to which this task was associated. Data type: Object</td>
</tr>
<tr>
<td>parent.display_value</td>
<td>Sys_id of the parent task to display in a UI. Data type: String</td>
</tr>
<tr>
<td>parent.value</td>
<td>Sys_id of the parent task. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id information for the deleted change request. Data type: Object</td>
</tr>
<tr>
<td>sys_id.display_value</td>
<td>Sys_id of the change request to display in a UI. Data type: String</td>
</tr>
<tr>
<td>sys_id.value</td>
<td>Sys_id of the change request. Data type: String</td>
</tr>
</tbody>
</table>

### Example: cURL request

```bash
curl "https://instance.servicenow.com/api/sn_chg_rest/v1/change/0f4ac6c4b750230096c3e4f6ee1ia9fe/task/12629ec4b750230096c3e4f6ee1ia9d5" \
--request DELETE 
```
Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_chg_rest/v1/change/0f4ac6c4b750230096c3e4f6ee11a9fe/task/12629ec4b750230096c3e4f6ee11a9d5'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept':'application/json'}

# Make the HTTP request
response = requests.delete(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
```
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
    response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <sys_id>
      <value>12629ec4b750230096c3e4f6ee11a9d5</value>
      <display_value>12629ec4b750230096c3e4f6ee11a9d5</display_value>
    </sys_id>
    <parent>
      <value>0f4ac6c4b750230096c3e4f6ee11a9fe</value>
      <display_value>CHG0033046</display_value>
    </parent>

    // all valid fields in record, single parameter example below
    <short_description>
      <value>Retire both nodes</value>
      <display_value>Retire both nodes</display_value>
    </short_description>
  </result>
</response>

Change Management - DELETE /sn_chg_rest/change/{sys_id}
Deletes the change request associated with the specified sys_id.

URL format
Versioned URL: /api/sn_chg_rest/{api_version}/change/{sys_id}
Default URL: /api/sn_chg_rest/change/{sys_id}
Supported request parameters

Path parameters

<table>
<thead>
<tr>

**Change Management - DELETE /sn_chg_rest/change/{sys_id}/conflict**

Cancels the running conflict checking process for the specified change request (sys_id).

**URL format**

Versioned URL: /api/sn_chg_rest/{api_version}/change/{sys_id}/conflict

Default URL: /api/sn_chg_rest/change/{sys_id}/conflict

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the change request record for which to cancel the running conflict checking process. Located in the Change Request [change_request] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Request body parameters (XML or JSON)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Headers
The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>

<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
**Example: cURL request**

```bash
curl
  "https://instance.servicenow.com/api/sn_chg_rest/v1/change/0f4ac6c4b750230096c3e4f6ee11a9fe/conflict" \
  --request DELETE \
  --user "username":"password"
```

**Example: Python request**

```python
# Install requests package for python
import requests

# Set the request parameters
url =
  'https://instance.servicenow.com/api/sn_chg_rest/v1/change/0f4ac6c4b750230096c3e4f6ee11a9fe/conflict'

# Set the user credentials
user = 'username'
pwd = 'password'

# Make the HTTP request
response = requests.delete(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()
```

**Change Management - DELETE /sn_chg_rest/change/emergency/{sys_id}**

Deletes the emergency change request identified by the specified sys_id.

**URL format**

Versioned URL: `/api/sn_chg_rest/{api_version}/change/emergency/{sys_id}`

Default URL: `/api/sn_chg_rest/change/emergency/{sys_id}`
Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>

</table>
## Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](rest-api-http-response-codes).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

## Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Values for all fields in the associated change request. Data type: Object</td>
</tr>
<tr>
<td>state</td>
<td>State of the change request prior to the delete. Data type: Object</td>
</tr>
<tr>
<td>state.display_value</td>
<td>State to display in the UI. Data type: String</td>
</tr>
<tr>
<td>state.value</td>
<td>Internal state value. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id information for the change request. Data type: Object</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sys_id.display_value</td>
<td>Sys_id of the change request to display in a UI.</td>
</tr>
<tr>
<td>sys_id.value</td>
<td>Sys_id of the change request.</td>
</tr>
<tr>
<td>type</td>
<td>Type of change request.</td>
</tr>
<tr>
<td>type.display_value</td>
<td>Change type to display in a UI.</td>
</tr>
<tr>
<td>type.value</td>
<td>Internal type value.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```bash
curl "https://instance.servicenow.com/api/sn_chg_rest/v1/change/emergency/b0dbda5347c12200e0ef563dbb9a718f" \
--request DELETE \
--header "Accept:application/json" \
--user "username":"password"
```

```
{
  result: [
    {
      sys_id: {
        value: "b0dbda5347c12200e0ef563dbb9a718f",
        display_value: "b0dbda5347c12200e0ef563dbb9a718f"
      }
    }
  ]
}
```
Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_chg_rest/v1/change/emergency/b0dbda5347c12200e0ef563dbb9a718f'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept': 'application/xml'}

# Make the HTTP request
response = requests.delete(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()
```

# Decode the XML response into a dictionary and use the data
print(response.content)

```xml
<response>
  <result>
    <sys_id>
      <value>b0dbda5347c12200e0ef563dbb9a718f</value>
      <display_value>b0dbda5347c12200e0ef563dbb9a718f</display_value>
    </sys_id>
    <state>
      <value>-5</value>
      <display_value>New</display_value>
    </state>
    <type>
      <value>emergency</value>
      <display_value>Emergency</display_value>
    </type>
    // all valid fields in record, single parameter example below
    <short_description>
      <value>Remove server</value>
      <display_value>Remove server</display_value>
    </short_description>
  </result>
</response>
```

### Change Management - DELETE /sn_chg_rest/change/normal/{sys_id}

Deletes the normal change request identified by the specified sys_id.

### URL format

**Versioned URL:** /api/sn_chg_rest/{api_version}/change/normal/{sys_id}

**Default URL:** /api/sn_chg_rest/change/normal/{sys_id}

### Supported request parameters

#### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
</tbody>
</table>
### Path parameters (continued)

<table>

      <value>Add network switch to cabinet</value>
      <display_value>Add network switch to cabinet</display_value>
    </short_description>
  </result>
</response>
```
Change Management - GET /sn_chg_rest/change/ci/{cmdb_ci_sys_id}/schedule

Enables retrieving available time slots by configuration item ID and duration, with an option to include planned start time.

Role required: sn_change_writer

⚠️ Note: Running this endpoint does not list the available start and end times. Use the link provided in the response body `worker.link` property to get the schedule data.

See also:
- GET /sn_chg_rest/change/{change_sys_id}/schedule
- PATCH /sn_chg_rest/change/{change_sys_id}/schedule/first_available

**URL format**

**Versioned URL:** /api/sn_chg_rest/{api_version}/change/ci/{cmdb_ci_sys_id}/schedule

**Default URL:** /api/sn_chg_rest/change/ci/{cmdb_ci_sys_id}/schedule

**Supported request parameters**

### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>cmdb_ci_sys_id</td>
<td>Sys_id of a record in the Configuration Items [cmdb_ci] table. This endpoint does not require a change request.</td>
</tr>
</tbody>
</table>

### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>duration_in_seconds</td>
<td>Duration of change in seconds, that is, how much time is required to complete the change request task.</td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>planned_start_time</td>
<td>Optional. Date and time that the change request is planned to start implementation in UTC. Retrieve the available time slot start at or later than this time. If not provided, the system uses the current time as the start time. Time format: yyyy-mm-dd hh:mm:ss</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>

</tr>
<tr>
<td>worker</td>
<td>Information about the associated worker.</td>
</tr>
<tr>
<td>worker.link</td>
<td>Link for retrieving time slot data. Use the sys_id in GET /sn_chg_rest/change/worker/{sys_id} to view results.</td>
</tr>
<tr>
<td>worker.sysId</td>
<td>Sys_id of the worker associated with the change request.</td>
</tr>
<tr>
<td>status</td>
<td>Only appears if an error is encountered. Status of the endpoint processing. Possible values: failure</td>
</tr>
</tbody>
</table>

### Get available time slots

Use the value provided in the `worker.link` to get schedule window details. The value is in the following format:

```
https://instance.service-now.com/api/sn_chg_rest/change/worker/<worker_sys_id>
```

Use the `worker_sys_id` in GET /sn_chg_rest/change/worker/{sys_id} to view results.

The response body contains the status and provides results when processing is complete.
Worker response body parameter results vary depending on time slot availability.

- If the provided time slot is available for the change request within the schedule time slot, the worker API lists the available time slots in the `payload.spans` property. The `payload.spans` property is not listed in the results otherwise.

- If there are no time slots available for change request duration provided within the defined scheduling time slot, the `messages.infoMessages` states the following:

  No slots found for <number> days from <date and time in format yyyy-mm-dd hh:mm:ss>

  **Note:** The change request scheduling time slot default value is 90 days. To change this value, modify the `change.conflict.next_available.schedule_window` property. For more information, see Configure conflict analysis properties.

The following GET `/sn_chg_rest/change/worker/{sys_id}` example shows output provided using the ID provided in the worker.link detail. The results list open time spans available for the task duration.

```json
{
  "result": {
    "worker": {
      "sysId": "d7d1f2b4a444b010f87712198fe9caae",
      "link": "https://instance.service-now.com/api/sn_chg_rest/change/worker/d7d1f2b4a444b010f87712198fe9caae"
    },
    "request": {

Example: cURL request

curl
"https://instance.service-now.com/api/sn_chg_rest/change/ci/<cmdb_ci_sys_id>/schedule?duration_in_seconds=10800" \
--request GET \
--header "Accept:application/json" \
--user "username":"password"

Results include worker.link details you can use to run the provided sys_id in the GET /sn_chg_rest/change/worker/ endpoint.

{
    "result": {
        "worker": {
            "sysId": "1049419c1b4c3010f58a6572604bcb7a",
        }
    }
}
Change Management - GET /sn_chg_rest/change

Retrieves one or more change requests based on the specified criteria.

**URL format**

Versioned URL: /api/sn_chg_rest/{api_version}/change

Default URL: /api/sn_chg_rest/change

**Supported request parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>
### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Name-value pairs to use to filter the result set. The name is the field on which the specified value is filtered. This parameter is mutually exclusive with <strong>sysparm_query</strong>. For example, instead of using &amp;sysparm_query=active=true, you can simplify the calling statement by using &amp;active=true. You can also use the display value when the field is a choice or reference type field, such as &amp;state=closed instead of &amp;state=7. To specify multiple key-value pairs, separate each with an ampersand, such as &amp;active=true&amp;assigned_to=john.smith. Data type: String</td>
</tr>
<tr>
<td>order</td>
<td>Field by which to sort the returned change requests.</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, <strong>sysparm_offset</strong> is set to &quot;0&quot;. Simply page through all available records, use <strong>sysparm_offset=sysparm_offset+sysparm_limit</strong>, until you reach the end of all records. Do not pass a negative number in the <strong>sysparm_offset</strong> parameter. Data type: Number Default: 0</td>
</tr>
</tbody>
</table>
| sysparm_query         | Encoded query used to filter the result set. **Syntax:** sysparm_query=<col_name><operator><value>.  
  - **<col_name>:** Name of the table column to filter against.  
  - **<operator>:** Supports the following values:  
    - =: Exactly matches <value>.  
    - !=: Does not match <value>.  
    - ^: Logically AND multiple query statements.  
    - ^OR: Logically OR multiple query statements.  
    - LIKE: <col_name> contains the specified string. Only works for <col_name> fields whose data type is string. |
**Query parameters (continued)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>STARTSWITH</strong>:</td>
<td>&lt;col_name&gt; starts with the specified string. Only works for &lt;col_name&gt; fields whose data type is string.</td>
</tr>
<tr>
<td><strong>ENDSWITH</strong>:</td>
<td>&lt;col_name&gt; ends with the specified string. Only works for &lt;col_name&gt; fields whose data type is string.</td>
</tr>
<tr>
<td><strong>&lt;value&gt;</strong>:</td>
<td>Value to match against.</td>
</tr>
</tbody>
</table>

All parameters are case-sensitive. Queries can contain more than one entry, such as
```
sysparm_query=<col_name><operator><value>[<operator><col_name><operator><value>]
```
For example:
```
(sysparm_query=caller_id=javascript:gs.getUserID()^active=true)
```
Encoded queries also supports order by functionality. To sort responses based on certain fields, use the ORDERBY and ORDERBYDESC clauses in `sysparm_query`.

**Syntax:**
- ORDERBY<col_name>
- ORDERBYDESC<col_name>

**For example:** `sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory`

This query filters all active records and orders the results in ascending order by number, and then in descending order by category.

If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the property `glide.invalid_query.returns_no_rows`. Set this property to true to return no rows for invalid queries.

**Note:** The `glide.invalid_query.returns_no_rows` property controls the behavior of all queries across the instance, such as in lists, scripts (`GlideRecord.query()`), and web service APIs.

**Data type:** String

<table>
<thead>
<tr>
<th>textSearch</th>
<th>String to use to search all normal change request record fields. This search uses ServiceNow full text search platform functionality. For more information on ServiceNow search capabilities, see <a href="#">Search administration</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Default:</strong></td>
<td>IR_AND_OR_QUERY</td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

**Response headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

**Status codes**

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>
Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>List containing one or more change request record objects. Each object describes a change request. Each element in the change request object corresponds to a field in its associated record in the Change Request [change_request] table. All elements contain value and display_value name-value pairs. Date fields also contain display_value_internal name-value pairs. Data type: Array</td>
</tr>
</tbody>
</table>
| action_status | Current action status of the associated change request. Possible values:  
  • 1: Blocked internally  
  • 2: Blocked by customer  
  • 3: Blocked internally and by customer  
  • 4: Needs attention  
Data type: Number                                                                                                         |
| active        | Flag that indicates whether the change request is active. Possible values:  
  • true: Change request is active  
  • false: Change request is not active  
Data type: Boolean  
Default: true                                                                                                              |
| activity_due  | Date and time for which the associated case is expected to be completed.  
Data type: String                                                                                                          |
<table>
<thead>

Change Management - GET /sn_chg_rest/change/{change_sys_id}/schedule

Enables retrieving the available time slots for a change request.

Role required: sn_change_writer

Note: Running this endpoint does not list the available start and end times. Use the link provided in the response body `worker.link` property to get the schedule data.

See also:
- GET /sn_chg_rest/change/ci/{cmdb_ci_sys_id}/schedule
- PATCH /sn_chg_rest/change/{change_sys_id}/schedule/first_available

**URL format**

Versioned URL: /api/sn_chg_rest/{api_version}/change/{change_sys_id}/schedule

Default URL: /api/sn_chg_rest/change/{change_sys_id}/schedule

**Supported request parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td>change_sys_id</td>
<td>Sys_id of the change request on which to find the next available time slot. Located in the [change_request] table. The selected change request must have a configuration item (cmdb_ci) with planned start and planned end times.</td>
</tr>
</tbody>
</table>
Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>202</td>
<td>System accepted the request.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected. Possible issues:</td>
</tr>
</tbody>
</table>
### Status codes (continued)

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- The specified change request is missing the planned start and end times.</td>
</tr>
<tr>
<td></td>
<td>- The specified change request does not have an associated configuration item (cmdb_ci).</td>
</tr>
<tr>
<td></td>
<td>- User does not have read access to the fields of the change request.</td>
</tr>
<tr>
<td>404</td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td></td>
<td>Possible issues:</td>
</tr>
<tr>
<td></td>
<td>- System cannot find the change request based on information provided.</td>
</tr>
<tr>
<td></td>
<td>- User does not have read access to the record.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error</td>
<td>Information on any errors encountered while processing the endpoint request.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>
<td>&quot;error&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;detail&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;message&quot;: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;status&quot;: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>error.detail</td>
<td>Additional information about the error.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>error.message</td>
<td>Message that identifies the error.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>messages</td>
<td>Message information.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>
<td>&quot;messages&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;errorMessages&quot;: [Array],</td>
</tr>
<tr>
<td></td>
<td>&quot;infoMessages&quot;: [Array],</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>messages.errorMessages</td>
<td>Error messages encountered while processing the request. Data type: Array</td>
</tr>
<tr>
<td>messages.infoMessages</td>
<td>Information messages encountered while processing the request. Data type: Array</td>
</tr>
<tr>
<td>messages.warningMessages</td>
<td>Warning messages encountered while processing the request. Data type: Array</td>
</tr>
<tr>
<td>request</td>
<td>Original endpoint request. Data type: String</td>
</tr>
<tr>
<td>state</td>
<td>Information on the current state of the worker. Data type: Object</td>
</tr>
</tbody>
</table>
| state.display_value         | Display value of the state of the worker. These values directly correlate to the state.value parameter. Possible values:  
• Complete  
• Error  
• In-Progress  
• Waiting  
Data type: String |
| state.value                 | Numeric value of the state of the worker. Possible values:  
• Complete  
• Error  
• In-Progress  
• Waiting  |

<td>worker.link</td>
<td>Link for retrieving time slot data. Use the sys_id in GET /sn_chg_rest/change/worker/{sys_id} to view results.</td>
</tr>
<tr>
<td>worker.sysId</td>
<td>Sys_id of the worker associated with the change request.</td>
</tr>
<tr>
<td>status</td>
<td>Only appears if an error is encountered. Status of the endpoint processing. Possible values: failure</td>
</tr>
</tbody>
</table>

**Get available time slots**

Use the value provided in the `worker.link` to get schedule window details. The value is in the following format:

https://instance.service-now.com/api/sn_chg_rest/change/worker/<worker_sys_id>
Use the worker_sys_id in GET /sn_chg_rest/change/worker/{worker_sys_id} to view results.

The response body contains the status and provides results when processing is complete.

Worker response body parameter results vary depending on time slot availability.

- If the provided time slot is available for the change request within the schedule time slot, the worker API lists the available time slots in the payload.spans property. The payload.spans property is not listed in the results otherwise.

- If there are no time slots available for change request duration provided within the defined scheduling time slot, the messages.infoMessages states the following:

  No slots found for <number> days from <date and time in format yyyy-mm-dd hh:mm:ss>

  🔄 Note: The change request scheduling time slot default value is 90 days. To change this value, modify the change.conflict.next_available.schedule_window property. For more information, see Configure conflict analysis properties.

The following GET /sn_chg_rest/change/worker/{sys_id} example shows output provided using the ID provided in the worker.link detail. The results list open time spans available for the task duration.

```json
{
  "result": {
    "worker": {
      "sysId": "9b3f62e0a4c87010f87712198fe9cad1",
      "link": "https://instance.service-now.com/api/snchg_rest/change/worker/9b3f62e0a4c87010f87712198fe9cad1"
    },
    "request": {
      "change_sys_id": "87ae5e900a0a2c3e263e8304e727c646",
      "timezone": "America/Los_Angeles"
    },
    "state": {
      "value": 3,
      "display_value": "Complete"
    },
    "type": "schedule",
    "messages": {
```
"errorMessages": [],
"warningMessages": [],
"infoMessages": []
},

}
}

Example: cURL request

```bash
curl "https://instance.servicenow.com/api/sn_chg_rest/change/{change_sys_id}/schedule" \
--request GET \
--header "Accept:application/json" \
--user "username":"password"
```

Results include worker.link details you can use to run the provided sys_id in the GET /sn_chg_rest/change/worker/ endpoint.

```
{
"result": {
"worker": {
```
Change Management - GET /sn_chg_rest/change/{change_sys_id}/task

Retrieves one or more tasks associated with a specified change request based on the specified criteria.

**URL format**

**Versioned URL:** /api/sn_chg_rest/{api_version}/change/{change_sys_id}/task

**Default URL:** /api/sn_chg_rest/change/{change_sys_id}/task

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>change_sys_id</td>
<td>Sys_id of the change request whose tasks are to be retrieved. Located in the Change Request [change_request] table.</td>
</tr>
</tbody>
</table>
Path parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key-value pairs</td>
<td>Fields to modify when creating the request. The key is the field name within the template and the value is the information to populate in the field. Fields that cannot be modified and are ignored if passed in:</td>
</tr>
<tr>
<td></td>
<td>• Business rules</td>
</tr>
<tr>
<td></td>
<td>• Read-only fields as defined in ACLs</td>
</tr>
<tr>
<td></td>
<td>• Fields that do not exist</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>order</td>
<td>Field by which to sort the returned change requests. Default: number</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the <strong>sysparm_offset</strong> parameter to paginate record retrieval.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td></td>
<td>Default: 500</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks.</td>
</tr>
<tr>
<td></td>
<td>For example, the first time you call this endpoint, <strong>sysparm_offset</strong> is set to &quot;0&quot;. To simply page through all available records, use <strong>sysparm_offset=sysparm_offset+sysparm_limit</strong>, until you reach the end of all records.</td>
</tr>
<tr>
<td></td>
<td>Do not pass a negative number in the <strong>sysparm_offset</strong> parameter.</td>
</tr>
<tr>
<td></td>
<td>Data type: Number</td>
</tr>
<tr>
<td></td>
<td>Default: 0</td>
</tr>
<tr>
<td>sysparm_query</td>
<td>Encoded query used to filter the result set.</td>
</tr>
<tr>
<td></td>
<td><strong>Syntax:</strong> <strong>sysparm_query=&lt;col_name&gt;&lt;operator&gt;&lt;value&gt;</strong>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>&lt;col_name&gt;</strong>: Name of the table column to filter against.</td>
</tr>
<tr>
<td></td>
<td>• <strong>&lt;operator&gt;</strong>: Supports the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>=:</td>
<td>Exactly matches &lt;value&gt;.</td>
</tr>
<tr>
<td>!=:</td>
<td>Does not match &lt;value&gt;.</td>
</tr>
<tr>
<td>^:</td>
<td>Logically AND multiple query statements.</td>
</tr>
<tr>
<td>^OR:</td>
<td>Logically OR multiple query statements.</td>
</tr>
<tr>
<td>LIKE:</td>
<td>&lt;col_name&gt; contains the specified string. Only works for &lt;col_name&gt; fields whose data type is string.</td>
</tr>
<tr>
<td>STARTSWITH:</td>
<td>&lt;col_name&gt; starts with the specified string. Only works for &lt;col_name&gt; fields whose data type is string.</td>
</tr>
<tr>
<td>ENDSWITH:</td>
<td>&lt;col_name&gt; ends with the specified string. Only works for &lt;col_name&gt; fields whose data type is string.</td>
</tr>
<tr>
<td>&lt;value&gt;:</td>
<td>Value to match against.</td>
</tr>
</tbody>
</table>

All parameters are case-sensitive. Queries can contain more than one entry, such as
sysparm_query=<col_name><operator><value>[<operator><col_name><operator><value>]

For example:
(sysparm_query=caller_id=javascript:gs.getUserID()^active=true)

Encoded queries also supports order by functionality. To sort responses based on certain fields, use the ORDERBY and ORDERBYDESC clauses in sysparm_query.

Syntax:
- ORDERBY<col_name>
- ORDERBYDESC<col_name>

For example: sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory

This query filters all active records and orders the results in ascending order by number, and then in descending order by category.

If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the property glide.invalid_query.returns_no_rows. Set this property to true to return no results for an invalid query.
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>textSearch</td>
<td>String to use to search all change task record fields. This search uses ServiceNow full text search platform functionality and defaults to IR_AND_OR_QUERY. Data type: String</td>
</tr>
</tbody>
</table>

**Note:** The glide.invalid_query.returns_no_rows property controls the behavior of all queries across the instance, such as in lists, scripts (GlideRecord.query()), and web service APIs.

### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

#### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.
### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>All fields (key) with their associated values for the identified change request task prior to the delete.</td>
</tr>
<tr>
<td>parent</td>
<td>Information for the change request associated to the task.</td>
</tr>
<tr>
<td>parent.display_value</td>
<td>Change request information to display in a UI.</td>
</tr>
<tr>
<td>parent.value</td>
<td>Sys_id of the change request associated to the task.</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id information for the change request task.</td>
</tr>
</tbody>
</table>

```json
parent: {
    display_value: "String",
    value: "String"
}
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sys_id.display_value</td>
<td>Sys_id of the change request task to display in a UI. Data type: String</td>
</tr>
<tr>
<td>sys_id.value</td>
<td>Sys_id of the change request task. Data type: String</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```c
curl
  "https://instance.servicenow.com/api/sn_chg_rest/v1/change/0f4ac6c4b750230096c3e4f6ee11a9fe/task?sysparm_query=active=true"ORDERBYnumber"
--request GET
--header "Accept:application/json"
--user 'username':'password'
```

```json
{
  result: [
    {
      sys_id: {
        value: "12629ec4b750230096c3e4f6ee11a9d5",
        display_value: "12629ec4b750230096c3e4f6ee11a9d5"
      },
      parent: {
        value: "0f4ac6c4b750230096c3e4f6ee11a9fe",
        display_value: "CHG0033046"
      },
      ... // all valid fields in record, example below
      short_description: {
        value: "Retire node",
        display_value: "Retire node"
      }
    },
    ... // next record found }
  ]
}
```

**Python request**

```python
# Install requests package for python
import requests
```

</tr>
<tr>
<td>activity_due</td>
<td>Date and time for which the associated case is expected to be completed.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>additional_assignee_list</td>
<td>List of sys_ids of additional persons assigned to work on the change request. Data type: Array</td>
</tr>
<tr>
<td>approval</td>
<td>Type of approval process required. Data type: String Default: not requested</td>
</tr>
<tr>
<td>approval_history</td>
<td>Most recent approval history journal entry. Data type: String</td>
</tr>
<tr>
<td>approval_set</td>
<td>Date and time that the associated action was approved. Data type: String</td>
</tr>
<tr>
<td>assigned_to</td>
<td>Sys_id of the user assigned to the change request. Data type: String</td>
</tr>
<tr>
<td>assignment_group</td>
<td>Sys_id of the group assigned to the change request. Data type: String</td>
</tr>
<tr>
<td>backout_plan</td>
<td>Description of the plan to execute if the change must be reversed. Data type: String</td>
</tr>
<tr>
<td>business_duration</td>
<td>Length in scheduled work hours, work days, and work weeks that it took to complete the change. Data type: String</td>
</tr>
<tr>
<td>business_service</td>
<td>Sys_id of the business service associated with the change request. Located in the Service [cmdb_ci_service] table. Data type: String</td>
</tr>
<tr>
<td>cab_date</td>
<td>Date on which the Change Advisory Board (CAB) meets. Data type: String</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>cab_delegate</td>
<td>Sys_id of the user that can substitute for the CAB manager during a CAB meeting. Located in the User [sys_user] table. Data type: String</td>
</tr>
<tr>
<td>cab_recommendation</td>
<td>Description of the CAB recommendations for the change request. Data type: String Maximum length: 4,000</td>
</tr>
<tr>
<td>cab_required</td>
<td>Flag that indicates whether the CAB is required. Possible values: • true: Change Advisory Board is required. • false: Change Advisory Board is not required. Data type: Boolean Default: false</td>
</tr>
<tr>
<td>calendar_duration</td>
<td>Not currently used by Change Management. Data type: String</td>
</tr>
<tr>
<td>category</td>
<td>Category of the change, for example hardware, network, or software. Data type: String Default: Other</td>
</tr>
<tr>
<td>change_plan</td>
<td>Activities and roles for managing and controlling the change request. Data type: String</td>
</tr>
<tr>
<td>chg_model</td>
<td>Sys_id of the change model that the associated change request was based on. Located in the Change Model [chg_model] table. The Change Model defines the state flow, transitions, and process activities that must be completed for the change request.</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>

Change Management - GET /sn_chg_rest/change/{sys_id}/ci
Retrieves multiple configuration items (CIs) associated to a specified change request based on the specified association type.

URL format
Versioned URL: /api/sn_chg_rest/{api_version}/change/{sys_id}/ci
Default URL: /api/sn_chg_rest/change/{sys_id}/ci

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the change request for which to return the associated CMDB CIs. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>association_type</td>
<td>Required. Type of association between the CMDB CI and the change request. Valid values:</td>
</tr>
<tr>
<td></td>
<td>• affected: CIs that are affected by the change request</td>
</tr>
<tr>
<td></td>
<td>• impacted: Services impacted by the change request</td>
</tr>
<tr>
<td></td>
<td>• offering: Impacted service offerings</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>name-value pairs</td>
<td>Name-value pairs to use to filter the result set. The name is the field on which the specified value is filtered. This parameter is mutually exclusive with <code>sysparm_query</code>. For example, instead of using <code>&amp;sysparm_query=active=true</code>, you can simplify the calling statement by using <code>&amp;active=true</code>. You can also use the display value for the field if it is a choice or reference type field, such as <code>&amp;state=closed</code> instead of <code>&amp;state=7</code>. To specify multiple key-value pairs, separate each with an ampersand, such as <code>&amp;active=true&amp;assigned_to=john.smith</code>. Data type: String</td>
</tr>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the <code>sysparm_offset</code> parameter to paginate record retrieval. Data type: Number Default: 500</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records, regardless of the number of records, in small manageable chunks. For example, the first time you call this endpoint, <code>sysparm_offset</code> is set to &quot;0&quot;. Simply page through all available records, use <code>sysparm_offset=sysparm_offset+sysparm_limit</code>, until you reach the end of all records. Do not pass a negative number in the <code>sysparm_offset</code> parameter. Data type: Number Default: 0</td>
</tr>
<tr>
<td>sysparm_query</td>
<td>Encoded query used to filter the result set. Syntax: <code>sysparm_query=&lt;col_name&gt;&lt;operator&gt;&lt;value&gt;</code>. ----------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>• <code>&lt;col_name&gt;</code>: Name of the table column to filter against.</td>
</tr>
<tr>
<td></td>
<td>• <code>&lt;operator&gt;</code>: Supports the following values:</td>
</tr>
<tr>
<td></td>
<td>  ◦ <code>=</code>: Exactly matches <code>&lt;value&gt;</code>.</td>
</tr>
<tr>
<td></td>
<td>  ◦ <code>!</code>: Does not match <code>&lt;value&gt;</code>.</td>
</tr>
<tr>
<td></td>
<td>  ◦ <code>^</code>: Logically AND multiple query statements.</td>
</tr>
<tr>
<td></td>
<td>  ◦ <code>^OR</code>: Logically OR multiple query statements.</td>
</tr>
<tr>
<td></td>
<td>  ◦ <code>LIKE</code>: <code>&lt;col_name&gt;</code> contains the specified string. Only works for <code>&lt;col_name&gt;</code> fields whose data type is string.</td>
</tr>
</tbody>
</table>
## Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STARTSWITH: &lt;col_name&gt;</td>
<td>starts with the specified string. Only works for &lt;col_name&gt; fields whose data type is string.</td>
</tr>
<tr>
<td>ENDSWITH: &lt;col_name&gt;</td>
<td>ends with the specified string. Only works for &lt;col_name&gt; fields whose data type is string.</td>
</tr>
<tr>
<td>&lt;value&gt;</td>
<td>Value to match against.</td>
</tr>
</tbody>
</table>

All parameters are case-sensitive. Queries can contain more than one entry, such as:
```
sysparm_query=<col_name><operator><value>[<operator><col_name><operator><value>]
```
For example:
```
(sysparm_query=caller_id=javascript:gs.getUserID()^active=true)
```
Encoded queries also supports order by functionality. To sort responses by certain fields, use the `ORDERBY` and `ORDERBYDESC` clauses in `sysparm_query`.

**Syntax:**
- `ORDERBY<col_name>`
- `ORDERBYDESC<col_name>`

For example: `sysparm_query=active=true^ORDERBYnumber^ORDERBYDESCcategory`

This query filters all active records and orders the results in ascending order by number, and then in descending order by category.

If part of the query is invalid, such as by specifying an invalid field name, the instance ignores the invalid part. It then returns rows using only the valid portion of the query. You can control this behavior using the property `glide.invalid_query.returns_no_rows`. Set this property to true to return no rows on an invalid query.

ℹ️ **Note:** The `glide.invalid_query.returns_no_rows` property controls the behavior of all queries across the instance, such as in lists, scripts (`GlideRecord.query()`), and web service APIs.

Data type: String
Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see Supported REST API headers.

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

#### Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

### Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see REST API HTTP response codes.

#### Status codes

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Successful. The request was successfully processed.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected. The error response contains pertinent messages to help troubleshoot the problem.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
</tbody>
</table>
### Status codes (continued)

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>500</td>
<td>Internal server error. An unexpected error occurred while processing the request. The response contains additional information about the error.</td>
</tr>
</tbody>
</table>

### Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>`ci_item</td>
<td>cmdb_ci_service`</td>
</tr>
<tr>
<td></td>
<td>Data type: Array</td>
</tr>
<tr>
<td></td>
<td>`ci_item</td>
</tr>
<tr>
<td>`ci_item</td>
<td>cmdb_ci_service.value`</td>

<td>Data type: String</td>
</tr>
<tr>
<td>`ci_item</td>
<td>cmdb_ci_service.display_value`</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td><code>sys_id</code></td>
<td>Change request sys_id information.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>
<td><code>sys_id: { display_value: &quot;String&quot;, value: &quot;String&quot; }</code></td>
</tr>
<tr>
<td><code>sys_id.value</code></td>
<td>Sys_id of the change request.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td><code>sys_id.display_value</code></td>
<td>Sys_id of the change request to display in a UI.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>&lt;record_fields&gt;</td>
<td>All valid fields in the ci_item or cmdb_ci_service record; table based on association type. Data type: Object</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```bash
curl
   "https://instance.servicenow.com/api/sn_chg_rest/v1/change/c286d61347c12200e0ef563dbb9a71df/ci?association_type=affected"
   --request GET
   --header "Accept:application/json"
   --user 'username':'password'

{
   result: [
     {
       sys_id: {
           value: "92b8544047810200e90d87e8dee490b0",
           display_value: "92b8544047810200e90d87e8dee490b0"
       },
       ci_item|cmdb_ci_service : {
           value: "3a27d4370a0a0bb4006316812bf45439",
           display_value: "PS Apache01"
       },
       ..., // all valid fields in record, table based on association type
     },
     ..., // next record found }, ... // and so on
   ]
}
```

**Example: Python request**

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_chg_rest/v1/change/c286d61347c12200e0ef563dbb9a71df/ci?association_type=affected'

# Set the user credentials
user = 'username'
```
pwd = 'password'

# Set the proper headers
headers = {"Accept":"application/json"}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.json())
    exit()

# Decode the JSON response into a dictionary and use the data
data = response.json()
print(data)

{
    result: [
        {
            sys_id: {
                value: "92b8544047810200e90d87e8dee490b0",
                display_value: "92b8544047810200e90d87e8dee490b0"
            },
            ci_item|cmdb_ci_service : {
                value: "3a27d4370a0a0bb4006316812bf45439",
                display_value: "PS Apache01"
            },
            ... // all valid fields in record, table based on association type
        },
        { // next record found }, ... // and so on
    ]
}

**Change Management - GET /sn_chg_rest/change/{sys_id}/conflict**

Retrieves the status of the currently running change request conflict checking process or the results of the last completed conflict checking process for the specified change request.

**URL format**

Versioned URL: /api/sn_chg_rest/{api_version}/change/{sys_id}/conflict
Default URL: /api/sn_chg_rest/change/{sys_id}/conflict

### Supported request parameters

#### Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the change request for which to return the status of the running/completed conflict checking process. Located in the</td>
</tr>
<tr>
<td></td>
<td>Change Request [change_request] table.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
</tbody>
</table>

#### Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

#### Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

### Headers

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).

#### Request headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>
Response headers

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>

Status codes

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Current status of the conflict checking process; including conflicts if any are detected.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>

Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>conflicts</td>
<td>List of conflicts found for the change request. An empty object indicates that no conflicts were detected. Data type: Array</td>
</tr>
<tr>
<td>job_status</td>
<td>Status of the actual conflict checking job. Data type: String</td>
</tr>
<tr>
<td>last_run</td>
<td>Date and time the last conflict checking process started. Data type: String</td>
</tr>
<tr>
<td>record_count</td>
<td>Number of records checked. Data type: String</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>status</td>
<td>Outcome of the conflict checking process, such as &quot;Conflict&quot; or &quot;Not run&quot;.</td>
</tr>
</tbody>
</table>

**Note:** Even if the change request does not have any conflicts, this field is set to "Conflict." However, the `conflicts` object is empty.

Data type: String

### Example: cURL request

**curl**

```bash
curl "https://instance.servicenow.com/api/sn_chg_rest/v1/change/0f4ac6c4b750230096c3e4f6e11a9fe/conflict" \   --request GET \   --header "Accept:application/json" \   --user "username":"password"
```

**Successful response - no conflicts**

```json
{
    result: {
        status: "Conflict",
        last_run": "2018-08-30 12:58:05",
        record_count: "1",
        job_status: "2",
        conflicts: []
    }
}
```

### Example: cURL request

**curl**

```bash
curl "https://instance.servicenow.com/api/sn_chg_rest/v1/change/0f4ac6c4b750230096c3e4f6e11a9fe/conflict" \   --request GET \   --header "Accept:application/json" \   --user "username":"password"
```

**Successful response - with conflicts**

```json
{
    result: {
        status: "Conflict",
        last_run": "2018-08-30 12:58:05",
```
record_count: "1",
job_status: "2",
conflicts: [
  {
    change: {
      display_value: "CHG0030001",
      value: "afbffb24b758230096c3e4f6ee11a972"
    },
    type: {
      display_value: "Not In Maintenance Window",
      value: "not_in_maintenance_window"
    }
  }]

Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.service-now.com/api/sn_chg_rest/v1/change/0f4ac6c4b750230096c3e4f6ee11a9fe/conflict'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {"Accept":"application/xml"}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()
```
# Decode the XML response into a dictionary and use the data
print(response.content)

Successful response - no conflicts

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
    <result>
        <status>Conflict</status>
        <last_run>2018-08-30 12:58:05</last_run>
        <record_count>1</record_count>
        <job_status>2</job_status>
        <conflicts/>
    </result>
</response>
```

Change Management - GET /sn_chg_rest/change/emergency

Retrieves one or more emergency change requests based on the specified criteria.

**URL format**

Versioned URL: /api/sn_chg_rest/{api_version}/change/emergency

Default URL: /api/sn_chg_rest/change/emergency

**Supported request parameters**

**Path parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

**Query parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>order</td>
<td>Field by which to sort the returned change requests. Default: number Data type: String Default: number</td>
</tr>
</tbody>
</table>
**Query parameters (continued)**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sysparm_limit</td>
<td>Maximum number of records to return. For requests that exceed this number of records, use the <code>sysparm_offset</code> parameter to paginate record retrieval. Data type: Number Default: 500</td>
</tr>
<tr>
<td>sysparm_offset</td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate record retrieval. This functionality enables the retrieval of all records regardless of the number of records, in small manageable chunks. # Set the proper headers
headers = {'Accept': 'application/xml'}

# Do the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:',
          response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)
```

```xml
<?xml version="1.0" encoding="UTF-8"?>
<response>
  <result>
    <sys_id>
      <value>1c87925347c12200e0ef563dbb9a7177</value>
      <display_value>1c87925347c12200e0ef563dbb9a7177</display_value>
    </sys_id>
    <state>
      <value>-5</value>
      <display_value>New</display_value>
    </state>
    <type>
      <value>emergency</value>
      <display_value>Emergency</display_value>
    </type>
  </result>
</response>
```
Change Management - GET /sn_chg_rest/change/emergency/{sys_id}
Retrieves the emergency change request identified by the specified sys_id.

URL format
Versioned URL: /api/sn_chg_rest/{api_version}/change/emergency/{sys_id}
Default URL: /api/sn_chg_rest/change/emergency/{sys_id}

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id of the emergency change request to retrieve from the Change Request [change_request] table. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
Request body parameters (XML or JSON)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

**Headers**

The following request and response headers apply to this HTTP action only, or apply to this action in a distinct way. For a list of general headers used in the REST API, see [Supported REST API headers](#).

**Request headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>Data format of the response body. Supported types: application/json or application/xml. Default: application/json</td>
</tr>
</tbody>
</table>

**Response headers**

<table>
<thead>
<tr>
<th>Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>None</td>
</tr>
</tbody>
</table>

**Status codes**

The following status codes apply to this HTTP action. For a list of possible status codes used in the REST API, see [REST API HTTP response codes](#).

**Status codes**

<table>
<thead>
<tr>
<th>Status code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Request completed successfully.</td>
</tr>
<tr>
<td>400</td>
<td>Bad Request. A bad request type or malformed request was detected.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user credentials are incorrect or have not been passed.</td>
</tr>
<tr>
<td>404</td>
<td>Not Found. The specified record could not be found.</td>
</tr>
<tr>
<td>500</td>
<td>Internal Server Error. A logic error on the server-side code occurred.</td>
</tr>
</tbody>
</table>
## Response body parameters (JSON or XML)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Values for all fields in the associated change request.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td>state</td>
<td>State of the change request.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>
<td>state: {</td>
</tr>
<tr>
<td></td>
<td>display_value: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>value: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>state.display_value</td>
<td>State to display in a UI.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>state.value</td>
<td>Internal state value.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id</td>
<td>Sys_id information for the change request.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>
<td>sys_id: {</td>
</tr>
<tr>
<td></td>
<td>display_value: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>value: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>sys_id.display_value</td>
<td>Sys_id of the change request to display in a UI.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>sys_id.value</td>
<td>Sys_id of the change request.</td>
</tr>
<tr>
<td></td>
<td>Data type: String</td>
</tr>
<tr>
<td>type</td>
<td>Type of change request.</td>
</tr>
<tr>
<td></td>
<td>Data type: Object</td>
</tr>
<tr>
<td></td>
<td>type: {</td>
</tr>
<tr>
<td></td>
<td>display_value: &quot;String&quot;,</td>
</tr>
<tr>
<td></td>
<td>value: &quot;String&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>type.display_value</td>
<td>Change type to display in a UI.</td>
</tr>
</tbody>
</table>

**Example: cURL request**

```bash
curl
"https://instance.servicenow.com/api/snchg_rest/v1/change/emergency/b0dbda5347c12200e0ef563dbb9a718f"
--request GET
--header "Accept:application/json"
--user "username":"password"
```
Example: Python request

```python
# Install requests package for python
import requests

# Set the request parameters
url = 'https://instance.servicenow.com/api/sn_chg_rest/v1/change/emergency/b0dbda5347c12200e0ef563dbb9a718f'

# Set the user credentials
user = 'username'
pwd = 'password'

# Set the proper headers
headers = {'Accept': 'application/xml'}

# Make the HTTP request
response = requests.get(url, auth=(user, pwd), headers=headers)

# Check for HTTP codes other than 200
if response.status_code != 200:
    print('Status:', response.status_code, 'Headers:', response.headers, 'Error Response:', response.content)
    exit()

# Decode the XML response into a dictionary and use the data
print(response.content)

<?xml version="1.0" encoding="UTF-8"?>
<response>
    <result>
        <sys_id>
            <value>b0dbda5347c12200e0ef563dbb9a718f</value>
            <display_value>b0dbda5347c12200e0ef563dbb9a718f</display_value>
        </sys_id>
        <state>
            <value>-5</value>
            <display_value>New</display_value>
        </state>
        <type>
            <value>emergency</value>
            <display_value>Emergency</display_value>
        </type>
    </result>
</response>
```
Change Management - GET /sn_chg_rest/change/model

Retrieves one or more change models based on the specified criteria.

Use this endpoint to find a change model that best fits the change request that you are trying to create. For additional information on change models, see Change Models.

URL format

Versioned URL: /api/sn_chg_rest/{api_version}/change/model

Default URL: /api/sn_chg_rest/change/model

Supported request parameters

Path parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>api_version</td>
<td>Optional. Version of the endpoint to access. For example, v1 or v2. Only specify this value to use an endpoint version other than the latest. Data type: String</td>
</tr>
</tbody>
</table>

Query parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name-value pairs</td>
<td>Name-value pairs to use to filter the result set. The name is the field on which the specified value is filtered. This parameter is mutually exclusive with sysparm_query. For example, instead of using &amp;sysparm_query=active=true, you can simplify the calling statement by using &amp;active=true. You can also use the display value when the field is a choice or reference type field, such as &amp;state=closed instead of &amp;state=7. To specify multiple key-value pairs, separate each with an ampersand, such as &amp;active=true&amp;assigned_to=john.smith.</td>
</tr>
</tbody>
</table>
### Query parameters (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td><strong>order</strong></td>
<td>Field by which to sort the returned change models.</td>
</tr>
<tr>
<td>Data type: String</td>
<td></td>
</tr>
<tr>
<td><strong>sysparm_offset</strong></td>
<td>Starting record index for which to begin retrieving records. Use this value to paginate</td>
</tr>
<tr>
<td></td>
<td>record retrieval. This functionality enables the retrieval of all records regardless of the</td>
</tr>
<tr>
<td></td>
<td>number of records, in small manageable chunks.</td>
</tr>
<tr>
<td></td>
<td>For example, the first time you call this endpoint, <code>sysparm_offset</code> is set to &quot;0&quot;.</td>
</tr>
<tr>
<td></td>
<td>Simply page through all available records, use <code>sysparm_offset=sysparm_offset+sysparm_limit</code></td>
</tr>
<tr>
<td></td>
<td>until you reach the end of all records.</td>
